COAL AGE

With Which Is Consolidated
The Colliery Engineer

INDEX TO VOLUME XV

January 1 to June 30, 1919

Note—Illustrated articles are denoted by an asterisk (*), book notices by a dagger (†). Titles are often abbreviated. They are indexed under their most important words, or, if no word be distinctive, under their first one (except "A," "The," etc.), or under some topical word not found in the title. Authors', geographical and other proper names are also used freely.

Following is a list of the pages included in the several numbers of the volume by date:

Jan. 2	Pages	1– 42
" 9	"	43– 80
" 16	"	81– 172
" 23	"	173– 216
" 30	"	217– 258
Feb. 6	"	259– 304
" 13	"	305– 346
" 20	"	347– 388
" 27	"	389– 430
Mar. 6	"	431– 476
" 13	"	477– 518
" 20	"	519– 560
" 27	"	561– 604
April 3	"	605– 650
" 10	"	651– 694
" 17	"	695– 740
" 24	"	741– 780
May 1	"	781– 844
" 8	"	845– 894
" 15	"	895– 936
" 22	"	937– 980
" 29	"	981–1024
June 5	"	1025–1070
" 12	"	1071–1108
" 19	"	1109–1148
" 26	"	1149–1194

A

Accident compensation and cost of living equalized 152
Accident to motorman 1001
Accidents by nationality, Coal mine...1044, 1091
Accidents from handling explosives 1134
Accidents, Penn., 1918. Hall *90
Accidents to footmen 652
Accounting, Correct (inq.), 248. Discussion 501, 828, 875
Accounting, Mine supply 1091
Accounting—Monroe calculating machine... 816
Accounting of materials. Discussion 66
Acid solutions, Mixing (inq.) 880
Aerial tramway. Discussion 459, 827
Aerial tramway, Coal transportation by. Grice *808
After the manner of his kind 496
Air compressors, Lubrication. Conrad *704
Air, Dew point in mine (inq.) 831
Air entering coal mines? Is it safe to dry.. 1005
Airway, Enlarging an (inq.) 637
Alabama, production 1918. Nesbitt..82, 837, 1184
Alarm in case of mine fire 983
Alaska, coal. (Notes) 36, 73
Alaska coal field, Navy will survey 626
Alaska, coal policy 913
Alaska coal review, 1918. Smith 82
Alaska, Eska, Reserve coal deposits at Gov't mine. Smith *940
Alberta, 1918 coal review. Stirling *97
Alberta, coal production 748, 973
Algeria, coal situation 882
Algerian market for American coal. Frost. 309
Alsace-Lorraine, German coal in 640
Alsace-Lorraine, Severance of 107
Ambitions, Every period has its own. Hall. 1071
America's opportunity in foreign markets. Parsons 651
American Coal Exporters 149
Amer. Inst. of Mg. Engrs—Program, 237. Paper, 314. Meetings 448, 868
American Job and his comforters 627
Amer. Mg. Congress—Export problem 867
American opportunities in foreign coal trade 486
Amer. Wholesale Coal Assn.—Program 913
Analyses, Canadian coals 746, 860
Analyses, coal *1150
Annealing, A little matter of 403
Anthracite, allotment, domestic, 1918-19 109
Anthracite, amount unmined. (Note) 251
Anthracite committee goes out of existence.. 283
Anthracite for Scotland 421
Anthracite, Gov. Sproul withdraws criticisms 712
Anthracite industry, 1918. Parker *108
Anthracite miners discharged from army... 151
Anthracite mines, electric power in 706
Anthracite mining costs. Norris *1124
Anthracite, New England, 1918. Wolkins.. 130
Anthracite, Penn., 1918. Hall *90
Anthracite receipts at Boston 115
Anthracite restrictions removed. (Notes)... 165
Anthracite, shipments and value 1917 and 1918 1024
Anthracite ton weight 1016
Argentina, cost of fuel 833
Arkansas, 1918. Speegle 83
Ash conveyor, steam jet. Hamilton *807
Assessment, coal 914, 1016
Associations, local coal 190
Associations, Plague of. Seaburg 453
Augur, Clever, can find whatever he will.... 455
Augurs, Too great a levity among the 761
Automatic reclosing circuit breakers. Raney. *800

B

Baldwin, A. J. Coal industry of France... *276
Baltimore & Ohio—Statement 42
Baltimore coal trade, 1918 270
Baltimore tunnel flare-up. 1076, *1109, *1128, 1183
Barking up the wrong tree. Kneeland 574
Barometer vs. outflow of gas. Discussion, 634, 1009, 1054
Bathhouses in Utah. Watts *4
Belgian Kongo, coal mining in 834
Belgium, coal situation 1140
Belting used in anthracite breakers (inq.), 419. Discussion 726
Belts of paper, Germans use driving 569
Better wait till limb gets stouter. (Poster).. 196
Bids, War Dept. will open coal 774
Bill of lading, Uniform 912
Bituminous coal, Preparation of. Prochaska, 943, 960, 986, *1030, *1080, *1118
Bituminous price lifted 191
Bituminous receipts at Boston 116
Blackdamp on pitches. Discussion 157
Blacksmith, mechanical *799
Blackwood Coal & Coke Co.—New tipple. Sharon *796

BLASTING

—Exam. questions 336, 465, 592
—Firing time, Reducing ventilation. Discussion 69, 290, 588, 635, 1054
—Heavy paper tamping bags 1039
—Shotfiring, Safety in. Discussion 416
Blowers, steam. Effect on combustion. Owens 53
Blue Diamond Coal Co.—Diagonal crosscuts. Sherwin *218
Boat, last of season. (Photo) 135
Boiler fuel economy. Meredith 617
Boilers, steam-flow meter 955
Boilers—Tools for cleaning fires *983
Bolshevism and other "isms" 1050
Bolshevism, Essentials of 915
Bon Air Coal & Iron Corp.—pyrite 1077
Bonus payments to shovelers 362
Book reviews 365, 551, 593, 639
Boomerang, A queer weapon is the (Poster). 1007
Bottle with two necks 1131
Box-car loader at modern mine. (Cartoon). 577
Boy scouts of Raleigh, West Va. *406
Bradford coal breaker *352
Brazil coal, Stoking 208
Brazil—Coal exports, 508. Imports...928, 1015
Breathing apparatus, self-contained 272
Briquets, Output of fuel 438
Briquetting, anthracite buckwheat 1089
Briquetting plant of Johnson Fuel Co 775
British Columbia, coal analyses 860
British Columbia, Coal in Peace River district. Dunn 1085
British Columbia, production, 1918. Wilkinson, *97. Table 858
British Columbia Int. Mg. Convention. Dunn 666
British Columbia, mining bill. Dunn, 524. Operators object to new features 571
British Guiana, coal imported 882
Bruceton experimental mine *308, *676
Brush, Unique tube. Willey *982
Bucket, Water scuttle or. Luxton *897
Buckeye Coal Co.—Development of coal land 265
Buffalo coal markets in 1918. Chamberlin..*137
Bumps and outbursts of gas in Crowsnest Pass *660
Burrell, G. A 403
Bunker licenses 192, 337
Bureau of Foreign & Domestic Commerce—Exports, U. S 379

BUREAU OF MINES

—Accidents by nationality, Coal mine. 1044, 1091
—Analyses of coals *12
—Combustion. (Notes) 265
—Commission to visit French mines 408
—Experiment station tests *1150
—Fuel inspection system 1129
—Fusibility of ash. Selvig, Ratliff and Fieldner 698
—Fusibility of ash from Penn. coals. Selvig and Fieldner 1086
—Lignite treatment investigations 325, 1169
—Moving pictures of coal industry 367, 1064
—Pittsburgh station, new. Harris, *707, *749, *852, *907
—Pyrite in east and middle west states 756
—Work during 1918. Manning *105
—Velocity of ventilating current on mine explosions. Rice and Egy *308
Burrell gas detector. Discussion 1094
Burton-Furber Coal Co.—Wharf. (Photos).. 117
Bushings for car wheels. Humphrey 652
Business outlook in America. Keith *114
Buy, buy, buy 369
Buyers have duties but no consciences 760

C

Cable, Breaking of. Dunn *489
Cage safety, Increasing. Price *570
Cages, Self-dumping 799
Calculating machine 816
California coal rich in oil 703
Canada, Coal production, 1918 1044
Canada, Coal resources of western. White, *744, *858
Canada West Coal Co—Ash conveyor. Hamilton *807
Canadian Western Fuel Co.—Breaking cable. Dunn, *489. Cage safety. Price *570
Canals, coal passing through 36
Canary Islands lost bunker trade in 1917... 730
Candlepower in lighting (inq.) 1099
Cannel coal in Texas 991
Cannel coal, Oil from 1035
Carbon and commutator wear. Hellund 307
Carbon as a fertilizer, 52. Discussion 546
Carbide cans, Uses for empty. Humphrey.. 743
Carbon dioxide recorder 611
Carbonization of Illinois coals in inclined gas retorts 803
Carbonizing process, G-L low temperature, *810, 822
Car dumping machine. (Photos) 125, 129
Car, New type of mine *809
Car shortage 553, 1101, 1142, 1183
Car, solid-body mine *805
Car wheels, Bushings for. Humphrey 652
Cars, Cost upkeep of mine. Discussion 460
Cars, Device for holding *742
Cars, Iron vs. wood mine. Discussion..157, 461
Cars loaded in 1918 186
Cars, Lubricating mine (inq.), 377. Discussion 768
Cars, moving, on switch 478
Cars, roller bearing 245
Cars, Standardization of mine. Brown *793
Cartoons, 286, 328, 412, 479, 539, 577, 629, 718, 871, 905
Cascade Coal & Coke Co.—Washery refuse. 850
Catch-all, Handy. Willey *1026
Cause, The. Braley 621
Caves, mine 35, 468
Cement lining on airways 269
Centerville Block Coal Co.—Mine hoist.... *669
Centrifugal mine pumps. Discussion 66, 245
Certification and safety. Discussion, 374, 723, 766, 1010, 1094, 1177
Chain making and repairing. Springer.... *220
Chain repairs. Willey *562
Chain, sprocket *809
Chairman of mining committee of House of Representatives 538
Chart—Bureau of foreign and domestic commerce 299
Chart—Efficiency of different washers 1031
Chart—Flow meter 51
Chart, Pressure. (inq.), Harry, *728. Discussion 1133
Chart—Production, coal, 1915-1918 99
Chart—Products derived from coal 1152
Chart—Rest period in shoveling 358
Chart—Water power development in U. S.. 226
Charts—Petroleum. Breckenridge *127
Chemistry and constitution of coal. Fieldner *1150
Chicago, Wilmington & Franklin Coal Co.—Hoisting record 532, 799, 1180
Chronology 204, 468, 553, 773, 972, 1141
Cincinnati market conditions, 1918. Crain..*188
Clark, W. A. Portrait 616
Classification, coal 187
Cleveland coal situation in 1918. Boehringer 179
Closing down mines, 210, 295, 338, 382, 510, 774, 930
Coal Age—Index ready 235. Suggestions for I. & S. dept. 563. Five dollars for best photo 623

EXAMINATION QUESTIONS
—Ala. firebosses—Mine gases, safety lamp, ventilation *729
—Ala. first class—Safety, ventilation, blasting, 465. Blasting, coal handling, brattices and overcasts, abandoned workings 507
—Ala. second class—Blasting, timbering, squeeze, pillar working, ventilation..... 592

Page

EXAMINATION QUESTIONS—Continued
—Bituminous (Penn.) firebosses—Duties of fireboss, danger signals, approved safety lamps, timbering 1181
—Bituminous mine foremen—Mining law, duties of mine foremen, haulage, driving entries, first aid, 881. Ventilation, coal dust, anemometer readings, stoppings, intake and return airways, plunger pump 925
—British Columbia—Instruments, working gases, ventilation, 203. Shotfiring, gases, lamps, barometer, 249. Gases, safety lamps, explosions, 294. Blasting, gases, ventilation, 336. Overcasts, ventilation, *1059. Ventilation, fans, haulage, 1100. Fans, barometer, electricity, watering, pumping *1139
—Hoisting engineers—Steel hoisting rope, steam, unit of heat, boilers, natural and forced draft, pipe fittings..... 770
—Mine examiners'—Duties of mine examiner, regulator, ventilation, mine gases, 550. Ventilation, mine gases, Davy safety lamp *638
—Mine managers'—Mine gases, electricity, pumping, 378. Ventilators, timbering, working, hoisting 420
—Misc.—Coal dust, ventilation, instruments, mine fires 162
—Misc.—Haulage dangers, hoisting in slope, safety devices at shaft, testing safety devices, horsepower of haulage engines .682
—Misc.—Timbering, first aid, mine gases, ventilation 33
—Misc.—Ventilation, rope, mine gases, shotfiring 72
—Misc.—Ventilation, pumping, equipment for care of injured, accidents..... 832
—Misc.—Ventilation, anemometers, safety valve, horsepower of fan, 970. Correction 1181
Exhaust from steam pump (inq.), 549. Discussion *826, 876, *964, *1097, 1179
Expediting locomotive haulage. Discussion 244

EXPLOSION. See also "Dust," "Gases, Mine," "Ventilation."
—Baltimore tunnel.....1076, *1109, *1128, 1183
—Exam. Questions 294
—Explosions. (Notes).....35, 73, 687, 975, 1064
—Majestic Coal Co..... 885
—Pettebone mine 885
—Velocity of ventilating current on mine explosions. Rice and Egy, *308. Discussion *676
Explosive, Nitro-Starch as..... 235
Explosive—Safety detonator 348
Explosive testing plant in Canada.....1185
Explosives and blasting caps. (Poster)..... 63
Explosives, delivery to miners.....1183
Explosives, Efficient storage. Atwood..... 232
Explosives, Leave your, outside. (Poster).. 874
Explosives, Liquid oxygen.....1002
Explosives, Pittsburgh station Bureau of Mines *911
Explosives, Safe handling. Discussion....1134
Explosives—"Sengite." Meredith..... 857
Explosives, storage, at coal mines. Kimball..*794
Exports. See "Trade."
Extending coal operator's field for profits. Cushing 534

COAL AGE

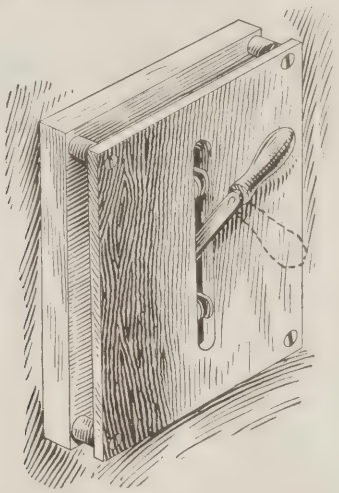
Volume 15 — New York, January 2, 1919 — *Number* 1

The Question

Written expressly for *Coal Age*
By BERTON BRALEY

OH, lots of you guys discussin'
The way that our soldiers fight,
Are shoutin', "We licked the Prussian,
We gave him the gaff, all right.
We surely were smashin' an' crushin',
The soldiers of Schrecklichkeit."
But me, I listens to what you say
And asks you, "How do you get that way?"

WHERE do you get that "We" stuff?
That's what I want to ask.
Some of you has the right to talk,
Them that has done their task.
But you that has loafed and loitered,
Earnin' one half your pay,
Where do you get that "We" stuff?
How do you get that way?



OH, I have heard fellers chinnin'
How "We" were a-pushin' through,
How splendidly "We" were winnin'
And breakin' the Boche in two.
And ever since the beginnin',
Plain slackin' was all *they'd* do.
And me, I listens to what they spout
And then, impatient, I hollers out—

WHERE do you get that "We" stuff?
That's what I want to know.
Slackers that never had done their job
Hasn't no right to blow.
Workers that done their duty,
They kin say "Us" and "We,"
But unless you labored and saved your share
Don't holler what "We" did over there,
You haven't the right, you see!
You that was livin' easy,
Slowin' things up each day,
Where do you get that "We" stuff?
How do you get that way?

IDEAS AND SUGGESTIONS

Safety Switch Shield Protects Against Electric Shock

The accompanying illustration shows a protection against electric shock, which is liable to occur to those handling knife switches located in dark places. To avoid such occurrences a board of suitable dimensions

with a slot cut in it long enough for the travel of the switch blade, is fastened to the switch plate by means of four screws passing through insulating distance pieces. The hinged handle facilitates the motion of the blade in both directions.

Construction of a Bell-Ringing Transformer for Signaling Apparatus*

BY GEORGE F. DESILVER
St. Louis, Mo.

It is now generally appreciated that in places where 110-volt alternating current is available a bell-ringing transformer makes the most satisfactory device for furnishing current for the operation of signaling apparatus such as call bells, annunciators and alarm signals. A

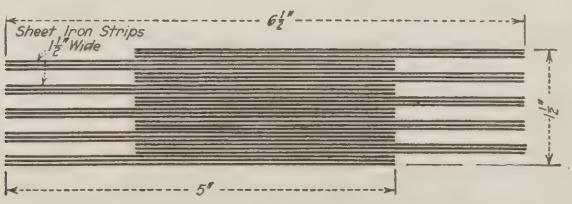


FIG. 1. METHOD OF MAKING CORE OF STRIPS

transformer which, when 110 volts is impressed on its primary will deliver either 3, 6, 9, 12, 15 or 18 volts at its secondary, can be constructed as shown in Figs. 1, 2 and 3.

The core is built up of sheet-iron strips. The softest sheet iron available should be used, and it should be as thin as it is possible to secure. To insure that the sheets will be thoroughly annealed they should be heated to a red heat and then cooled very slowly. Cut from this sheet-iron material a sufficient number of strips *A*, Fig. 3, 1½ x 3¼ in., to make a pile 3 in. thick. Also cut enough strips *B*, 1½ x 5 in., to make a pile 3 in. thick. The strips *B* should then be piled into a core in the manner illustrated in Fig. 1. After being assembled into this core, the strips should be clamped securely and wrapped with three or four layers of friction tape, so that they will be held in a compact mass.

The core should be wound as follows: On each leg, as shown in Fig. 2 for the secondary, wrap about 2½ lb. of No. 12 double cotton-covered copper wire. There

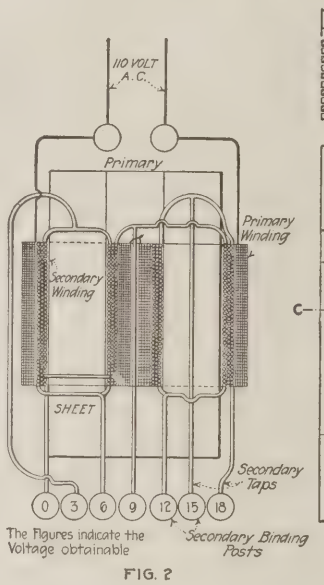

FIG. 2

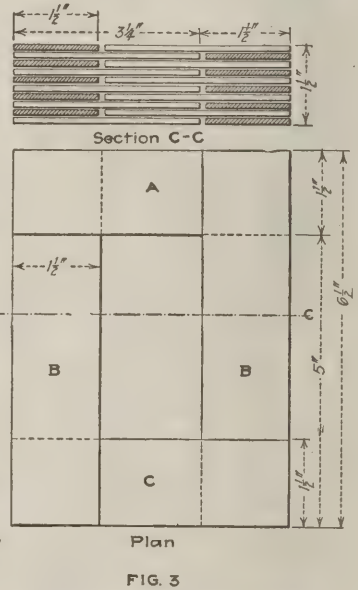

FIG. 3

FIGS. 2 AND 3. HOW TO MAKE THE WINDINGS

should be three layers of 25 turns to the layer. This secondary is connected to the binding posts as follows, and as shown in Fig. 2. As each layer is completed a tap is carried to one of the binding posts. The wire with which the secondary winding starts is connected to post 0. From the end of the first layer a tap is carried to post 3. From the end of the next layer, a tap is carried to post 6. Taps are carried to the posts systematically in the manner suggested, and as shown in Fig. 2. The secondary winding is of course in one continuous length on each leg, and the connections to the binding posts are taps soldered thereto. The windings should be in such direction that they will correspond to those shown in Fig. 2.

The primary winding, upon which 110 volts is impressed, is wound over the secondary. It consists of about 6 lb. of No. 22 single cotton-covered copper wire. There should be about six layers with 67 turns to each layer. For insulation between the primary and secondary there should be used a stiff strong paper. Good bond writing paper will suffice. As each primary and

*Copyrighted.

secondary layer is completed it should be thoroughly soaked with shellac, so that when the winding is complete it will set into a compact mass.

After the windings on the legs are completed, the 3¼-in. strips *A* (Fig. 3) can be inserted, as shown in that illustration, between the ends of the strips *B*, to complete the magnetic circuit. To hold the *B* strips in position on the legs and to clamp the transformer to a back board, wooden straps can be utilized. These straps should be so arranged parallel to the iron strips *A* that they will bind the whole transformer down against a wooden base block. Small machine bolts are inserted in the wood straps to effect the clamping action necessary.

Cautions To Be Observed When Testing Dry Cells

In testing dry cells, small-diameter wires should not be used for the ammeter leads. These conductors should be not more than 12 in. long and of a cross-sectional area equivalent to at least that of No. 12 wire.

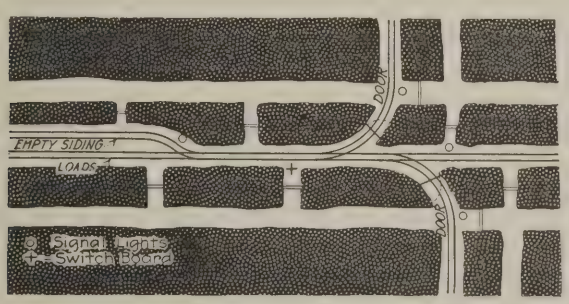
The ammeter leads should not be held on the binding post of the cell under test for more than 2 or 3 sec. at a time. An ammeter connected directly across the terminals constitutes an almost "dead short-circuit" and will therefore quickly "exhaust" and spoil the cell. Always hold the ammeter lead terminals on the brass binding posts of the cell; it is not good practice to hold the end of one ammeter lead on the upper end of the carbon and the other on the edge of the zinc casing.

Finally, be certain that the ammeter or battery tester which you are using is correct. The value of your test depends wholly on the accuracy of the testing instrument. Hence, the ammeter should be compared often with a standard instrument which is known to be absolutely accurate.

Electric Signal System That Eliminated Collision Troubles

By Orin Kelly
Columbus, Ohio

The accompanying illustrations show a signal system designed by myself for one of the large mines in Ohio where considerable trouble was occasioned by collisions



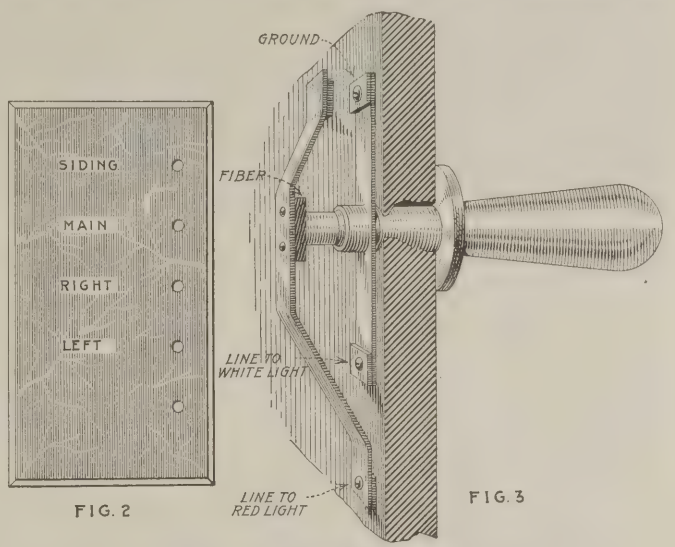


FIG. 1. SHOWING POSITION OF SIGNAL BOXES

between haulage locomotives. These took place at a point where three motors gathered the coal to a common siding by an arrangement of switches, as shown in Fig. 1.

Doors were provided at the entrances to the right and left entries, and a boy was stationed here to attend to them and to flag for the motors. It was found, however, that a better system was needed, and that shown in the sketches was designed.

Four wooden boxes were made, each provided with two electric lamps, one red and the other white. The boxes were painted white inside and had wire netting over the front to protect the lamps. These signal boxes were placed at the points marked by circles in Fig. 1, these points being such as to give the motorman a clear view of the signal in time to stop his trip before passing the signal box. The motormen were instructed not

FIGS. 2 AND 3. CONSTRUCTION DETAILS OF SWITCHBOARD

to pass any signal station unless the signal light then burning was white. These signals are operated by the trapper from a switchboard placed at the point marked with a cross.

Figs. 2 and 3 show the construction of the switchboard. The circuit to the red light is kept closed by a spring contact until it is opened by the insertion of the switch plug which, while it opens the circuit to the red lamp, closes that to the white. As only one switch plug is furnished it is impossible to give a clear signal at more than one place at one time, all others showing red. It will be seen that each motorman moves through this common meeting point only on positive signal, and when this shows clear. No other motor can get through without running by a red block, in which case the position of the signals fixes the blame at once and without question.

In order that the men engaged in rescue work at a mine following an explosion or accident may render most efficient service they must have a comfortable place for rest and sleep. While men are sleeping they should not be disturbed by those who are off duty and awaiting their shift. Hence sleeping quarters should be provided to accommodate half of the total number of men employed in rescue and recovery operations, as at no time will more than half the men be off duty. The rest room should be separate and apart from the sleeping quarters so that men who are sleeping will not be disturbed.—*Rescue and Recovery Operations in Mines.*

Mine Bathhouses in Utah

By A. C. WATTS
Salt Lake City, Utah

SYNOPSIS — *Bathing facilities at mines were formerly decidedly crude and inadequate. In a mountainous country many considerations besides the water supply and necessary heating arrangements enter into the design of a bathhouse. These have been solved with a fair degree of satisfaction, and many miners now refuse to work at a mine that has no washhouse.*

MANY years ago, after coming out of a coal mine for the first time in my life, I solemnly vowed never to go into another. It was not because of being afraid of the dark, or of the many dangers present in all coal mines; for there were many lights, and there was also an entire lack of knowledge of the dangers. But the resolution was due to the dirt which soiled everything and the black hands and faces and sooty nostrils of all the workmen.

We were a party of students, members of the graduating class of a famous Western mining school, and we were making an inspection trip. With us was our professor of metallurgy, who, because of a cherished beard of fiery hue, was called "Pink Whiskers." On our way out we passed through a door which was guarded by a vicious trapper, sporting an enormous oil lamp on which had accumulated a luxurious growth of oil and soot. Seeing a bunch of greenhorns coming, he carefully anointed his hands from his lamp and then proceeded to wipe them on the faces of the unwary students, not omitting "Pink Whiskers," whose pride and dignity were much hurt thereby. A poor trapper boy is not supposed to know a learned professor on sight anyway. It made a great impression on one young mind, more particularly because there was no means of getting clean until we had reached our hotels at night.

A short time after, through one of the ironies of fate, I found myself earning (or trying to earn) my living as a surveyor in that same coal mine and others operated by the same company. Then was acquaintance begun with miners' bathhouses. The remembrance of those rough board sheds, drafty, generally dirty and lighted by small oil lamps or often by the smoky pit lamps carried by the miners, is still vivid.

The water was heated on an old kitchen stove that also served to heat the building, and we bathed in round washtubs, standing up in them and using strong laundry soap. We had to commence with the top of our heads, and the strong lye soap suds from the shampoo would get into our eyes and blind us. By the time our knees were reached, the water was some dirty. Our backs generally remained shady unless some kind buddy lent a helping hand, and then he often took advantage of our innocence and used a broom or scrubbing brush. When bathing was finished, we dumped the water through a wooden trough out onto the ground and let the next man have our tub. If he was fastidious, he rinsed it out with hot water before bathing—but each man for himself. After getting out of the tub, one would get his feet all dirty again on the floor.

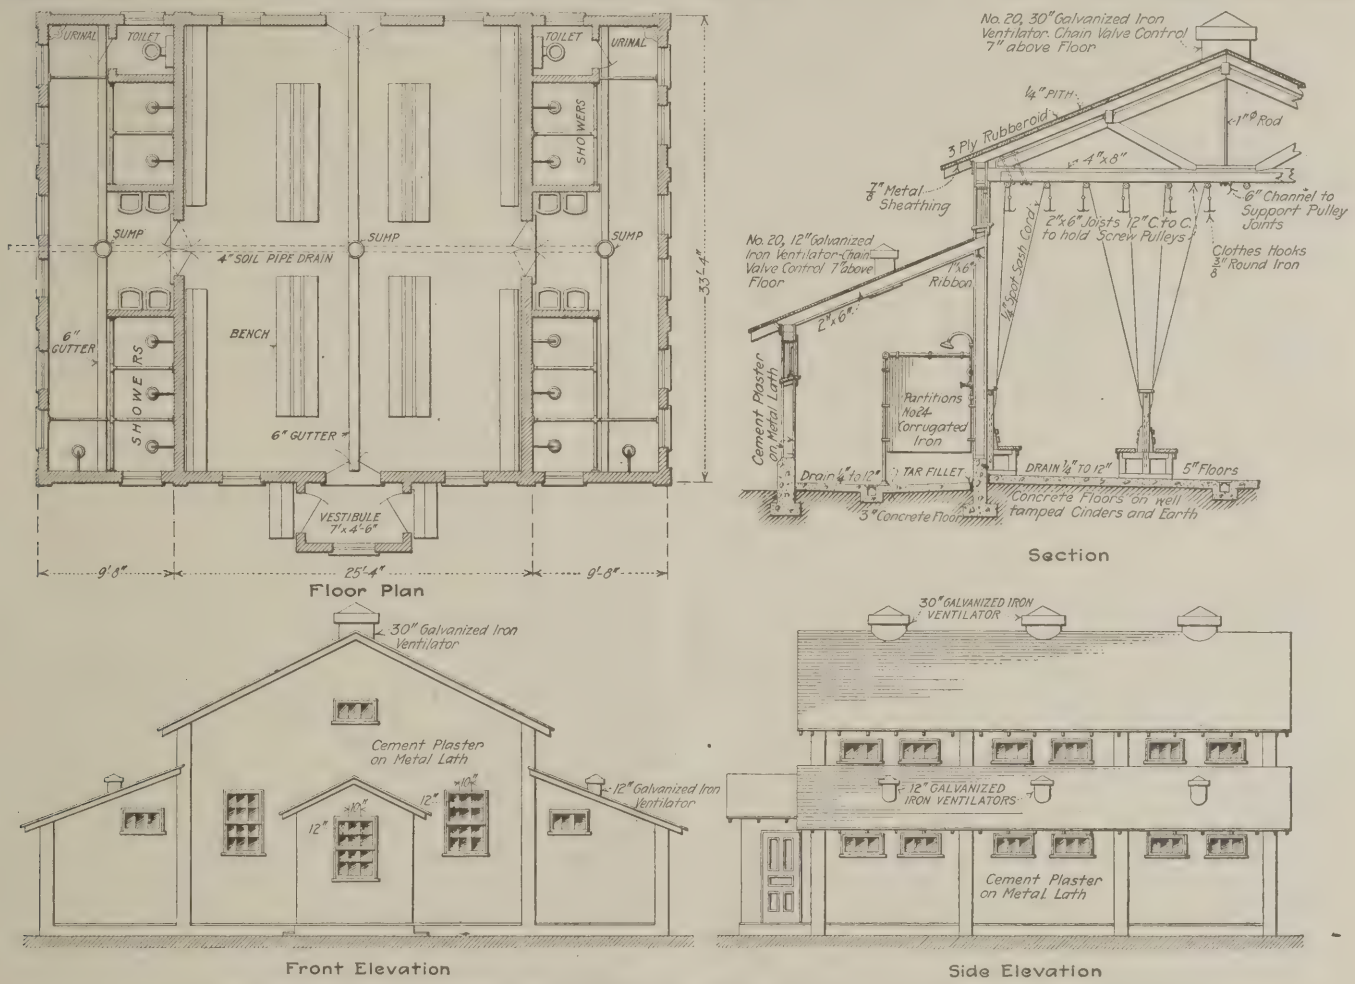
Looking back on it all, it does not appear strange that some miners feared the ordeal of washing their back and legs above the knees, because of the belief that it made them weak.

There were unauthenticated rumors of metal mines somewhere in the state that had steam-heated washhouses with porcelain bathtubs, lockers, etc., but though we longed for them, never a one did we see. When the time came that partly through demands of the men and partly because of the desire of operators to make working and living conditions for the men and their families as attractive and hygienic as possible, we were called upon to design and erect bathhouses, the task was undertaken with considerable appreciation of what it would mean to the employees.

Unfortunately, plans and descriptions of bathhouses were few and meager. There had appeared in the col-

umns of *Coal Age* from time to time descriptions of the elaborate bathhouses in France, Germany and Belgium, and one or two American installations. The cost of structures as built in European countries would be prohibitive in the mountain states, but by way of comparison a table was made up showing the main features (see Table I). The Utah Fuel Co. adopted a standard design for its main bathhouses, and in 1917 built three of them at an average cost per man of about $33.

There are many conditions to be met in the design of such structures. The location is the first question to be solved, for upon it depends many features of design. In the mountains space for buildings is often quite limited, and as it is essential to have the bathhouses close to the mine mouths, both because of convenience and to protect men in cold weather when they come out of the warm mines, the shape of the building must be made to conform to the topography of the country.



Usually the building must be long and comparatively narrow. In the design adopted, 45 ft. was about as wide as ground space in canyons usually permits. The building should either be located near the lamp- and checkhouses, or be combined with them. By so doing it is often possible to effect saving in attention.

The powder distributing magazine should also be located at a convenient distance from the bathhouse. Furthermore, the landing or stopping stations for man trips must be considered when deciding on a location. Fortunate indeed is the mine at which all these considerations can be satisfactorily taken care of and still have the bathhouse close enough to the power house to be supplied with steam heat and hot water without long, wasteful pipe lines.

Being thus of necessity close to the mine mouth, the building must be practically fireproof. With common brick at $25 per M., cement at $4 to $4.50 per barrel, sand $3 per yard, steel almost worth its weight in gold and wages from $6 to $8 per 8-hour day, it takes some figuring to prevent the costs running up. The design adopted was a wood frame building covered on the sides with expanded metal lathing and cement mortar, the outside wall being back-plastered. This gives an air space which aids in the heating and prevents condensation of moisture.

One of the buildings was given a pebble-dash surfacing on the outside, using fine coke breeze for pebbles. The result was a light grayish green color very pleasing to the eye. Exposed woodwork was painted brown. The other two buildings were smooth-finished. With such finish, shrinkage cracks can be easily treated. The inside walls were smooth-finish, and after thorough drying were given a rich cement wash to fill all hair cracks and render walls more nearly impervious to water. Renovation can readily be accomplished by use of suitable cold-water paints.

For roofing, galvanized corrugated iron, or some kind of asbestos prepared roofing, laid on ship lap, makes a suitable cover. Exposed iron roofing invites condensation with consequent drippings. The buildings were designed on the unit basis, so that if expansion is desired, a panel at a time can be added without undue expense and without change of plans or symmetry.

PLAN, CROSS-SECTION, SIDE AND END ELEVATIONS OF A TYPICAL MINE BATHHOUSE

Not only must the size be kept down to conform to and conserve available ground space, but the cost must be thoroughly considered; and as such buildings are essentially one-story structures, the larger the ground space the greater the cost. For this reason hangers for clothes were adopted instead of the locker system. Of great importance, also, is the sanitary question. Lockers permit the spread of vermin and disease, and Pulley hangers and ropes with means of fastening to the benches were furnished by the company, but the men are required to furnish their own locks, towels and soap. With hangers, the danger of fires is obviated to a considerable extent.

Ventilation must be carefully considered, for it must be adequate, yet without drafts. With this in mind the windows were placed high; chimney ventilators were

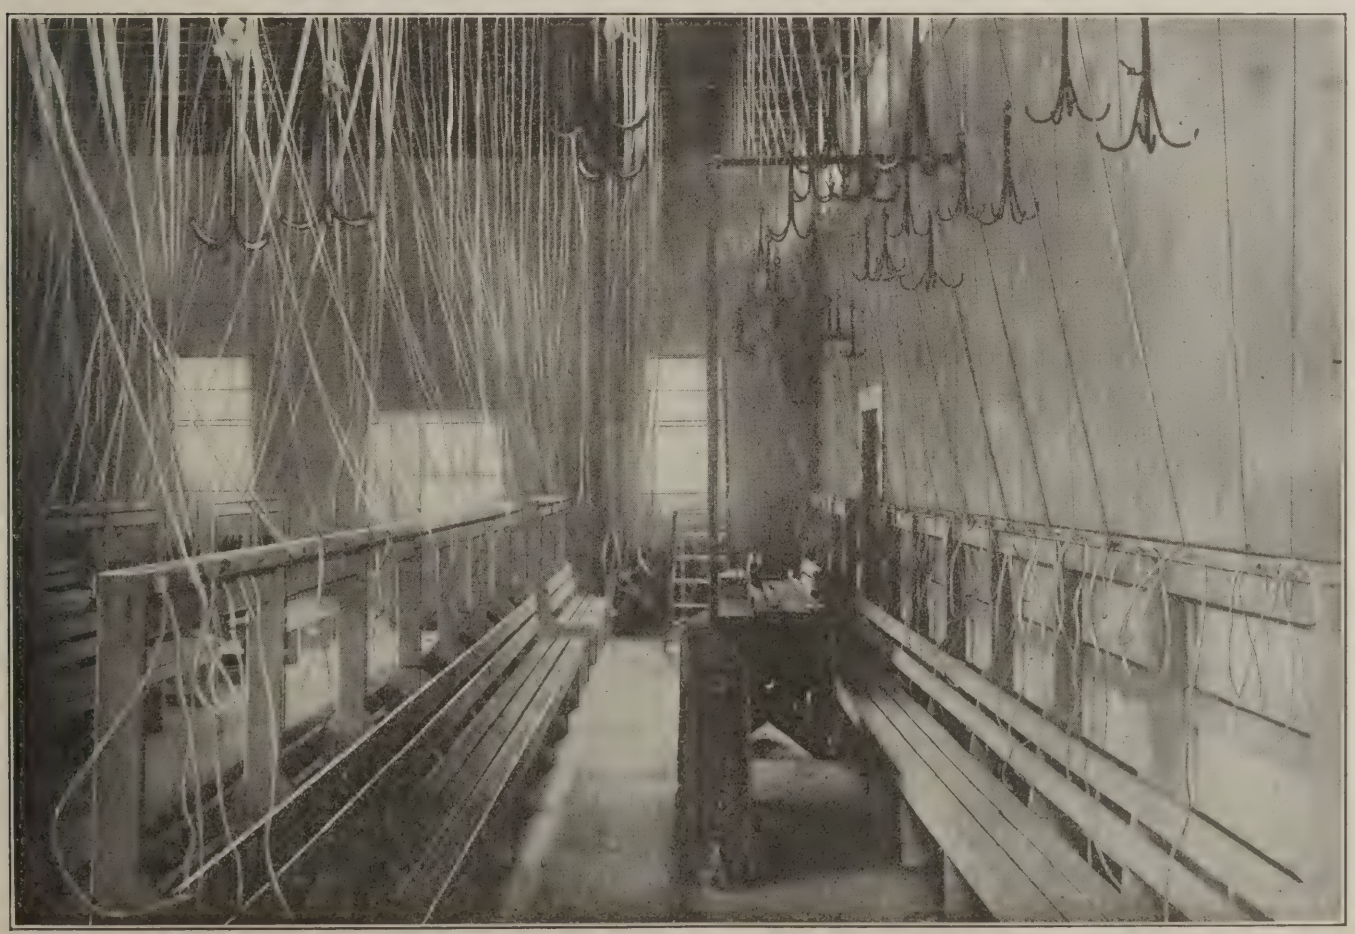
give an unpleasant odor to the dressing room, whereas by suspending clothes near the ventilators in the roof, odor is eliminated and opportunity is given to thoroughly dry and air them. If sufficient space is allowed between hangers there is no danger from spread of vermin. It was found that at least 30 in. should be allowed between hangers, and rows should be staggered. put on the peak of the roof, with valves for opening and closing them. Vestibuled entrances with side doors and swinging doors, giving entrance to the main building, were adopted.



Steam heating was employed, the pipes being placed where possible overhead and away from casual contact by men. It is also desirable to place guards around

THIS MINE WASHROOM CONTAINS MANY FACILITIES FOR A GOOD SCRUB

Typical Views Inside One of the Modern Bathhouses Erected by the Utah Fuel Co. for the Use of Its Employees

CHANGEROOM IN THE BATHHOUSE—NOTE THE HOOKS FOR CLOTHES

pipes and radiators to prevent the men from being burned. There need be little hesitation over a decision as to whether tubs or showers should be adopted, for apparently the arguments of sanitation, economy of time and water are all in favor of showers.

The heating of the water was done by live steam with pressure regulated to suit the water pressure. The water is heated at the showers by special mixers which are so made that it is impossible to scald by steam. There are several good mixers on the market. When the pressure of steam for room heating is different than the pressure required for water heating, two steam lines must be used, each equipped with pressure regulators. To prevent waste of steam in the heating plant, steam traps must be provided or a return system to the boilers used. When economy of water is a requisite steam mix showers cannot always be used, but water must be heated by special heaters and showers equipped with automatic closing valves. These, however, are inconvenient because but one hand can be used in bathing and the water temperature is not easily regulated.

The floors in the change- and washrooms are of concrete. The foundation walls for the sides of the building and partitions are concrete for about 2 ft. above the floor. All floors drain to a central trench covered by wood gratings, and the drainage is properly trapped and led to cesspools or septic tanks. It may be desirable to place grease traps in these drains in some instances. Hose connections are provided at several places so that all floors, walls and benches can be easily and thoroughly washed. Using hangers for clothes instead of lockers makes this cleansing easier and more thorough.

Ample Room for Change of Clothes

The changeroom must be designed so as to allow ample room for dressing and for the passage of men into and out of the bathrooms and building. With this in view, the bathrooms were placed on each side of the changeroom with swinging doors in the middle of the partition. An aisle between ends of benches was left opposite these doors.

As shown in the plans, the washrooms are built all along the sides and are equipped with showers, washbowls, urinals and closets (the latter inclosed). The ventilation for these washrooms was kept separate from the main building, and efforts were made to keep the moist air in them from entering the changerooms. The entire building should have plenty of natural light. Light, cleanliness and health form a trinity indispensable to efficiency and happiness. The windows should be placed as high as possible. In the plans shown the windows in the washroom are hinged at the bottom.

The first design contemplated partitions between showers, but these were not put in as it was decided it was more convenient and efficient without them. Experience, as shown by compiled statistics, indicates that one shower per 12 men is sufficient. It is well to have plenty of space in the washroom, so that men may dry themselves and walk to the changeroom without being again wet from the showers. This can be accomplished by a partition when space is at a premium, or by inclosing the showers or by giving ample width to the room.

A charge of 50c. per man per month is made for the use of the bathhouse. This is hardly sufficient to pay the janitor's wages, let alone amortization, maintenance, interest, taxes, insurance, water, heat and light, but the company considers it a good investment if it lends to the health and happiness of the community.

How do the men take to the bathhouses, do you ask? Well, you know how a gang of kids act when they go down to the swimming hole for the first time in the spring. They all stand around waiting until some boy takes the first dive, and coming up to the surface, yells, "Comonin youse fellers, the water's fine." Then the rest all make haste to follow suit. So with our miners; they were a little backward at first, but now they often refuse to work in a mine which has no bathhouse, and applications have been received from outsiders for privilege to use them. The company now has bathing facilities at all its mines, and these will be enlarged as the demands grow.

Psychology of Efficiency and Fatigue

The director of the psychological laboratory at Cambridge University, England—Dr. Charles S. Meyers—is the author of a little book reecntly published entitled "Present Day Applications of Psychology." In commenting on this book, *The Colliery Guardian* states that of late years much attention has been given to the analysis of the factors governing industrial efficiency, as measured by muscular and mental work. By means of the ergograph, a muscular work curve can be obtained and certain principles regarding fatigue and recovery have thus been established.

The author illustrates the application of these principles by examining the case of 500 shovelers, employed in moving coal. Experiment soon proved that efficiency depended upon the use of a shovel weighing with its load about 21 lb. Thus, by adjusting the weight of the shovel to the material shoveled, the following astonishing results were obtained: (1) The average amount shoveled per day rose by nearly 270 per cent., or from 16 to 59 tons per man. (2) One hundred and fifty men could now perform what 500 men had previously accomplished. (3) The average earnings of the shovelers increased by 60 per cent. (4) The cost to the management was reduced by 50 per cent. (5) There was no evidence of increased fatigue of the men.

Dr. Meyers also examined the relation between the work curve and the curve of frequency of accidents; this question has often arisen in connection with the discussion of colliery accidents, and no marked periodicity has in this case been established. The statement is made, however, that in certain accident curves the number of accidents increases inversely as the output. The influence of rest periods, also, is somewhat complex and experiment seems to point to the fact that for every kind of work there is a most favorable rest period—that is, a pause in which the various factors so operate as to produce a maximum amount of work after the pause. Long unbroken spells of work are economically unsound, and systematic rest pauses lead to a great improvement in the quantity and quality of the work produced.

Coal Tipple and Washery at Lehigh, Mont.

By E. P. STEWART
Chicago, Ill.

SYNOPSIS — *The apparatus here described is designed to thoroughly clean and prepare locomotive fuel. A unique feature is the provision of efficient drying equipment, so that the washed coal may be shipped in open cars without danger of freezing.*

THE Cottonwood Coal Co. has a large coal property in Fergus County, Montana. The Lehigh Shaft No. 1, at which point the plant to be described was built, is located in the westerly end of the Judith Basin. While the field is extensive, the coal obtainable contains many impurities, such as slate, heavy bone and sulphur. Fully aware of this, the Cottonwood Coal Co., when it decided to open this field, determined to provide thorough and efficient facilities for cleaning the coal so that the best locomotive fuel possible might be produced, as the entire output is taken by the Great Northern Ry. Design and construction of the plant were accordingly intrusted to the Roberts & Schaefer Co., of Chicago.

The plant and process herein described were adopted in order to secure a coal as free from impurities as possible, and of a maximum size of 5 in.—suitable for hand-firing in locomotives.

The mine cars, at the shaft bottom, are delivered automatically to the self-dumping cages. The track grades on entering the shaft bottom are such that the loaded cars run by gravity into the caging device, which permits of only one car at a time being delivered to the cages. This dispenses with labor, delay and annoyance caused by a car getting in the sump when a car or a trip accidentally becomes uncontrollable.

The handling of the mine-run coal, preparatory to treatment of the various sizes, is accomplished as follows: The coal, after being weighed in the mine, is hoisted to the top of the tipple by means of four self-dumping cages. The pit cars discharge into a large steel hopper, from which coal is fed out uniformly by means of apron feeders onto two duplicate sets of shaker screens. The coal is accurately sized on these screens into lump over 5-in. perforations, egg through 5-in. and over 2½-in. perforations, and screenings passing through 2½-in. perforations. The lump coal is delivered to a picking table, as is also the egg size, while the screenings are deflected to the coal washery for treatment.

A method of coal handling was decided upon whereby the larger sizes in the mine-run are thoroughly picked by hand, and all rock and heavy bone eliminated as nearly as possible. The finer sizes or screenings are washed in a coal washery. All sizes after they are cleaned, dried and properly treated are finally collected in a shipping bin and transported to the various coaling stations on the line of the Great Northern Railway.

The plant is designed for a maximum, eventual output of 3500 tons per day. The present mine output is between 1000 and 1200 tons daily. Rock and bone rejected approximates 12 per cent. of the mine output. The Lehigh plant is of considerable general interest through its features for efficiently removing rock and bone from coarse as well as the finer sizes; its ample and well arranged facilities for accomplishing these results by human and mechanical means, and particularly for its facilities for thoroughly drying the finer sizes, thus removing entirely any tendency of coal to freeze in railroad cars during severe winter weather with consequent loss of time and embarrassment to railroad op-

VIEW OF THE PICKERS AT WORK IN THE WELL-LIGHTED TIPPLE BUILLDING

eration. Special precautions also had to be observed in properly housing the plant and equipment to secure the comfort and protection of the operatives.

The slack coal coming from the screens is approximately 45 per cent. of the mine output. The mine shaft is 208 ft. deep from ground surface to bottom of coal, and has five compartments—four for cages and one for pipes. A lengthy description of this shaft will not be entered into here, as the subject was covered by J. W. Powell in his article in *Coal Age* for Mar. 11, 1916. The total hoist is approximately 280 feet.

Hand-picking of the lump and egg is accomplished in a large, comfortable, well lighted room in the tipple structure. All rock picked out is deposited in chutes which lead to a large rock-and-refuse bin in the tipple below the picking-room floor. Bone coal, as picked, is deposited in similar chutes which lead to a conveyor that transports this material to a crusher. The crusher reduces the bone to a maximum size of 2½ in. and delivers the crushed material to the same equipment that conveys the screenings to the washer. It will thus be seen that the washer not only handles and cleans the screenings, but recovers combustible material as well from the bone picked from the tables. The picked egg coal is delivered by the table to a conveyor leading to the final shipping bin. The lump coal is also delivered to this conveyor, but is first crushed to a maximum size of 5 in. by a Jeffrey single-roll crusher.

The tipple is equipped with local trade facilities so that miners and the townspeople may always have a supply of cleaned coal available. This coal, when required, is conveyed from either lump or egg picking table to a bin in the tipple, from which it is drawn out into wagons.

The operation of the coal washer proper is as follows: The screenings, together with the crushed bone, is conveyed to a large storage bin in the plant, from which it is fed out uniformly by means of reciprocating feeders into three Stewart jigs. These jigs remove the slate, rock and heavy bone and deliver the clean, washed product directly to the screening and drying apparatus. The refuse or reject material is elevated and either discharged into a refuse conveyor leading to the rock bin in the tipple above referred to, or into an Elmore type of rewashing jig. When this latter jig is employed, the recovered bone from the refuse is delivered into the stream of washed coal and water from the Stewart jigs and the final refuse into the conveyor leading to the rock bin in the tipple.

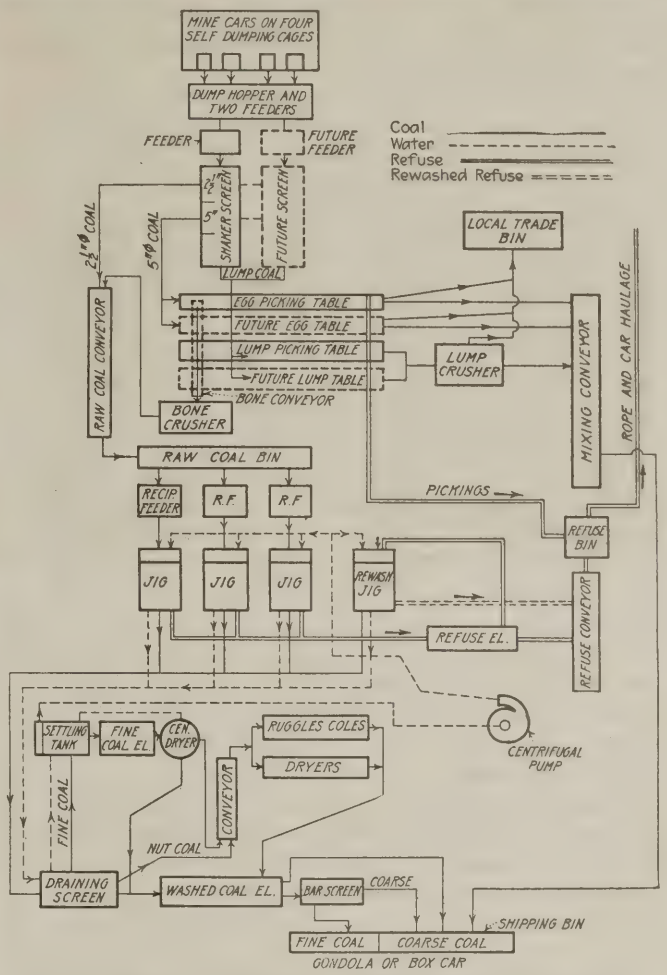
The jigs and washing apparatus are contained in a well lighted and comfortable room set aside in the plant for the purpose, and all equipment is readily accessible and adjustable.

Economical Water-Circulating System

The water-circulating system is that commonly employed in Stewart-type washers and is quite economical in fresh-water requirements. The circulation of the main volume of water is continuous. The water overflows the jigs with the washed coal into a sluice leading to a settling tank. The water in turn overflows the settling tank into a pump tank, from which it is pumped at the rate of 3000 gal. per minute into a supply tank immediately in rear of the jigs. Water flows from this latter tank periodically into the jigs and jig tanks and thence, as first described, into the washed coal sluice with the clean coal. The only fresh water required to renew loss is that actually absorbed by the washed coal and refuse in the washing process.

The method employed in drying the coal and preparing it for shipment is unique. It is desirable that washed coal be freed entirely from surplus moisture at all times and that in the severe winter weather it be thoroughly dried to prevent freezing. The process adopted is as follows: Washed coal and water flows from the jigs first to a revolving screen with a jacket having ¾-in. perforations. The fine coal, together with the water from this screen, is sluiced to a large settling tank wherein the coal has an opportunity to settle. It

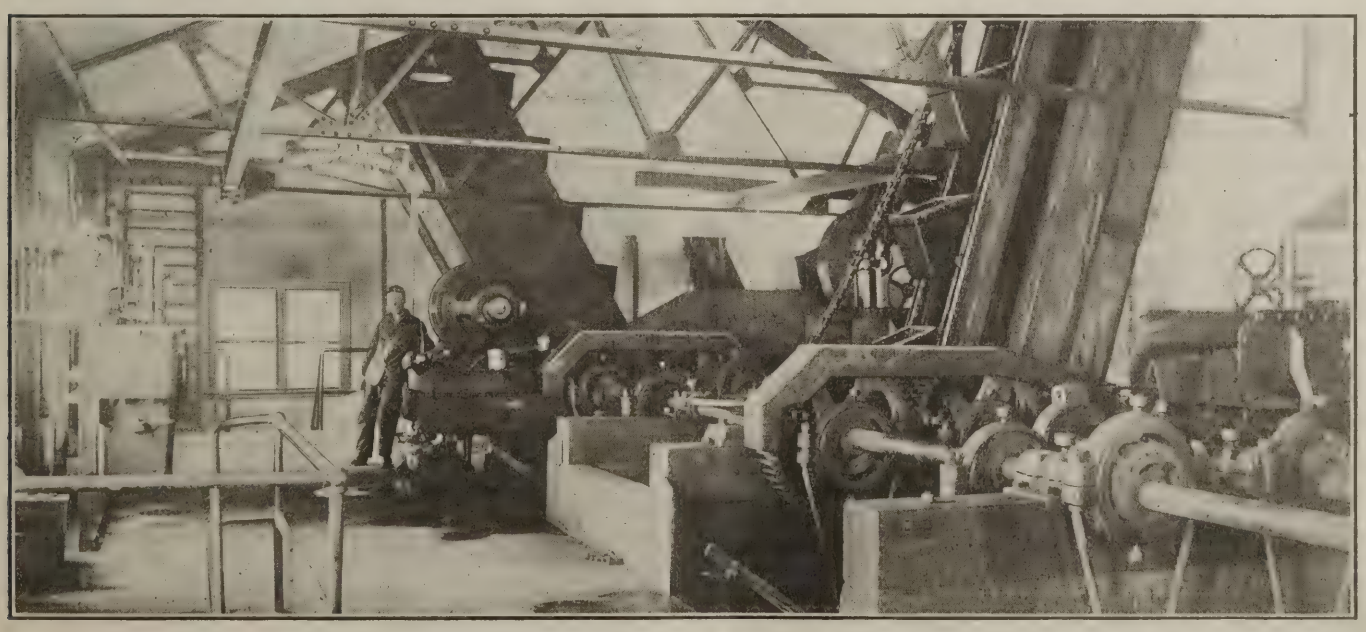
is then elevated from this tank and delivered to a centrifugal dryer. This machine operates at a high speed, and the coal is freed entirely of surplus moisture by centrifugal force. This dried coal, together with the oversize or pea coal from the revolving screen, is collected in a suitable hopper and elevated to the shipping bin. At the top of the shipping bin chutes are so arranged that crushed lump, egg and washed screenings are thoroughly mixed in the original proportions as mined, minus the rock and bone which have been rejected by the cleaning process. This assures a superior railroad fuel and for most months of the year a sufficiently dry product.



In extreme weather the pea size from the revolving screen, together with coal from the centrifugal dryer, is collected in a conveyor and delivered to two large Ruggles-Coles furnace dryers. These machines through the proper employment of heat thoroughly dry the coal and return it to the plant even dryer than that originally mined. After leaving the Ruggles-Coles dryers the coal is delivered to the elevator described above, and elevated to the shipping bin. It will be noted that use of the Ruggles-Coles drying system is entirely optional, depending wholly on weather and shipping conditions.

The washed coal is all ordinarily mixed with the cleaned egg and crushed lump, but at times it is desirable to ship some washed slack. A large bin adjacent to the shipping bin was built to contain this slack, which is obtained by discharging washed coal over a bar screen located above the bin.

The cleaned product is ordinarily loaded out from the shipping bin into gondola cars, but a box-car loader is installed which permits occasional loading of box cars.



As previously mentioned, rock as picked from the tables in the tipple is discharged through chutes into a rock bin. This bin also receives the refuse material such as rock, heavy bone and sulphur rejected by the washer. This waste product is all deposited in a large valley about a quarter of a mile from the plant. A rope haulage and large car transports the refuse to the edge of the valley, from which point the material is distributed by an aërial tramway system.

It will be noticed from the illustrations that the entire plant is fireproof and of permanent construction. All tanks and equipment supports are concrete and all other structures of steel. Housing consists of corrugated

FLOW SHEET, SHOWING OPERATION OF WASHERY

metal on outside and asbestos mill board on the inside surfaces. All equipment is electrically operated and all units of the plant are carefully arranged with a view to economy in design and easy accessibility.

PART VIEW OF THE INTERIOR OF THE WASHERY BUILDING, SHOWING CONVEYING MACHINERY

Fusibility of West Virginia Coal Ash*

By WALTER A. SELVIG

Chemical Laboratory, U. S. Bureau of Mines, Pittsburgh, Penn.

SYNOPSIS—*Method of preparing ash for fusion tests and determining initial softening temperature and interval of fusion. A tabulation of tests on West Virginia coals is included.*

INFORMATION concerning the fusibility of coal ash has become of considerable interest to the consumer of coal during the last few years, principally in connection with the troublesome formation of clinker which results from the melting of the ash constituents of the coal when subjected to heat.

The growing interest for such data has led the Bureau of Mines to make a general survey of the "fusing" or "softening" temperatures of the ash from well known American coals. It is hoped that this information when used together with the large number of coal analyses made available by the publications of the Bureau of Mines[1] will be of help to the consumer of coal in comparing the different coals and in the selection of the coal best adapted for his purpose.

This paper gives the results obtained for West Virginia coals, among which are found some of the purest fuels of the country.

The method employed for the fusibility tests was the standard gas furnace method[2] of the bureau. In order better to interpret the results given in the table of fusibility this method is briefly summarized here.

Preparation of Cones

The coal samples are ground to 60 mesh, with crusher, rolls and ball mill. This 60-mesh material is then placed in shallow fireclay roasting dishes and completely ashed in a muffle furnace at a temperature of 800 deg. C. to 900 deg. C.

The resulting ash is ground in an agate mortar to pass a 200-mesh sieve. To make sure that the coal has been completely ashed, the ash after grinding is placed in fused silica capsules and ignited at 800 deg. C. for two hours, a current of oxygen gas passing through the furnace during the ignition period. This ignition is made to insure complete and uniform oxidation of the ash.

A portion of the ash is transferred to an agate mortar, moistened with a 10 per cent. dextrin solution and worked into a plastic mass with a spatula. The ash is then molded into solid triangular pyramids ¾ inch high and ¼ inch wide at the side of the base. These cones are removed from the brass cone mold, dried and mounted in a vertical position in a refractory base made up of a mixture of two parts of kaolin to one part of calcined alumina. Usually five cones are mounted in the same base. The base with the cones is dried carefully over the hot plate until all water is driven off, then the dextrin is burned out of the cones by igniting the mounted cones in a muffle furnace at a dull red heat, after which the cones are ready for use.

Description and Operation of Furnace

The furnace used was the No. 3 melter's furnace (Fig. 1) of the American Gas Furnace Co., natural gas and air pressure of from 2 to 3 pounds to the square inch being used. The cones, supported by a suitable mounting, are placed within a covered fire-clay crucible in the furnace. A 2-in. hole is drilled through the furnace jacket and fire-clay crucible for observation purposes, a fused silica tube carrying a thin glass window being placed in the observation hole. At right angles to the observation hole a ¼-in. hole is drilled through the furnace and crucible. Through this hole a platinum-rhodium thermo-couple, protected by a glazed porcelain tube, is inserted. By proper adjustment of the gas and air a reducing atmosphere is maintained within the furnace, this being accomplished by using the minimum amount of air necessary to attain the desired temperature. Under these conditions, the iron in the ash is

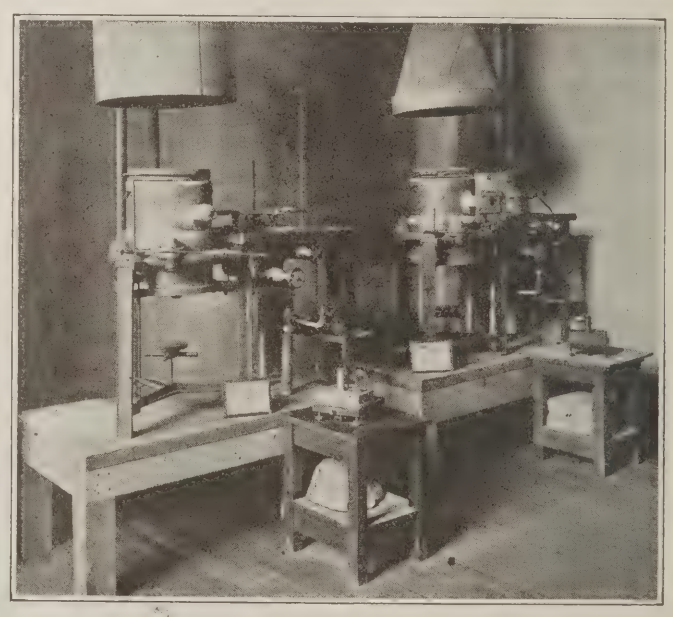


FIG. 1. NO. 3 MELTER'S FURNACE AND ACCESSORIES

reduced to the ferrous state, which condition gives the lowest melting points and therefore gives the lowest temperature at which clinkering may result. The temperature is gradually increased to 800 deg. C., when the rate is slowed down to not less than 5 deg. C. nor more than 10 deg. C. per minute, this rate being maintained until the end of the test, when a maximum temperature of 1500 deg. C., or 2732 deg. F., is attained.

In some instances with coal ash of an especially refractory nature the cones which did not fuse at the

Fieldner, A. C., and others: Analyses of mine and car samples collected in the fiscal years 1913 to 1916: Bull. 123, Bureau of Mines, 1917, 456 pp.

[2]For detailed description of this method and discussion of the influence of various factors on the fusibility of coal ash see Fieldner, A. C.; Hall, A. E., and Feild, A. L.: The fusibility of coal ash: Bull. 129, Bureau of Mines, 1918. 146 pp. (In press.)

highest temperature attained in the gas furnace, were further heated in a molybdenum wire resistance furnace[3] in an atmosphere of hydrogen gas. Under these conditions temperatures as high as 3010 deg. F. and in some instances slightly higher were attained. However, a coal whose ash fuses above 2730 deg. F. should give very little trouble due to clinker formation.

The temperature readings taken were:

(1) *The initial deformation temperature.* The temperature at which the first rounding or bending of the apex of the cone takes place as shown in cone 1 of Fig. 2.

(2) *The softening temperature.* The temperature at which the cone has fused down to a spherical lump as shown in cones 2 and 3 of Fig. 2.

Only the average softening temperature is reported, together with the softening interval, which is the difference in degrees between the softening temperature and the initial deformation temperature.

Interpretation of Fusibility Table

According to the West Virginia Geological Survey there are 102 known coal beds in West Virginia, of which 52 are minable. The table contains samples representing nearly one-half of these minable beds, those listed being among the most important in the state.

The various beds are arranged according to their geological succession, from information supplied by courtesy of the West Virginia Geological Survey together with information taken from the Keystone Coal Catalog,[4] the uppermost coal beds being listed first.

It will be noted that the uppermost series given is the Monongahela series, there being no samples representing the overlying Dunkard series, which top out the highest beds in the Appalachian field; however, these coals are of very little commercial importance at the present time.

The results for each mine show the lowest softening temperature, the highest softening temperature and the average for the mine. The softening interval is tabulated in the same manner. In addition to these values the per cent ash and sulphur, on the dry coal basis, is given.

The average values given for each bed provide a means of comparison of the different coals; however, of course, the average values are averages of the mines which are listed under each bed, consequently the greater the number of mines sampled the more representative the values are of the bed. In some instances only a few mines are listed under the bed. In these cases the average values given are only representative of the mines sampled, and do not constitute a fair average of the bed. Beds such as the Pittsburgh, Sewell, Beckley and Pocahontas No. 3, from which a large number of samples have been tested and the softening temperature values for the various mines are uniform, the average values given may be taken as representative of the bed.

It will be noted that the softening interval values given in the table vary to a considerable extent. These values, as already explained, give the number of degrees interval between the temperature at which the tip of the cone fuses or bends and the temperature at which the cone has fused down to a spherical lump, which temperature is recorded as the softening temperature. The point at which the tip first fuses or bends is rather difficult to obtain exactly on account of the phenomena of warping and shrinking of the cones which sometimes result when the cones are subjected to heat. The softening interval is interesting mainly as a study of the viscosity of the melting ash. The softening temperature values given are the values which are used in comparing the different coals. This is the most definite and easiest point to check in the tests.

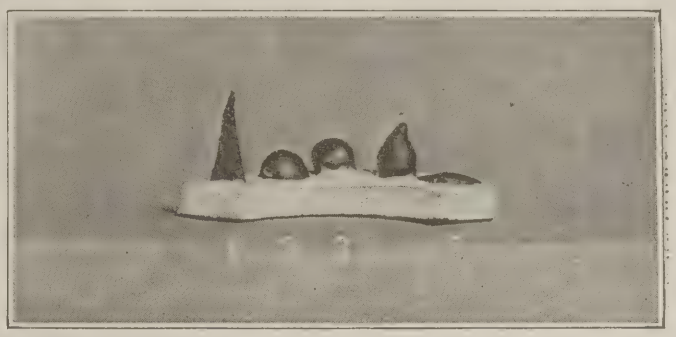

FIG. 2. TYPICAL FORMS OF CONES FUSED IN THE NO. 3 MELTER'S FURNACE

Under the Monongahela series the Sewickley, Redstone and Pittsburgh beds are listed. Not sufficient mines are represented to give representative average values for the Sewickley and Redstone beds. The Pittsburgh bed, which is the most important coal bed in the northern part of West Virginia and contains one of the most valuable fuels of the country, is fairly well represented. This bed varies considerably as to sulphur content in different regions. It will be noted, however, that the softening temperatures as given are fairly uniform, but are lower than many of the other beds listed.

Discussion of Coal Beds Tested

The mines listed under the Conemaugh series are all coal banks from the Mahoning bed, which is of no commercial value but is mined for local use. The average softening temperature from these coal banks is practically the same as that of the Pittsburgh bed.

In the Allegheny series the lower Kittanning or No. 5 Block bed is a very important coal. This bed varies from a high volatile coal in the southwestern half of the state through an ordinary bituminous type of coal in Randolph and Barbour counties to a semi-bituminous coal in the North Potomac basin.[5] As might be expected from a coal varying so much in composition, the values given for this bed vary over a wide range, but no doubt the mines listed give representative values for their immediate districts.

The coals listed under the Kanawha group of the Pottsville series are coals giving ash having a uniformly high fusing temperature. The No. 2 Gas is the most important and valuable bed of this group and is widely known commercially. This bed as well as others of this group contains coals giving ash having a high fusing temperature.

NOTE—A plus sign (+) placed before a given value denotes that the true value is above that indicated. An asterisk (*) placed before a given value denotes that the values given are those actually observed; however, a temperature high enough to fuse all of the samples was not attained, therefore the true value might be either greater or less than the indicated value.

The New River group of the Pottsville series contains some of the best known coals of the country, coals having a low ash and sulphur content, also giving an ash with a high fusing temperature.

The Sewell bed, which is the most important of the New River group, is very well represented in the table. The mines tested give a very uniform fusibility of ash value, and the average value for the bed is good. This coal, which is semi-bituminous in character, is one of the famous steam-producing coals of the country and at the present time is the most extensively developed of the New River coals.

The Beckley bed, which is a very important member of the semi-bituminous coals of the New River group, shows some remarkably high fusibility values. The ash from this coal is of a specially refractory nature and this bed gives fusibility values higher than any other of the beds of West Virginia that were tested. This coal should prove of interest to consumers demanding a high grade coal giving an ash of an exceptionally high fusibility.

The last group listed and the oldest and lowermost of the West Virginia coals is the Pocahontas group, which contains the famous Pocahontas No. 3 bed of Mercer and McDowell counties. This seam produces the well known Pocahontas semi-bituminous coal, which is one of the purest coals of the country and is being used extensively as a steaming and coking coal. The average values given for this bed represent 246 samples, so they should be considered to be representative of this celebrated coal.

As is seen, the figures representing the different mines are very uniform. Although the average softening temperature of this bed is not as high as some of the others, especially the Beckley bed, it is uniformly high and little trouble should therefore be experienced because of clinkering.

Grateful acknowledgment is made to A. C. Fieldner, chemist, formerly of the Pittsburgh Station of the Bureau of Mines, under whose supervision most of the tests were made. Many of the tests were made by Messrs. A. E. Hall, V. C. Allison, C. R. Locke, C. S. Purcell, W. C. Ratliff and O. C. Brown, all of the chemical laboratory of the Bureau of Mines.

Science and Research in Coal Mining

By GEORGE W. HARRIS
Editorial Staff *Coal Age*

SCIENCE in coal mining is an old expression with a new significance. Research work along technical lines has been encouraged and fostered by the Consolidation Coal Co. for years. Consulting Engineer Frank Haas has been guiding the company's able assistants of the laboratory and engineering forces in their efforts to develop something practical. No expense has been spared, and it was mainly through the patient coöperation of these technical workers in the field of science that such satisfactory results have been achieved—of practical benefit to operator and miner alike. Notable among these achievements is the application of gas analysis to the scientific control of mine ventilation; the idea of the gas test being the immediate safety of the miner and the mines.

LABORATORY OF CONSOLIDATION COAL CO. AT FAIRMONT, W. VA.

This method of gas control is peculiar to the Consolidation Coal Co., and the same system is in vogue in all the fields in which coal is mined by this company. Conceived by Mr. Haas, the method has been fostered by him for many years; all field and laboratory reports on gas and ventilation details are submitted to him, and his judgment dictates the policy of the company in such matters. The ventilation problems differ somewhat in the various fields. For example, the situation in the Fairmont-Clarksburg region of West Virginia is the most critical, as here gas is met with in appreciable quantities—methane or firedamp especially being present in some sections. The numerous natural gas wells throughout this field also tend to complicate matters materially. On the other hand, in the Georges Creek region in Maryland, blackdamp and mine fires claim especial attention.

The Consolidation mines are classified, as regards the gas test, into three groups. Those that yield no gas, moderate gas producers, and mines that make more than an average amount of gas. A regular force of men is detailed to collect samples of gas in the mines and to look after the ventilation. Such men also act as a first-aid corps and as fire fighters; they are thoroughly experienced in the use of oxygen apparatus and so on. However, it is only occasionally that they are called upon for fire or first-aid service. Nevertheless, at least five men are always immediately available should the occasion come up for their use. All Consolidation mines are tested once a month; those of the second or medium class once a week, and mines which produce more than an average amount of gas are tested daily.

The field gas-testing forces report to Mr. Haas daily, so that no critical situation fails to be brought quickly to his attention and his judgment is final in all such matters. The field forces have no authority in themselves, but tney are independent of the operating department. However, being on the ground they naturally confer with local officials. When changes in ventilation are necessary they are promptly made. There is practically always sufficient coöperation between the two departments so that there is no difficulty to get the results desired. If at any time a conflict of opinion should occur, the matter is settled by a higher authority—Mr. Haas or a division manager. There is no friction. The percentage of gas is kept strictly to less than five-tenths of one per cent., and quick action is secured in critical cases. Also 100 per cent. humidity is aimed at to keep down the dust in the mines.

The corps taking gas samples are entirely separate from the ordinary inspection and safety men. Each man on the corps is made capable of handling the ventilation proposition in the field; each man is equally responsible, but naturally the oldest man in the service takes the lead. Corps are interchanged from time to time in each division. Also men are brought from other divisions for a limited time so that they may learn something about conditions different from those encountered in their own field. The result of this system is the decidedly lessened tendency to explosions and fires.

A person traveling about any of the fields in which the Consolidation operates can hardly fail to notice men going from mine to mine with their copper cans. Often about a dozen cans are carried at a time. Each can holds something over a quart or a sufficient amount of gas for two or three analyses. On reaching a mine the cans are filled with water, and when a sample of mine air is to be taken the stopcock at each end of the can is opened—as the water runs out of one end the air enters the other. At this time the can is not necessarily placed in any special part of an entry—usually where a man would naturally hold it. Ordinarily the sample is taken in the moving air where the mixture is complete. When gob gases are to be tested it is a different matter, and the sample of air is taken close to the gob where there may be little or no ventilation.

In addition to the samples of gas considerable other information is obtained by the gas inspectors on their daily rounds, which is entered on the gas report. Continuous barometric readings have been taken by the Consolidation company for the last 15 years, and it has not been noticed that changes in barometer have an appreciable effect on the flow of gas in their mines. This is a matter about which doctors disagree. The evidence on this point by a company which operates a large number of mines in the four principal fields of the Appalachian coal basin is valuable. Furthermore, the observations cover a long period of time.

One of the large anthracite coal companies in Penn-

sylvania gives contrary evidence. This latter company notes carefully every change in the barometer at its main office. On a decided drop in barometric pressure, warnings are at once sent to all the company's mine foremen notifying them of the fact. Thus warned they watch for danger signs in their mine air. It is a matter of record with this anthracite company that practically all their mine explosions, for the time under observation, have occurred during falling barometer or at times of low barometric pressure. It may easily be that these apparently diverse opinions may not be antagonistic in the face of more complete details covering each case. The matter is considerably more than technically interesting, for it has an important practical bearing on mine operation. The Consolidation company takes the readings of an instrument on the top of its office building in Fairmont and assumes this barometric pressure to be correct for the whole Fairmont-Clarksburg field. This matter was investigated for several years before the plan noted was adopted.

By referring to the accompanying reproduction of the gas report sheet used by this company, it readily will be seen what information the gas inspection corps must secure. On this report illustrated, a cross (X) indicates information which must be obtained in the field; from these data the "Dew Point," "Relative Humidity" and "Gal. (of moisture) per 1000 C.F." (cu.ft.) are calculated in the office; the percentages of CO_2 (carbon dioxide) and CH_4 (methane) are determined in the laboratory. In further explanation of the report it should be added that gas samples are taken on the main intake and return; this gives the condition of the air for all splits collectively. In addition a sample is taken on the intake and return of each split; these samples are taken close to the main entries. Thus the exact condition of each portion of the mine is determined.

THE CONSOLIDATION COAL COMPANY, INC.

Ascertain and Note:—Speed of fan (r.p.m.) blowing or exhausting; putting steam into air or not; mine working or idle; total volume air entering mine and exhausting from mine; volume of CH_4 (methane) produced in 24 hours.

In the matter of temperatures, the outside temperature is taken before entering the mine and again on coming out. The main intake temperature and bulb readings are taken just inside the point where the air is humidified by exhaust steam (within 150 to 200 ft. inside) or at any point on the main intake between the point noted and the first split on the main headings. Suspended moisture is not indicated by the bulb.

In the laboratory two samples are taken from each can and the gas is analyzed by the Hesse method—a titration process which gives result within $\frac{1}{100}$ of one per cent. One of the gas samples taken is analyzed for CO_2 and the other one for CH_4. When a complete analysis of gas is desired, the Burrell apparatus is used. This latter method is employed in the case of special investigations and gives results for CO_2, O, CO, H, CH_4 C_2H_6 and heavy hydrocarbons. In its investigations, this company reports that it has never found any hydrogen in the mine air of its operations. The special investigations in which the Burrell method is used include analyses of gas in the case of mine fires, gob trouble, gas feeders, and so on. In the case of a mine fire, the mine is sealed off and pipes are placed in the stoppings so that samples of gas can be taken at intervals for analysis. The analyses of such samples show the condition of the mine air in the isolated section and are a reasonably safe indication of what is happening in the fire area. As long as any oxygen is found in the air, combustion can be supported and it would not be safe ordinarily to assume that the fire had died out.

In connection with mine fires and gas analysis there would seem to be a particularly profitable field in Illinois for the safety method employed by the Consolidation. In portions of this state the mines are quite gaseous and the coal contains more or less sulphur. Added to these conditions is the customary practice in many sections of not robbing any pillars. In mines where unsystematic or loose methods of mining are in vogue there have been many squeezes and much loss of coal. These are ideal conditions for just what has happened in many instances—gob fires. From this start, pillars have been fired and oftentimes serious loss of time and money have occurred before the mine could again resume operations. These conditions have been so familiar throughout many portions of the state as to breed contempt in some cases. It would seem that the larger companies at least in Illinois could to advantage adopt a system of gas analysis and inspection, which would practically insure their mines against ordinary fires. If a gob fire is taken in hand in its early stages little trouble should be experienced. Many of the mines in this territory are dry. Gob fires, dust and gas furnish ideal conditions for trouble.

In the Consolidation practice the complete gas reports are regularly handed to Mr. Haas, who thus keeps in close touch with ventilation conditions throughout the mines of his company. The ventilation is changed in individual mines from time to time as the tests of air are interpreted to show this necessity. The rate of flow of gas may increase or decrease in various parts of a mine or in the mine as a whole.

About the first of October a change from wet to dry condition of the mines generally occurs in West Virginia. As the temperature of the atmosphere de-

creases less moisture is carried into the mines and the dust tends to dry out. Now is the time to use extra precaution to see that the humidity of the mine air does not drop with the temperature. Most of the dust explosions occur in the winter.

When the percentage of methane (CH_4) closely approaches five-tenths of one per cent., the gas is further diluted to render mine conditions safe. Furthermore, the mine air is kept saturated with moisture as far as practicable and the reports usually indicate a humidity of nearly 100 per cent. in the mine air. When the degree of humidity drops, more moisture is turned into the workings—either the exhaust from a fan or other engine or by means of occasional sprinkling.

This company keeps records of the flow of gas in its mines in graphical form. Curves show conditions of gas flow of mines from year to year; being platted on a small scale, daily variations are not prominent. Monthly increase or decrease is well brought out, however, and much interesting data are presented. Some workings show a rapid and regular increase of gas flow from the time shipments of coal start at a plant until considerable development has been secured. After a time the curve has less fluctuation and then settles down to a steady and uniform flow for years. A vast amount of instructive information has been accumulated by Mr. Haas on gas control and mine ventilation.

Recently the company has opened a number of new mines which are planned to be big producers. These workings seem to have tapped a particularly gassy section and their development has been watched with the greatest care. Mine maps of these workings were tacked up on the walls of an office at headquarters; they were drawn to a scale sufficiently large to show all necessary details. In the early development stage the ventilation of the workings was most critical. The gas inspectors went to each and every working face each day, following the entire air current to investigate exact conditions. The inspectors reported at night at headquarters and the information was actually placed on the mine map. The exact condition of the ventilation was shown by a thread which was carried from point to point around pins placed on the map at turns of the ventilation current. All brattice was marked and the map showed that every face was ventilated. The mine workings were extended daily from measurements of inspectors or engineers. If any face was shown ahead of ventilation the matter was investigated at once. This was done until the mine was opened up sufficiently to have conditions stabilized, after which the work was not carried out in such exact detail.

Most detail work carries with it a certain amount of drudgery, but the men on the gas corps have an unusual opportunity. They must have both technical and practical experience on this work. Often they are practical men trained in the technical line of their work by the head of the department. These men go to all parts of the company's mines in a region and at intervals they are sent to the plants of other divisions. Thus they have fine opportunities to become thoroughly acquainted with ventilation, methods of mining, conditions of seam occurrence and the thousand and one details connected with coal mining. An ambitious fellow would have every opportunity to satisfy his desire for information along coal lines.

After following the details of this system of gas analysis and control, it would be amiss not to enlarge on some of the other and more or less related activities of the Consolidation laboratory. The same guiding hand has to do with all such interests; in the laboratory, Mr. Haas is assisted by W. D. Barrington, assistant engineer of tests.

The chemistry and physics of coal are most important adjuncts of the field of mining. An interesting description of the laboratory of the Consolidation Coal Co. appeared on page 235 of the Aug. 11, 1917, issue of *Coal Age*. As the organization of this establishment was perfected its activities broadened. Here all materials and supplies purchased are analyzed and a great deal of other work is done. Coal is tested frequently enough to keep track of all changes and conditions of seam in the mines. In this way the company maintains a high standard of preparation of all coal shipped. Government regulation of coal distribution is supreme; each shipper disposes of his product to points designated, different grades of coal being diverted to the trade best served by coal of certain characteristics. The Consolidation sometimes takes the initiative in such matters, being guided by its complete knowledge of coal leaving its mines—a discretion concurred in by the authorities.

Considerable bacteriological work is done in this laboratory on the water being used for drinking and domestic purposes, as well as a complete chemical analysis of water in connection with boiler feed-water supplies. The drinking water is given especial attention; its use is stopped at once when it is found to be unfit for such purposes. The wells are cleaned out and sterilized with a chloride of lime treatment. Immediately after cleaning, another sample of the water is taken for bacteriological analysis and results determined before the people are permitted to use the water again.

The laboratory at Fairmont is not duplicated in the other regions, but each division of this company has a laboratory equipped to handle minor analyses of gas. Delay in receiving the results of gas analysis for ventilation control would rob the system of most of its benefits. The main laboratory is equipped to carry out complete analytical work on coal and also to make calorimeter tests for heating value. The company able to run a laboratory of this kind is fortunate indeed. In addition to the routine work of an establishment of this kind, there is opportunity for considerable original research. All of this information is valuable to a company beyond the interest on the investment the establishment represents and the money paid out in salaries to employees and for materials used. The moral effect on the progressive foremen and others connected with the company should act as an incentive to further effort along technical lines. If some of the information obtained was presented in a popular way, it might incite an interest among the motor and machine runners and many others to improve themselves in scientific matters.

The greatest deposit of lignite known in the United States lies in Texas. A strip of territory from 50 to 100 miles wide and over 500 miles long runs diagonally across the eastern section of the state. Under this area there has been estimated to lie about 30 billion tons of lignite.

New Apparatus and Equipment

New Electric Safety Lamp Possesses Many Valuable Improvements

The Koehler Manufacturing Co., of Marlboro, Mass., will shortly place upon the market a new type of miner's lamp, named after its inventor the "Wheat" electric lamp. This lamp differs in many details from preceding lamps of this general type. It is designed for use in gaseous mines, powder magazines, gas or oil vapors, and in fact wherever explosive mixtures of gas or dust and air may occur. Furthermore, since the material of which the lamp is made is chemically inert, it is also an excellent illuminant for use around salty or sulphurous waters, in acid vapors or other places where corrosive atmospheres are encountered. Under such conditions these lamps, because of their non-corrodibility, retain their appearance and perform their intended functions indefinitely without the use of paint.

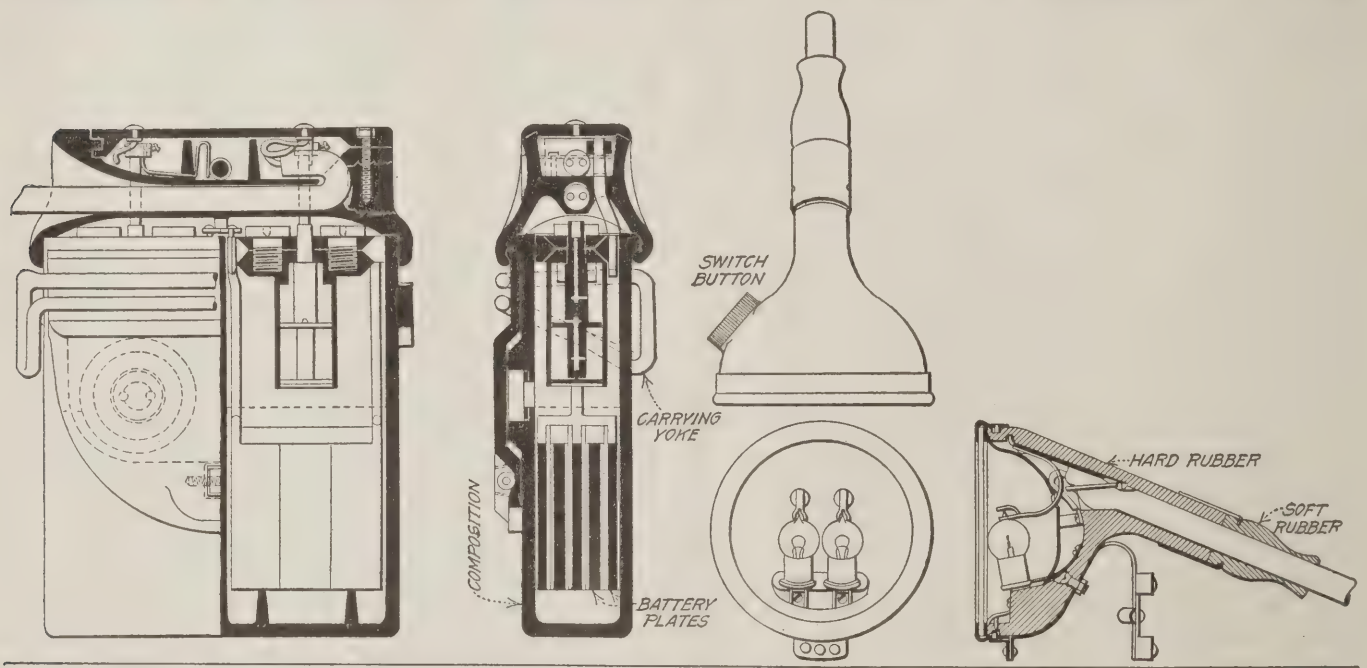

FIG. 1. BATTERY AND HEADPIECE OF THE WHEAT ELECTRIC SAFETY LAMP

The battery, which is of the lead-acid type and of rugged construction, is composed of two cells. These are placed in a hard rubber composition container of heavy construction and held in place by a soft compressible rubber gasket. The electrolyte is of course suitably gas-vented, but as may be seen in Fig. 1 the arrangement is such that no liquid, even under extreme circumstances, can escape. Turning the battery upside down and violently shaking for some time will not permit so much as one drop to leave the container.

Electrical connections to the cap cable are made in the upper portion of the battery case. This portion may be separated from the lower portion, but its removal requires the use of a special key spanner. The storage battery consists of two cells each having two positive and three negative plates. The rated capacity is 6 amp.-hr., but in practice it considerably exceeds this rating.

The conductor connecting the battery and cap lamp proper is of a twisted or spiral cable type properly insulated and covered. In this construction short-bending or kinking of the cable is not injurious. The cable leaves the battery, as may be seen in the cross-section, through a coned opening. It is so securely anchored in the battery that the battery may be safely handled by means of the cable. The cable may be grasped at any point in its length and the battery case shaken violently without injury to anything. The cap lamp might of course be treated in like manner, but being lighter the actual stress upon the cable would be much less.

The cap lamp or hemispherical reflector contains two lamp bulbs instead of one, as is usually the case. A suitable switch permits turning the current upon either bulb (but not both simultaneously) at will. Thus should one filament burn out or one bulb break, current may be immediately switched to the other. The possibility of the miner being left in darkness or of two men being compelled to make a long trip to the lamphouse to renew one bulb is thus obviated.

The two lamp bulbs in the cap piece are each held in place between two springs, one clasping the base while the other bears upon the upper end of the bulb. Should either bulb at any time be fractured regardless of whether the lamp is burning or not, these springs instantly flip the bulb or what remains of it out of place, breaking the electrical contact. This is a safety feature of no small importance.

The cap piece is inspected at the charging station and the lamps tested by turning the switch button that lights them in succession The case is sealed with a small lead seal bearing the lampman's or inspector's mark or initial. This seal may be readily cut should access to the interior of the case be desired, but cannot be replaced by any unauthorized person without detection. The cap piece and reflector are so designed as to spread the light rays over a 7-ft. circle at a distance of 20 in. No spots or shadows are made. The light strength is 22 lumens and the rating of the lamp and battery is 12 hours continuous burning when using a 4-volt, ½-amp. bulb. About once in two weeks it is necessary to add distilled water to the electrolyte until it reaches the level of the filling plug on the back of the battery case.

FIG. 2. BATTERY, CAP, LAMP AND BELT

One feature of this outfit that will appeal to some operators is the ease and safety with which it may be used to fire shots. The charging contacts are on the top of the battery case and almost flush with it. Connection between these terminals and the battery proper is made through an inclosed switch operated by a special key spanner. When it is desired to use the battery for shot-firing the procedure is as follows: The firing fuse wires are brought to and pressed upon the charging terminals. The special key is next inserted in the switch and turned. After a slight rotation of the switch the cap lamp goes out, while a further rotation connects the charging terminals with the battery and fires the shot or shots. A reverse rotation of the switch key first disconnects the charging terminals and then connects the battery to the cap lamp, relighting it. It is practically impossible for any person not holding a switch key as above described to manipulate the switch and fire shots in this way.

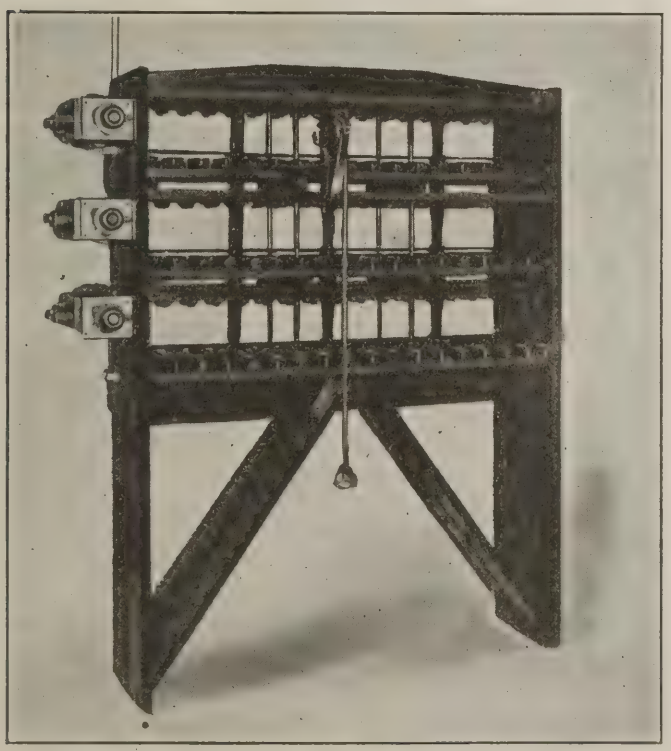

FIG. 3. CHARGING RACK FOR NEW LAMPS

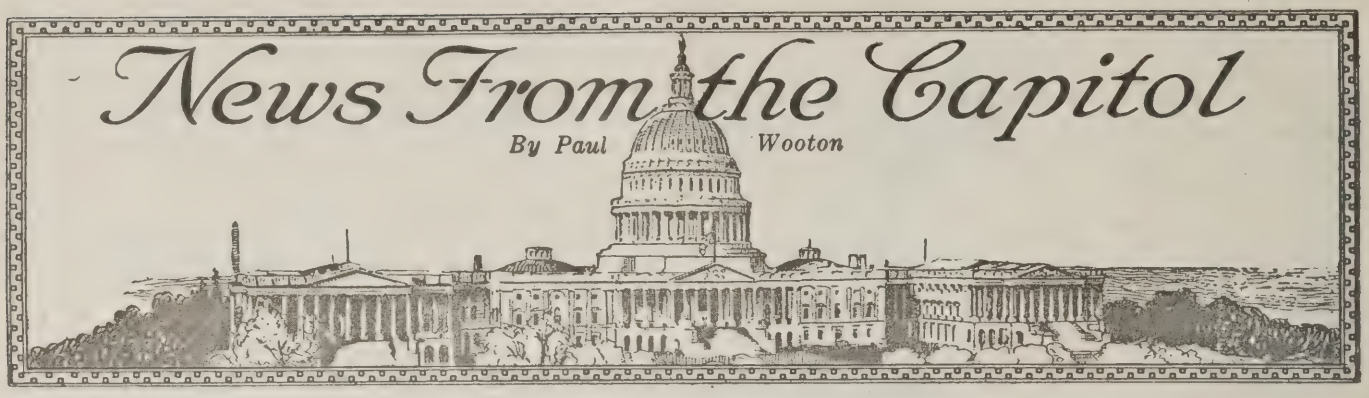
This outfit is worn in the ordinary manner, the battery being carried on the belt and the cap piece fitting the lamp bracket on the ordinary miner's cap. The battery, as may be seen in Fig. 2, is attached to the belt by means of a double welded steel or aluminum rod that embraces the battery case on three sides. The weight of the battery thus comes upon the belt at two points separated by the full width of the case. The cap piece is so made as to clamp securely to the sides or edges of the lamp bracket on the cap. It can be attached readily but cannot be shaken loose.



The total weight of the entire outfit is slightly over 4 lb. The battery alone weighs 3 lb. 8 oz., and the cap piece complete weighs 11 oz. This lamp is now in everyday use at a large anthracite colliery.

Moving Pictures as an Aid to the Salesman of Mine Machinery

The Manierre Engineering and Machinery Co., of Milwaukee, Wis., has introduced the "movies" into the field of salesmanship in order to help sell its coal-loading machinery. The company's salesman carries a moving-picture outfit in his hand, as the ordinary salesman does his "grip," and if he can get 15 min. of a coal operator's time he gives him an interesting movie entertainment on the spot.

The prospective buyer, if he is a large operator, with mines, docks or storage plants, in this manner can see the different varieties of loading in which he is interested at one sitting. He does not have to travel out of his office to see a machine in operation. He is saved time, trouble and much discomfort, and withal he sees more than he could if a machine were actually operating before his eyes, because the views taken of the company's loader working inside a box-car make it unnecessary for one to stick his head inside a box-car filled with fine coal dust in order to view the operations. When taking the pictures the camera was set in an open car, and the coal travels before one's eyes, in clear daylight. The views show the coal coming down the chute from the tipple, into the hopper, thence traveling the length of the belt, or steel apron. The coal is first delivered to the floor, the conveyor rising as the pile grows, backing up, and turning round as the car fills.

A moving-picture man who can show so much in a short time can interest his prospect and gain an audience, where a busy operator would otherwise be inaccessible. The "movie" show may be made to cover the company's complete line of machines—those for loading lime, gravel and other materials—as well as coal. The Manierre moving-picture salesman, it is stated, is at the service of all those interested, and it is believed that the performance is worth the careful consideration of operators who have a coal-loading problem.

Anthracite Distribution Committee Gets Excellent Results

One effect of the Senate coal investigation has been a searching probe of the affairs of the Committee on Anthracite Distribution. It has led the members of that committee to throw open the record of the entire work to all interested. As a consequence, the committee has been given a clean bill of health, not only by officials but by others who have looked into their affairs. Not only has the conduct of the committee been entirely wholesome, but the investigation of its affairs has shown that a remarkable degree of efficiency was maintained. The degree of efficiency is shown by the fact that at Christmas time not a single city in the United States reported a serious need for anthracite with the single exception of Elizabeth, N. J. Emergency supplies were rushed to that point to substitute for a delayed consignment.

Questions asked during the coal hearings inferred that as evidence that improper motives existed on the part of the anthracite committee is the fact that it paid its own office expenses for some clerk hire. The truth of the matter is that the Fuel Administration paid the salaries of some thirty of the employees attached to the anthracite committee. In view of the fact that dozens of men, with far less worldly goods than have the members of the anthracite committee, made important sacrifices to serve the Fuel Administration, the anthracite committee did not feel justified in charging the Government for office rent when they had ample office room of their own which could be used. By using members of their own office forces, a considerable portion of the clerical work at the committee's headquarters was discharged without cost to the Government, but the committee relied upon the paid employees of the Fuel Administration to conduct the work outside of the headquarters of the committee. Even a portion of that work was done by help employed by the Government.

The criticism that anthracite distribution should be conducted from the Fuel Administration's offices in Washington, as was bituminous distribution, is answered easily. The anthracite industry centers in Philadelphia. Practically all of the producers maintain offices there. All the records pertaining to distribution are easily available at that point. The thousands of orders which it was necessary to issue quickly could be given over the local telephone exchange. To have accomplished the same work in Washington, which would have necessitated a duplication of records and distribution machinery, would have cost the Government dearly. In addition, it would have led to endless trouble and confusion from the fact of its geographical position.

The fact that much of the anthracite moved in normal channels has no untoward significance. By keeping it in these channels, confusion is avoided and efficiency secured. There are hundreds of examples to prove that there was no hesitancy in making changes where it was necessary to accomplish the greatest good.

Government's Maximum Coal Prices May Be Relinquished Before End of Coal Year

Probabilities point to the abandonment of the coal-price schedule before the beginning of the next coal year. It is believed that a period should intervene so as to allow any readjustment which may take place to assert itself. Some are of the opinion that the prices may be abandoned Feb. 1, while others think that Mar. 1 will be a better time to remove the maximum prices. The price schedule, of course, means nothing in many districts, even as it is.

It may be decided to allow the zones to stand after the price schedule has been abandoned. While some are of the opinion that prices and zones are interdependent, the majority view is that they are not. The need for transportation continues great, and since the zones have been responsible for increasing the car supply by a considerable per cent., it is argued that the barriers should be kept up for some time to come.

New Zone Changes Enlarge Fields to Which Soft Coal May Be Shipped

Two new zone modification orders, permitting the further shipment of bituminous coal from parts of West Virginia, Maryland and Pennsylvania and into sections of Maryland, the District of Columbia and New England, were made public on Dec. 24 by the United States Fuel Administration.

One order, modifying Bituminous Coal Zone P-1, permits the all-rail shipment of bituminous coal on the Baltimore & Ohio, the Western Maryland and the Coal & Coke railroads in West Virginia, Maryland and Pennsylvania to all points in New England.

The other order, modifying Bituminous Coal Zone P-2, provides for the shipment of bituminous coal from all districts of Pennsylvania to Baltimore and vicinity and to the District of Columbia.

Sweden Offers Permanent Market for American Coal

A cablegram from the American consul general at Stockholm, Sweden, says that, according to a report made by the largest coal importers in Stockholm, there is an unusual market for American coal and that permanency of trade is promised.

Special Fuel Commission Returns from Tour of Investigation Abroad

The Special Commission of the United States Fuel Administration, consisting of Walter E. Hope, S. Brinckerhoff Thorne and James H. Allport, sent abroad to study fuel conditions, returned on the Cunard liner "Mauretania" on Monday of this week. The commission spent two months investigating the fuel situation in France, England and Italy, and before sailing from abroad made a report to President Wilson.

In a cablegram received by Dr. Garfield on Nov. 25 from the members of the Commission, the damage done by the Germans to the coal mines at Lens, France, was said to be so great that production cannot be resumed for periods ranging from eight months to three years.

Mr. Hope joined the Fuel Administration forces in September, 1917, as Director of the Bureau of State Organizations, and was mentioned for appointment as State Fuel Administrator of New York when Albert H. Wiggin resigned early last summer; Mr. Thorne is president of the Temple Coal Co., and of Thorne, Neale & Co.; Mr. Allport is a consulting engineer.

The members of the Commission stated upon their arrival here that before the war England had mined 287,000,000 tons of coal a year, and that last year but 230,000,000 tons of coal had been mined. The situation in France and Italy they said was serious. The members of the Commission also stated that England is releasing 5000 coal miners from the army each day so that they can return to the mines.

May Be a Market in France for Large Tonnage of American Coal

Shortage of coal throughout Europe will make it possible for the United States to have that coal market during 1919, according to information reaching the Department of Commerce. The Department's representative in Paris is authority for the following discussion of the situation in France:

The post-war position of France with respect to coal supplies may make it possible to sell American coal in France during the year 1919. However, until there is some certainty regarding ocean freight rates, it is impossible to say whether American coal can compete with English coal delivered f.o.b. French ports.

Before the war the annual consumption of coal in France was over 60,000,000 tons, of which 40,000,000 tons were produced in the country. It is estimated that the consumption of France proper during 1919 will be in the neighborhood of 55,000,000 tons. Allowance is made in this figure for the reduced consumption of coal by reason of the destruction of thousands of manufacturing plants in the north of France. To this figure should be added, however, 8,000,000 tons, which is the quantity of coal required to feed the iron, steel and textile industries of Alsace-Lorraine, now in French occupation. This makes a total estimated consumption for France of 63,000,000 tons for the year 1919, or about the same as before the war.

It is hoped that French mines during the year 1919 will produce at least 30,000,000 tons of coal. This is slightly in excess of the quantity of coal mined in the year 1917. While there may be a slightly greater production for the year, as mines in the devastated regions gradually resume operations, it must be remembered that the labor needed to mine this coal will in all probability have to be taken from mines in the center of France, with a consequent reduction in the output of that section. There is also included in this estimate of 30,000,000 tons the coal that will be obtained from that portion of the Saar Basin lying in Alsace-Lorraine. The remaining 33,000,000 tons must be imported.

France hopes that England will be in position to export hither during 1919 close to 15,000,000 tons of coal. It is also expected that approximately the same quantity of coal can be imported from Germany during the year. However, if England is not able to export this quantity of coal to France next year, and if conditions in Germany should be such that a corresponding quantity cannot be delivered to France, the French will have to look to the United States for whatever quantity is still lacking. Under the circumstances, it might be worth while for American coal exporters to look into the French situation a little in order to be in position to assist France in case of necessity.

District of Columbia Fuel Administrator Explains Coal-Storing Order

In reply to the request of the Senate for information as to the authority on which he issued his storing-coal order, the Fuel Administrator of the District of Columbia stated:

Upon the issuance of the order referred to the same was given wide publicity through the newspapers of the District of Columbia, and up to the present time there has not been called to the attention of the Fuel Administration any violation of the same by any of the retail dealers in said district. Said order was issued under the authority of the so-called "Food and Fuel Control Act," approved by the President Aug. 10, 1917, which, as I am advised, authorizes the President through the agency of the United States Fuel Administration, to fix the price of coal wherever and whenever sold either by producer or dealer, and to establish rules for the regulation of and to regulate the method of production, sale, shipment, distribution, apportionment, or storage thereof among dealers and consumers.

The order, which apparently does not meet the approval of the Senate, reads as follows:

In order to prohibit the excessive charges heretofore demanded by individuals for the storing of coal in customers' bins, it is hereby ordered by the Director for the District of Columbia, United States Fuel Administration, that on and after this date no person shall charge a sum greater than 75c. per ton for the storing of coal. All retail coal dealers are hereby directed from this day to arrange for and store all coal delivered by them to residences whenever requested by the purchaser, at a cost not to exceed 75c. per ton.

United States Coal and Coke Exports During October

An analysis of the exports of anthracite and bituminous coal and coke during October, 1918, made by the Statistical Division of the Bureau of Foreign and Domestic Commerce, will be found on the last page of the market department in this issue.

All restrictions on the sale and delivery of coke for export were removed by the Fuel Administration as of Dec. 24.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

All is not well with the union in the anthracite region. While the operators are getting reconciled to the chastening of the union the mine workers are rising in rebellion against its discipline and rebukes. Of the 170,000 men in the anthracite region, probably barely one-half are now in the union. And many that are in seem to value membership mostly for the opportunity it gives for factional fights. Membership has all the appeal and furnishes all the opportunity of the celebrated Donnybrook fair; only be it remembered times have changed since that celebrated fair was suppressed in 1855. Eloquence and the rules of debate have almost entirely replaced as modes of action physical strength and the rules of effective shillalahing.

John T. (Jack) Dempsey, of Scranton, is, as said last week, no longer district president of No. 1 District. He was charged with several undue abstentions from his duties. At the time the charge was made, he was suffering from influenza. Nevertheless, Joseph Yanis, of Pittston, the vice president, was placed in the presidential chair. The miners regarded the frequent absences of Jack Dempsey as occurring for a less well justified reason than could be furnished by the grippe.

COMPANY GRIEVANCE COMMITTEES RECOGNIZED

At last the union is recognizing the formation of company grievance committees, those *imperia in imperium* which they have long dreaded in District No. 1. The employees of a large company form themselves into a super local, and they can readily sway the affairs of a whole union district. "Divide and rule" was at one time, and in places still is, the rule of the operator. "I deal with my men unorganized," says the operator. "I deal with the locals unorganized," similarly says the union. "Divide and rule." The Delaware, Lackawanna and Western R.R. Co. Coal Department's employees have already succeeded in establishing such a company organization. Now the Delaware & Hudson Co. mine workers have formed, under the direction of the executive board, a general grievance committee which will represent all the employees of the company. The union attitude has evidently changed, or has had to change, under pressure from within the union. The new grievance-committee chairmen will doubtless often find themselves in conflict with the district presidents. But the board of District No. 1 is committed to the new order, and a campaign will be inaugurated to form such general grievance committees for all company operations.

COMPANY COMMITTEES MAY PERHAPS DO GOOD WORK

No one knows what this will portend. The grievance committee may conceivably be able to do a great deal to pacify unreasonable locals. The heads of the large grievance committees may well be men who will acquire large vision, just as the district presidents soon do. Formed in opposition to the union and to combat its rulings, they might work immense harm to its authority and influence. Formed by the union they may be immensely helpful to that organization.

A meeting, to prepare the way for the new company grievance committee, was held recently, the district executive board and representatives of 18 locals of the Delaware & Hudson Co. being present. There were only three locals that were not represented.

On Dec. 21, 2000 mine workers of the Storrs and Diamond collieries of the Delaware, Lackawanna & Western R.R., Coal Department, went on strike because their payday was not advanced so as to permit them to do their Christmas shopping sufficiently early. The men had served a notice on the company some time ago that they would not work if they were not paid on the Saturday preceding Christmas Day. When a bulletin notice was posted on Friday to the effect that payment would be made on Monday they prepared to go on strike on the day following. On Monday, Dec. 23, the men were paid according to schedule and accordingly they returned to work Dec. 24.

WEST VIRGINIA TROUBLES ARE BEING COMPOSED

Generally speaking, labor troubles are at a minimum just at the present time in West Virginia, although two strikes of a rather serious nature have just been settled or are approaching settlement. It is quite generally thought that there will be no serious disagreements before spring and there will probably be none even then. President Keeney of District 17 has repeatedly stated, both publicly and privately, that the treatment accorded officials and men of the mine workers' organization in the Fairmont region is in every way conducive to friendly relations, every consideration having been shown the miners. In that region at any rate controversies are unlikely to arise in the near future. Many meetings of miners are being held throughout the Fairmont region, but such meetings have to do with details of organization and with other matters concerning the union administration.

There are signs of growing unrest in the Illinois fields, due to the stop which was put to the miners' remarkable prosperity by the signing of the armistice. With mines in the Standard field operating only a day or two a week and those in the Mt. Olive district not doing much better and a general slackening through Central Illinois, and the Carterville district not working more than four days a week, the indications are that the miners will soon be asking another increase in wages. True, they have a joint agreement with the operators, which runs until April, but that has been broken a couple of times and may again prove to be only a scrap of paper. Cutting of prices by the operators is placing a weapon in the hands of the miners, who say that if the operators can afford to make such reductions in price they can also afford to pay more wages.

Coal production in Central Illinois was considerably curtailed recently by a street-car strike which tied up the Illinois Traction System, which traverses the field. The miners who depended upon the traction company for transportation to and from the mines were unable to get to work. But this was not the only trouble, for the traction company does a big coal-hauling business. Many of the mines in the Springfield section, particularly some of the small ones, depend entirely upon the traction company for the hauling of their output. Others are dependent upon the company for transportation of supplies necessary for operation. When the cars stopped running the mines had to close down. The strike has been settled and the line is again in operation.

ILLINOIS MINES ARE RUNNING IRREGULARLY

Independently of the traction strike, there was a marked falling off in employment at the mines in Illinois in November, caused by the influenza in mining towns, the overstocked condition of railroad coal bins, factories, stores, public institutions and residences, by the modifying of Government fuel orders and by the slump in war work.

The mine workers' election is stirring up much trouble in Illinois. John H. Walker, candidate for international president of the United Mine Workers, and Freeman Thompson, president of the Springfield subdistrict, have issued statements charging that there has been tampering with the election machinery, which tampering has gone the length, Thompson says, of stealing and altering ballots.

EDITORIALS

La Ingenieria Internacional

REALIZING the value of internationally exchanging information regarding engineering ideas and accomplishments, the McGraw-Hill Co. on Mar. 1 will begin the publication of a magazine devoted to that purpose. The publishers expect eventually to publish editions in several languages, but the first issue, being planned for circulation in Latin America and Spain, will be published in Spanish and will be known as "La Ingenieria Internacional."

The publication of this new magazine has been under consideration for some years. Its purpose is to afford a medium for the presentation of those developments in American engineering which may be of value to engineers, contractors and manufacturers in other lands. At the same time, following the practice of the present McGraw-Hill publications, a far-flung editorial organization will be developed that will draw into the paper the best of engineering practice in Latin America, in Spain and in other countries where Spanish is spoken. Aside from its performing this function, the new magazine will greatly develop international goodwill and will be a medium whereby American manufacturers engaging in export trade can carry their message to prospective buyers in foreign lands.

It may be a cause of surprise that the McGraw-Hill Co., whose specialized papers circulate so widely overseas, should establish a magazine to serve the foreign field. The reason, however, is not hard to find. The present highly specialized papers appeal only to those who are situated where engineering enterprise has made such progress that there is room for the specialist and need for the last refinement in equipment and design. But everywhere the world over are territories newly developing, where the engineer, the contractor and the manufacturer must each turn his hand to many lines. It is to serve the general practitioner so situated that the new magazine, and its later companions in other languages, will be started. The specialized papers in English will still hold their place as the recorders of the best in the advanced practice of American engineering.

Now the Tune Changes

DURING the war the call came for a large tonnage with only a few men available. Now we are seeking rather low cost and high quality. While the conflict lasted we ushered out, alas too often, the man who promised us less coal breakage and a better prepared coal. He comes back now with a stronger plea, and the promise that quality will assure the operator of steadier work.

But principally does high cost of operation perplex us. No longer are we able to say that every ton of coal, however expensive, will add to our earnings. All that is mined must be cheaply mined, and only by a generous use of machinery can that end be accomplished. We now have time to install these devices. When the stress of conflict and the daily round of work confronted us, we had no time, labor or material to build nor moments or inclination to contrive. It is different now, and like prudent captains of industry we have sensed and evaluated that difference.

The pernicious cost sheet, now again enthroned, demands hourly consideration, and its perusal sharpens our wits and makes keener than during the war our search for ways and means of reducing the unnecessary employment of labor. We cease tabulating our tonnages, and we commence again to chart our costs, for perhaps they will count as much as 90 per cent. of all considerations, toward the close of the coming year. We are already beginning to fear that a large tonnage will soon only serve to make us money by keeping down the cost per ton. Dextrous we have been in increasing output; we shall not fail when our work is the decreasing of costs and the improving of product.

States' Rights and Mining Education

ILLITERACY in the United States reaches a higher percentage figure than in any other of the great nations of the world. We pride ourselves on our school system, and on the whole we have good reason; for, averaging conditions, we have schools that will show most favorable comparison with those of any other nation. Our city schools and most of our rural schools surpass those in other countries. But there are other schools, a few of them in mining communities, that are a discredit to our high standard.

The trouble is that our schools are under local control and supported largely or wholly by local finance. The result is that the school boards are typical of the communities they represent. If those communities have no education, they desire none for their children; and if they have little literacy they are anxious to expend but little on the training and development of their youngsters.

As a result, while a cultured community readily sustains good schools, any community that is but little educated has poor schools and often, when seeking teachers, calls on the graduate scholars of these same schools, without any outside training, to take up that burden. The schools therefore tend to get less efficient rather than more efficient year by year. Nepotism is rife. The schools are filled with "the sisters, the cousins and the aunts"—to say nothing of the daughters—of the school directors.

Some improvements have arisen from state interference. In areas with arrested development, or where the educational status has even moved backward, the school management is being toned up by the action of the state boards of education. Still the progress is

slow and halting. The political control in some states is deplorable. In some others the interest of the whole state population in education is only lukewarm.

As a result we have areas of some states that are unsafe for citizens of long residence and positively dangerous, even deadly, for outside strangers such as coal operators and their agents, however honest and even helpful may be their intent. More education that will open the eyes of the people in these remote districts to the fact that matters are better handled elsewhere is badly needed. So long as the people are ignorant they will make poor mechanics and even poor laborers. They will continue to be suspicious and clannish, and their first thought will be of secret violence and not of mediation and discussion.

Not only that. So long as rural communities are content with inefficient schools for the native-born, there will be no night schools for our foreign workmen. Americanization may go ahead—in the courts—but will stand still in the hearts and the homes of the foreign-born. The foreigner will remain a foreigner, though in his hand he may hold a gaudy piece of paper—a certificate of naturalization—that will in no way direct and guide his life. It will give him the power to wreck our governmental machine; it will not prove that he possesses, nor will it grant him, the ability to run it.

The condition is made the more deplorable because the burden of better education in a mine village falls largely on the operator. If he is progressive and forces the local officials to become active and provide good schooling, he has to pay the greater part of the bill out of his dividends. It is right that he should, but it is not right that while the operator in one place pays this heavy tax the operator in another place is permitted not to do it because the people in that particular community are too ignorant to call for such an expenditure. The result of the discrimination is that the man who has good schools at his mine village is by that fact, at a period of close competition, apt to find it harder to run his mine than his neighbor finds it where adequate schools are not being built and, when built, are not being properly sustained.

No wonder that there is talk of turning the matter over to the Nation, as is the practice abroad. The Federal authorities would then have directive power. The help to the local schools would be evenly distributed, not only between operators in one state but between operators the Union over. All the mechanical aids that contribute to successful teaching could be put into every school. Films and phonographs would teach English, mining, safety, history and hygiene, and wonderful would be the results.

But there is a "nigger in the woodpile" in regard to national assistance to local education. And that "nigger" is the negro. Federal authorities will stress racial coeducation to its last consequences, while certain states will emphasize the sacred right to resist the mixing of white and black. National assistance, if given, will be predicated on a disregard of the color line. As a result the states with colored folk—the most backward of any and the most needful of help—will refuse the Federal aid. There will be no bettering of conditions where betterment is most needed.

The outcome, if Federal assistance is provided, will be that the states where education is needed most will pay for the education of those where it already is most generously supplied, and the states which already have good educational establishments will pay nothing to those that have only indifferent schools.

Federal aid is thus unlikely and perhaps undesirable. The states' desire for "self-determination" will, as often before, work to their individual disadvantage. Yet there does not seem any other solution of the problem than state control and state support of local education. All we can hope is that the states which have done badly in the past can be induced by educational propaganda to take heed to their ways and to do better hereafter, thus spreading enlightenment into the Nation's darkest corners, and lightening the financial burden resting on any individual by the fact that all must bear a like impost no matter where their operations may happen to be located.

Why Not Attack the Big Items?

NIBBLING is characteristic of mice rather than of men. When therefore you look over your cost sheet, as you may have occasion to do many times during the coming year, do not figure on the way in which you can nibble at the small items but how you can bite deep into, and divide in two or three, the costs of the larger items, namely, loading and mining coal.

If you are content merely to nibble at the smaller charges, you may gain therefrom some sustenance but not a full meal. The big items are those which are not under day-labor rates but under a tonnage schedule. For years you have left them alone. You reasoned that they were irrevocable, but since the war you have learned how tonnage per man could be increased if only you were willing to put a little more into the other costs and to put a little faith into your business, relying on greater production to prevent those other costs from increasing per ton when they were increased per plant.

One reason for low production has been a fear on the part of the miner that the rate per ton would be lowered if he put out a large tonnage or yardage. Another has been that the operator did not back his men with adequate power, equipment and supervision. He pared the variable costs to the quick and thus coöperated so poorly with the miner that, despite the fair and even generous tonnage rate, the miner could not hope to make a good living.

Mine coal by the day and back up the miner by the support of everyone—the superintendent, the foreman, the driver, the tracklayer, the bratticeman, the pumper, the blacksmith, the car repairer, the dumper and the trimmer, and see if, while paying a good day wage to the mining force, a large reduction cannot be made in the loading cost. Even more; put in every loading device that will increase individual output. Accept the coal loose in the car and not methodically built up: if coal is not topped so generously less will be spilt on the road.

Of course, this day-wage plan cannot be started when work is good and men are scarce and little disposed to work steadily and industriously. But when the tonnage wage appears likely to be inadequate and steady work impossible under a day wage, your men may favor the change and the scale may be made generous enough to make them render you not merely compliance but generous coöperation.

DISCUSSION BY READERS

Wage Adjustment

Letter No. 2.—Since reading the interesting letter of W. E. Joyce, on the subject of wage adjustment following the cessation of the war in Europe, *Coal Age*, Oct. 17, p. 752, I had hoped to see a further expression of opinion from readers in this regard.

It is my belief that wages will decline when the peace treaties have been signed, although I do not think they will return to what they were in 1914, the year that the war started. Personally, I have little faith in the hope that there will be such an adjustment of wages as referred to in the letter of Mr. Joyce.

The chief reason for the low state of wages before the war is to be found in the fact that European labor coming to this country was cheap. It is true that these immigrants were paid more, here, for their labor than they had received in their own country where the wages were low and the cost of living was correspondingly small.

To illustrate my thought, let me say that, about 1913, I saw an account in a newspaper of a German mechanic, who had been getting $2 a day in Germany. On coming to this country, however, he was paid $4.50 a day for his labor. He stated that, at home in Germany, he could save money, but here it took all he could make to live. He did not explain why that was the case. It may be that he incurred unnecessary expenses, wasted his money, or lived at a higher rate than that to which he had been accustomed at home.

Again, I know of a man who is making $6 a day, here in Canada. He tells me that, for the same work in New York, he would receive $10 a day; but says it takes more to live in America than in Canada.

Reasons for High Cost of Living

It is, of course, hard to give a good reason for the higher cost of living in one place than in another. It seems to me that the increase of large cities, such as are found in the United States, and the relative scarcity of food-stuffs and other necessary supplies, are largely responsible for the high cost of living. When it costs more for men to live it is natural that they should demand higher wages.

In an address, not long since, President Wilson stated before the American Federation of Labor that "nothing should be done to interrupt labor." He emphasized the fact that strikes and lockouts are as great a disadvantage to labor as to operators, and he is correct. However, it is often quite impossible to satisfy labor, whose demands are generally based on the knowledge that industry cannot go on without their aid.

It is hard to tell to what extent wages may decline, or whether they will decline now that the war is ended. Many people think that business will be dull for some time and that labor will be scarce, owing to the work of reconstruction in France and Belgium, but the scarcity of labor in this country and the export of material and supplies for the work of reconstruction should make business good here.

On the other hand, when peace terms have finally been settled, many things will happen to reduce wages here. The return of men from the front and the closing down of munitions factories will throw many out of employment and no one can foretell the ultimate effect.

Rawdon, Canada. C. McMANIMAN.

Ventilating Power Excessive

Letter No. 1—In an able and interesting article, entitled "Elimination of Power Losses," *Coal Age*, Dec. 5, p. 1021, Graham Bright makes the following statement: "The ventilating system does not lend itself to changes which will improve the load factor. The fan must obviously operate at full speed during the day when there is the greatest demand for other power."

To this statement, some exception may be taken. The fact that the fan motors are constantly running makes them nearly the greatest source of power consumption there is about a mining plant. For instance, at one large company in this state where central power is being used, the fan motors consume 16.2 per cent. of the total horsepower supplied from the power house. They require more power for their operation than the mining machines and are only exceeded by the locomotives, which take 20.2 per cent. of the total consumption. Any saving that can be made in the power required for ventilation will greatly improve the load factor.

Installation of Meters Proved a Revelation

When central power stations were first installed in this state some of the coal companies had meters attached to their different classes of machinery, including their fan motors. The first and second months' readings of the fan-motor meter almost threw the management into a panic. They found that, at some of their mines, it far exceeded all of the other power consumed, both inside and outside of the mines.

With current costing in the neighborhood of 1c. per kw.-hr., and with good producing mines, the ventilating power was costing as much as 7c. per ton of coal mined. The management had been giving the closest attention to the transmission system and the upkeep of machinery; but, the high cost of ventilating power seemed to be something that had escaped their notice, and they now realized that something would have to be done inside of the mines, to reduce the power required for ventilation.

Work was immediately started to put the airways of the mines in such shape that the same or a greater amount of air could be circulated through them with less power. By cleaning up the airways in use, driving additional ones and stopping up leaks, they reduced the charge for ventilating power from 7 to 2 and even 1c. per ton, which was a vast inmprovement.

What Mr. Bright has said about costly transmission losses of power within the mine could well be said of the costly transmission of air within the mines. But, in conclusion, it will not be amiss to advise the operator who uses power, especially if the power bill is rendered from the reading of one main meter, to look with suspicion on his fan motor, it may be consuming more than all of the other motors combined, and let him look for the reason thereof.

Sharples, W. Va. P. A. GRADY.

Freezing of Shaft in Winter

Letter No. 5—Referring to the inquiry of "General Superintendent," *Coal Age*, Nov. 28, p. 1004, it appears to me that he is much like the rat caught in a trap by reason of its taking the bait. When proper provision is made for draining a wet shaft, there should be no difficulty from the shaft freezing in winter; but when this provision has been neglected, one must suffer the consequences. If we stop to compute the expense of from three to five days when the mine must lie idle because of a frozen shaft, the need of providing against such occurrence is apparent.

However, in this case, the trouble is there and must be met at once. As a makeshift, let me suggest that an opening be made in the shaft, at the point where the water enters, and a sump or box be placed there to catch the water, which should then be piped to the bottom of the shaft and pumped to the surface. Or, if the flow of water is not too great, a small pump can be set in., at that point in the shaft, and the water pumped at once to the surface. In any case, care must be taken to drain the column pipe when the pump is not in operation, to avoid the freezing and bursting of the pipe.

EXHAUST STEAM SHOULD BE USED IF AVAILABLE

Where the mine fan is run by steam, it is always a good plan to turn the exhaust steam into the downcast shaft. This plan will often prevent the freezing of a wet shaft, although it presents the disadvantage of filling the shaft with dense clouds of steam. If it is required to make an examination of pipes, steps or ladderways in the shaft, it is necessary, of course, to shut off the steam when so doing.

While these suggestions will probably make it possible to pull through the winter, as soon as suitable weather comes, work should be started on water-rings, constructing them at those points where water enters the shaft, as has already been suggested in the reply to this inquiry. If one can afford the expense, it is a good plan to cement a wet shaft so as to keep out the water. The suggestion of installing steam coils for heating the intake air, and the use of salt or brine to prevent the formation of ice in a shaft are, in my opinion, only makeshifts; and, like the wolf in sheep's clothing, cannot be relied upon when there is the greatest need.

Perryopolis, Penn. R. W. LIGHTBURN.

Letter No. 6.—I read with interest the letter of "General Superintendent," *Coal Age*, Nov. 28, p. 1004, regarding methods of preventing the formation of ice in mine shafts in winter. My experience leads me to think that the comments and calculations made in the reply to this inquiry may, perhaps, prove misleading.

Permit me, then, to give a brief description of the manner in which we have accomplished a double object, by preheating the air entering the downcast. Not only did this prevent the formation of ice in the shaft in winter, which had previously been a source of much trouble, but the method we applied increased the humidity of the mine air to almost 100 per cent.

About four years ago, owing to the mine being considered somewhat fiery, and the return from one split reaching a portion of our old works that was inaccessible and could not be examined, the State Mining Department requested that the circulation in the mine be reversed. The change was made late in the summer and at once set me to thinking what means could be adopted to prevent the freezing of the hoisting shaft, which was now made the downcast for the mine.

Being troubled with ice in this shaft in the winter would mean the loss of many days and parts of days as there was already but slight clearance for the cages. Almost the universal reply to my many inquiries was to the effect that nothing could be done and I must expect to lose one or more hours, of a morning, chopping out the ice in bad weather, and, now and then, it would probably mean the loss of a day, to say nothing of the delay and expense due to broken guides and cages.

My decision was soon made to try out the plan of preheating the air, in a way that I had turned over in my mind many times. In spite of adverse criticism, we proceeded with the plan and met with gratifying success. The first step was to build a small tile house, a photo of which is shown in Fig. 1. The general plan of the house and arrangements of the radiators or heating coils, in respect to the downcast compartment of the hoisting shaft, is shown in Fig. 2.

FIG. 1. TILE HOUSE FOR PREHEATING INTAKE AIR

In the same figure is also shown a small detail of the four sets of radiators, each of which consists of four rows of 1-in. pipes, which were staggered as shown in the figure. These pipes were 10 ft. in length and screwed into a base 7 ft. long. The four radiators were set in pairs, one radiator behind the other so that the entering air was forced to pass between eight staggered rows of pipes before it reached the downcast air compartment. The water condensed in the radiators was drained to a trap, which was so arranged that the hot water could be discharged in a spray down the shaft or run off outside to the feed-water heater.

To complete the arrangement, hinged doors were placed over the hoist compartments of the shaft, so

that when these doors were closed all of the air entering the shaft had to pass through the radiators. In cold weather, the doors were closed at 3:45 p. m. and not opened again until 7 a. m. In very severe weather, the doors were also closed during the noon hour. This heating plan is arranged to use either exhaust or live steam, at about 5 lb. pressure. Ordinarily, exhaust steam is available from 3:45 to 11 p. m., but, from 11 p. m. to 7 a. m., live steam is used.

Humidifying the Heated Air Current

By introducing steam or hot water sprayed into the shaft, the heated air current is enabled to take up and carry into the mine from 12 to 15 times more water vapor than would be possible if the air was not heated.

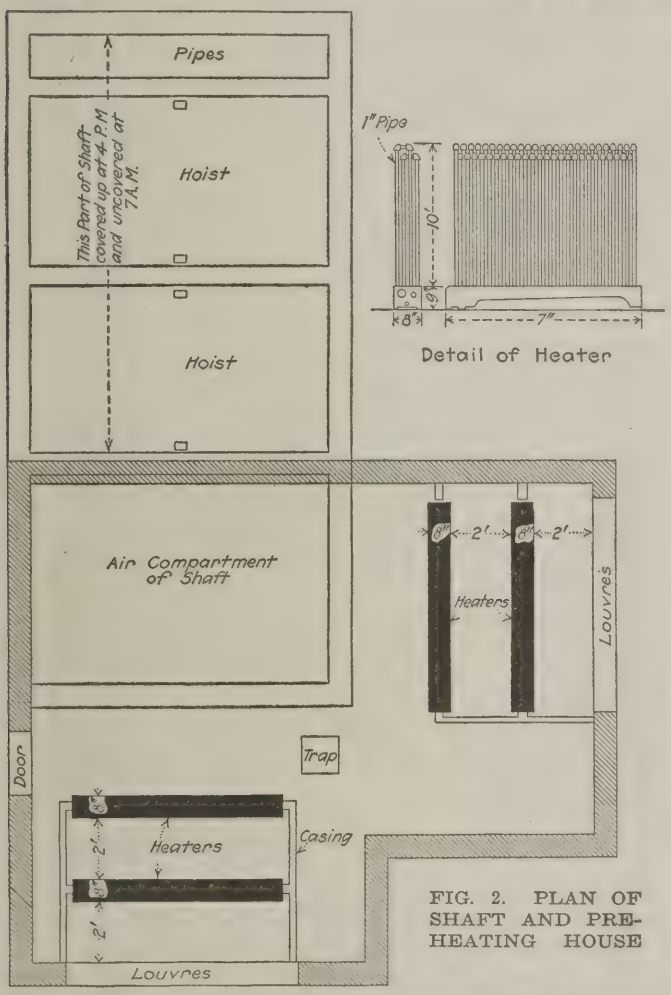


FIG. 2. PLAN OF SHAFT AND PREHEATING HOUSE

Calculating the weight of water vapor carried in a saturated air current of 100,000 cu.ft. per min., we find that, at a temperature of 20 deg. below zero (Fahr.), this current carries 0.385 gal. per min. into the mine. Again, at a temperature of 40 deg. above zero, the same air current fully saturated will carry 5.019 gal. per min. on its way into the mine. A heater and humidifier placed at the fan shaft of a mine would have exhaust steam 24 hr. a day if the fan was steam driven. Our heater is still in operation today, and will probably remain so for the next 20 years.

Before closing, allow me to suggest that the water running into the shaft is materially above the freezing point and must give up its heat units, until it reaches the freezing point and then its latent heat, before it will be changed into ice, which will materially assist in heating the mine air. Of course, wherever possible, exhaust steam should be used, as it is commonly a waste product and contains, roughly, 80 per cent. of the heat in live steam.

Mining Engineer.

Cleveland, Ohio.

[As to the suggestion of this correspondent regarding the heat given up by the water draining into a shaft, taking the temperature of ground water at, say 48 deg. F. and the latent heat of ice at 32 deg. F. as 144 B.t.u., the total heat in the water, above 32 deg. F., and given up, per pound of ice formed, is 144 + (48 — 32 = 160 B.t.u. Then, assuming 10 cars or, say 450 cu.ft. of ice formed in a shaft in 24 hr., which is a bad condition, the total heat given up by the water draining into the shaft and frozen is (160 × 450) ÷ (24 × 60) = 50 B.t.u. per min. It will be observed that this amount of heat is quite inconsiderable in comparison with the 56,976 B.t.u. required each minute, in the case described in the inquiry to which this correspondent has referred. (Nov. 28, p. 1004).

In discussing the practicability of the preheating of intake air for the prevention of ice trouble in shafts, it must be remembered that the severe conditions represented in the reply to this inquiry (p. 1004) do not continue ordinarily more than a day or so when the weather will usually moderate. The benefit derived from the preheating of intake air will doubtless then remove the accumulation of ice that is formed during the more severe periods. This will explain the practical benefit to be derived from a properly installed system, such as this correspondent has described.

Regarding the statement that exhaust steam contains 80 per cent. of the heat in live steam, it is worthy of note that, exhausting under a back pressure of, say 3 lb. gage, at sea level, a pound of steam contains 1150 B.t.u., while live steam at 100 lb. gage contains 1185 B.t.u. above 32° F. This shows that the exhaust steam contains 1150 × 100 ÷ 1185 = 97 per cent., instead of 80 per cent. of the heat in the live steam, under the conditions named.—Editor.]

Travel of Electric Current

Letter No. 7.—Referring to the question of whether an electric current travels in a conductor through its cross-section or over its surface, permit me to add a word or two from my own practical observation, which seems to support the idea that the current travels throughout every portion of the cross-section and not over the surface of a wire, only.

Like others, I have been told that an electric current is a fluid that travels over the surface of a conductor; but practical observation does not seem to support this theory, and I have come to believe that the entire cross-section of a conductor is as much alive as its surface.

One thing that has led me to this conclusion is the fact that steel rails carrying the return from a direct-current system are rendered brittle, in time, by the electricity passing through them. This brittleness of the metal is equally distributed throughout the cross-section of the rails. They are not brittle on the surface only. I have observed that rails never heat, except at joints that are connected by defective bonds, which would seem to tell the same story.

Again, the insulation of wires conducting electricity would appear to obstruct the flow of any current over the surface of the wire, particularly in the case of the wires of an incandescent lamp where they enter the bulb or globe, and where the insulation is so complete that there is practically no chance for the current to pass over the surface of the wire. To my mind, these practical facts seem to demonstrate that the entire cross-section of a conductor is alive. Indeed, I can see it in no other way.

Thomas, W. Va. W. H. NOONE.

Locating the Coal Beyond a Fault

Letter No. 4.—Having had some considerable experience with faults in coal seams, and finding these in different shapes, some upthrows and some downthrows, it may be that I can offer a little suggestion that will be helpful to the inquirer in *Coal Age*, Oct. 24, p. 797. Where we have met these faults, I have always been successful in tracing and finding the seams, although I have not undertaken to sink boreholes from the surface or in the seam, for that purpose.

Let me say that the advice given in the editorial note following this inquiry is quite correct in stating that this fault is "apparently a downthrown." The two boreholes sunk from the surface, if estimated correctly, should afford the means of ascertaining the amount of the dislocation. However, it should be remembered that if the original seam is rising on a 4 per cent. grade, allowance must be made for this, as the seam would have risen 16 ft. in going the 400 ft. to the first borehole, had the fault not occurred.

EFFECT PRODUCED IN FAULTED STRATA

The thickness of the coal beyond a fault will often be found to be quite variable, for a time. This fact will often prove misleading when one judges the continuation of the seam from its thickness. In the case cited, it is very probable that the 3 ft. 9 in. of coal found in the borehole corresponds to the 4 ft. of coal in the X seam, at the fault.

The method that I have pursued in tracing the coal beyond a fault is to study carefully and observe closely the slip of the strata, at the fault. It will generally be found that there is a small leader of coal, which, if followed, will prove a sure guide to the lost seam. Such has been my experience many times. In following this lead of coal, I have always driven as small a place as could be conveinently worked, and enlarged this after finding the coal. This small opening may have to be abandoned and another driven that will afford a better grade for hauling the coal, but that can only be determined after the seam has been located beyond the fault.

Before closing, let me suggest that if this fault proves, as expected, to be a downthrow, it may be found more economical to work the X seam, beyond the fault, through the original Y seam, as these two beds of coal will more nearly correspond in elevation, at the line of fault and can be connected by a short rock tunnel.

Worley, Ky. JOSEPH CAIN.

Letter No. 5.—As superintendent of a small mine, I have often been desirous of gaining outside suggestions, in regard to the many difficulties one meets in mining coal. I realize that this is the desire of the superintendent who inquires the best means of mining the coal cut out by a fault in his mine.

Allow me to make one simple suggestion, which is as follows: In my opinion, it would be well to start a borehole in the roof of the X seam about 10 or 20 ft. beyond the fault. Incline the borehole upward at an angle corresponding to the fault line. Do the same in the floor of the seam, sinking another hole downward in a sloping direction corresponding to the fault. Whether the seam is an upthrow or a downthrow, these boreholes should be able to find the coal, sooner or later.

Manorville, Penn. W. N. R. C.

Letter No. 6.—I have always been interested in studying the mechanical forces that have operated in producing a fault or dislocation of the strata. By a close study of the force that has caused the disturbance, in any particular case, and by applying a few theoretical principles, I have been able to correctly determine the nature of many different faults in practice.

In the case described in the inquiry in *Coal Age*, Oct. 24, p. 797, I was first tempted to agree with the suggestion that this is a "downthrow." However, taking into consideration the 4 per cent. grade of the seam, and the probable pitch or inclination of the fault or slip, I concluded this might prove to be an upthrow.

Since the first borehole is located in a sag in the surface, there is undoubtedly a downthrow between the face of the heading and that borehole. I fully agree with the idea expressed that the coal sunk in that hole belongs to the X seam, and believe that its thickness has been reduced by the pressure caused by the dislocation and movement of the strata.

There are three different ways in which strata may be faulted: (1) One part or section of strata may slip down on the other part or section. (2) Owing to extreme pressure, one part may be thrust up and over, or down and under, another portion of the strata. Again, (3) the strata may be folded, one section being completely overturned on another.

NEED TO CAREFULLY STUDY THE FORMATIONS

One could form a better judgment if he had a typographical map of the country and a correct profile or cross-section. This mine being a drift opening suggests a hilly country, which would enable a good study to be made of the formations, and that would be a great help in determining the character of the fault.

Where a fault line corresponds to the strike of the seam, besides the vertical there is a horizontal movement plainly evident; but when the fault line crosses the strike, it gives greater force to the horizontal movement. This will depend on the inclination of the strike and the pitch of the fault. These are always to me helpful considerations in determining the character of a fault.

My advice is that the two boreholes should have been carried deeper and the borings made with a diamond drill that would have enabled the study of the cores or sections of the strata taken from the holes. Should the two holes fail to give satisfaction, it would be well to prospect further on the fault line; but before doing so, it would be my plan to make a careful survey of the fault to determine its strike and inclination with re-

spect to the seam. By doing this, much needless expense may be avoided.

I recall an instance where thousands of dollars were expended in an attempt to determine a fault at Aguilar, Colo. The work done resulted only in tapping a number of gas and water feeders, without giving any idea of the nature of the fault.

In the present case, it would appear from the plan given in this inquiry that the strike line on the east of the main heading runs, approximately, with the strike of the seam and appears to have a rather steep pitch. On the west of the main heading the fault appears to traverse the strike of the seam at an acute angle and have a somewhat less pitch.

Judging from these facts, if correct, I would say the prospecting should be done on the main heading or at some point east of the same. The carrying out of these suggestions, however, should be done only after careful consideration by the officials on the ground. To give advice, in this case, is somewhat like a surgeon attempting to perform an operation without a strict diagnosing of the case. On no account, however, should the mine be abandoned unless it is known to be at the extreme edge of the coal measures. HENRY BOCK.

Carlinville, Ill.

Perplexities of Mine Foremen

Letter No. 6—Speaking of the perplexities of mine foremen, I am led to ask, Why! Does he have any? You would think not, from the miner's point of view. Even some mine superintendents seem to think that a mine foreman is the most ease-loving, care-free individual in existence.

I well remember my surprise when on my way to the pump and opening a door leading to a side heading I came suddenly on a gathering of almost every worker in the mine. They were holding a mass meeting and I was an intruder.

In response to my query if there was anything that I could do for them, I was informed that there was not; they just wanted to bring that d—— superintendent to time. A few of the men only were talking, as is usually the case, and I stopped and reasoned with them, and succeeded in inducing them to go to work.

Having but recently come to this mine, I was interested in acquainting myself with the prevailing habits of the men and soon found that their regular meeting place was where I had found them. It did not take me long to seek out the mine committee and inform them that they were violating the rules, which they well knew. They promised not to hold another meeting during working hours or in the mine.

At another time, I had been up the main road assisting in clearing away a wreck and, on coming down through a side entry, met a number of men coming out. I asked them quickly "What is the trouble?" They informed me that "Joe had ordered a pair of rails, yesterday, and they had not been put in yet, at 10 o'clock in the morning." With all my persuasion, I could not induce the men to go back.

The situation was about as follows: The motorman and his helper were obliged to shift their empty trip before they could pull out the loaded cars. This bunch of men had loaded their empties, which had been placed the night before. On the arrival of the first empty trip that morning, the needed rails not being in place, trouble arose and the men agreed to quit work until the rails were laid, which they did.

Delay in Repairing Cars Causes Trouble

Another instance illustrating a foreman's perplexities is the following: The brakes on the cars were getting worn, so that they would not hold a trip on the steepest grade. I had talked to the superintendent several times about getting the lumber needed to repair the cars. He never broke my heart by his answer, but always promised to order it at once.

One morning I was up the third left heading and, meeting one of the drivers who did not belong in that part of the mine, I asked him what he was doing over there. He replied that he was notifying the men of a meeting outside. "Why," I asked, "what is wrong now?" "Well," he said, "Dick has hurt his mule and the men refuse to work till the brakes are repaired."

I hastened outside, where I found most of the men who had already quit and others were coming. Going at once to the telephone, I called up the office and was informed that the superintendent was then on his way to the mine. I reported this to the men, stating that he would be there shortly.

Before the superintendent's arrival, I had quite a talk with the men, telling them of my conversations with our boss and how he had promised me that he would get the lumber needed to repair the cars. I ventured the suggestion that, "Possibly, it is hard for him to get the kind of lumber needed." The men replied, "This is the only d—— way we can get anything done here, so we won't work another stroke until the cars are repaired."

The Inefficiency of the Superintendent

After waiting a half-hour or more, the men became restless and wanted to go home. I urged them to wait a little longer and again called up the office, believing that if I could hold the men until the superintendent came he would be able to satisfy them and they would return to work. Again, I called the office only to be told that the superintendent was not in. The manager was there, however, and wanted to know if he could do anything for me.

I explained to him, as best I could, what the trouble was and gave him a full account of the promises that had been made to the men, adding that they had now quit and would not return to work, until the cars were repaired. The committee had come into the office in the meantime and heard what I said over the phone. They asked me, "Who were you talking to?" adding, "That is right, and every word of it is true."

The superintendent turned up about 3 o'clock that afternoon. When he was told that the men had all gone home, he became very indignant and swore he would get even with them. It is needless to say that the cars were repaired in a few days and the men then went back to work. It is true, I believe, that some mine foremen are easily annoyed, and it does not take much to perplex them. However, there are perplexities, at times, that would try the patience of a Job.

Osceola Mills, Penn. S. D. HAINLEY.

INQUIRIES OF GENERAL INTEREST

Drawing Pillars in Machine Mining

We are operating Sullivan shortwall machines, in a flat seam where the coal is from four and one-half to five feet thick, on the room-and-pillar system. The rooms are driven 27 ft. wide and 250 ft. long. The roof is composed of a strong sandstone and the burden over the present workings is about 200 ft. Since installing the machines, we have not attempted to draw any pillars but wish to do so shortly.

If some of the many practical readers of *Coal Age* would give us the benefit of their experience in drawing pillars with this type of machine, the information would be much appreciated. OPERATOR.

Drumheller, Alta., Canada.

Coal Age is pleased to present these practical inquiries to its readers, as they offer good food for discussion and always bring a ready response. Inquirers, however, so frequently fail to give some of the essential data without which it is impossible to give a wholly intelligent answer to the question asked.

In the proposition submitted above, it is most important to know the width of the room pillars, or the distance between room centers, from which the thickness of the pillars can be calculated. It is possible, of course, to assume a two-thirds extraction of the coal, in the first working, or take the width of pillars as, say 4 or 5 yd.; but this may not even approximate the actual condition existing in these workings.

We shall be glad to hear what our practical readers have to suggest, in respect to the use of the shortwall machines, in drawing back the pillars in this mine. The principal factor to be considered, aside from the width of the pillars is the effect of a hard sandstone roof. One must, also, assume a fair bottom and moderate hardness of the coal.

Gravity-Plane Haulage

We contemplate constructing a gravity plane at our mine, for the purpose of lowering the loaded mine cars from the mouth of the mine to the tipple. The length of the incline will be 5500 ft., from the knuckle to the foot of the plane, which will have a uniform grade of 20 per cent. The average weight of the mine cars is 1500 lb. and the capacity 2600 lb. of coal.

We would like to ask if this is a practical scheme and if it would be possible to handle 25-car trips with safety on such a plane. We shall appreciate seeing the question of gravity-plane haulage discussed by *Coal Age* readers who have such planes in operation.

Hooversville, Penn. SUPERINTENDENT.

The successful and safe operation of a gravity plane depends on many factors that enter the problem and must be carefully ascertained before attempting such an installation. Briefly described, the equipment consists of a substantial frame carrying two grooved head sheaves set tandem to each other and controlled by a strong brake.

The haulage rope must be strong enough to stop and hold the descending loaded trip, at any point on the incline. The brake, also, must be capable of exerting sufficient force to effect the same result. The plane should be a straight line, from top to bottom. The main portion should have a uniform grade; but this must be slightly increased at the top and decreased at the bottom, for short distances, to assist the starting and stopping of the trips.

In the operation of a gravity plane, the force producing motion is the gravity pull of the unbalanced load, which constantly increases as the loaded trip descends the incline and the rope is transferred from the upgrade to the downgrade side of the plane. The forces resisting motion are the gravity pull of the rope on the upgrade and the friction of the entire moving system.

There being an equal number of ascending empty and descending loaded cars, the calculation of a gravity system is based on two ratios of live to dead load. For example, the ratio r is the weight of coal (w_c) in a single car, to the weight of two cars ($2W$), one empty and one loaded; or $r = w_c/2W$, and the ratio r_1, the weight per foot of rope (w_r) multiplied by the length of plane (l), to the weight of two cars ($2W$); or $r_1 = w_r l/2W$.

An important factor in the determination is the resistance to the entire moving system, which is best estimated in pounds per ton, expressed as a decimal. Much will depend on whether the cars are equipped with plain or roller bearings and the friction of drum and rope bearings. This resistance, assuming 20 lb. per ton is $R = 0.01$.

The number (n) of cars that will operate successfully on gravity plane when the percentage (J) of grade is expressed decimally is calculated by the formula,

$$n = \frac{r_1(J + R)}{r(J - R) - R}$$

In the present case, assuming a $1\frac{1}{8}$-in. rope weighing 2 lb. per foot, we have

$$r = \frac{w_c}{2W} = \frac{2600}{2 \times 1500} = 0.867 \qquad r_1 = \frac{w_r l}{2W} = \frac{2 \times 5500}{2 \times 1500} = 3.667$$

Then, substituting the values in the formula for finding the number of cars hauled in a trip, gives

$$n = \frac{3.667(0.20 + 0.01)}{0.867(0.20 - 0.01) - 0.01} = \frac{2.31}{0.484} = 5+ \text{ cars}$$

Under these assumed conditions, it does not appear practicable or possible to handle 25-car trips on this incline, without the use of a "barney" to counterbalance the weight of the descending loaded trip, and whose weight will yet be sufficient to draw up the trip of the same number of empty cars. We shall be glad to receive the views of others and learn of their experience.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—Describe the various methods of propping and timbering slopes, gangways and chambers, in anthracite mines.

Ans.—In anthracite practice, the conditions of roof, floor and coal are quite variable, and these, alone, determine the method of timbering that should be adopted in any case. There is little difference in the timbering of a flat slope and that of a gangway, for the same conditions of roof and floor, except that timbers set in a slope should be inclined slightly up the pitch, similar to the undersetting of posts in inclined seams. On steep pitches where the track has a tendency to slip downhill, occasional long timbers should be used for track ties and hitched into the ribs on either side of the slope, so as to give the necessary support to the track and keep it from slipping.

Except where the seam is overlaid by an exceptionally sound roof, double timbers are set on all slopes and gangways. A double-timber set consists of a good cross-beam or collar supported on two legs, which are notched into the collar, the whole forming what is called a "timber-set." These timber-sets are placed at suitable distances apart, depending on the nature of the roof and floor. Where the roof is very frail, lagging of smaller timbers is used to span the space between the sets, thus giving additional support to the roof. Or, at times, the timber sets are stood close together, which is called "skin-to-skin" timbering.

Where the coal is exceptionally hard and overlaid with a fair roof, the crossbars or collars are sometimes hitched into the coal instead of being supported on legs. At other times, short legs are used and these are set in hitches cut in the coal. On steep inclinations, particularly where there is considerable side pressure, the framing of the timbers on gangways must be such as to conform to the conditions.

The timbering of rooms and chambers, in flat seams, must always be modified to suit the conditions of roof and floor. With a frail roof, or where slips occur in the roof, systematic timbering should be followed, the posts being set at specified distances apart, in rows, and staggered. When the seam is inclined, the posts must be "underset," or inclined slightly up the pitch, the amount depending on the inclination of the seam.

Ques.—In case of an accident in which a miner has received a wound severing an artery, what would you do to prevent hemorrhage before a physician arrives?

Ans.—If the wound is in the arm or leg, a rope or strong bandage should be wound about the member, at a point between the wound and the heart. The bandage is then tightened by inserting a stick beneath it and twisting the stick. A small stone or pad should be placed over the artery so that the tightening of the bandage will press the artery more tightly and stop the flow of blood from the wound. Where the flow is from several small arteries, or the wound is in a place that the flow cannot be stopped in this manner, it may be possible to coagulate the blood and reduce or stop the flow by applying sulphate of iron, either powdered or in a strong solution, by means of a sponge.

If there is bleeding from the lungs and the injured person coughs blood, he should be placed in a reclining position with head and shoulders slightly raised. Keep him cool and quiet and, if possible, give him ice to swallow. Restore his confidence by assuring him that there is no danger. If the bleeding comes from the stomach, the blood will look dark and clotted. The man should be made to swallow ice and given ice water to drink; also, an occasional teaspoonful of vinegar should be administered. Keep the stomach cool by applying a towel holding cracked ice to that part. Make no delay in sending for a physician.

Ques.—What proportion of carbureted hydrogen (CH_4) is mixed with the air when a cap begins to appear on the light of a safety lamp, and at what proportion does it explode?

Ans.—The detection of a flame cap in a safety lamp depends not only on the kind of lamp used and the oil burned, but on the experience and ability of the observer to see the cap. Using a common Davy lamp burning sperm or cottonseed oil, the average fireboss will detect the first appearance of a cap when 2 per cent. of gas is present in the air entering the lamp. This percentage corresponds to a proportion of gas to air of 1:50. Special types of safety lamps are often employed, capable of detecting 1 per cent. of gas or less.

The lower explosive limit of pure methane and air is reached when the proportion of gas to air is 1:13, which corresponds to 7.14 per cent.

Ques.—If 30,000 cu.ft. of air is passing with a water gage of 1.6 in., what quantity will pass when the water gage is 2.5 in.?

Ans.—For the same conditions in the mine, the quantity of air in circulation varies as the square root of the unit pressure or water gage. In other words, the quantity ratio is equal to the square root of the water-gage ratio. Hence, calling the required quantity x,

$$\frac{x}{30{,}000} = \sqrt{\frac{2.5}{1.6}} = \sqrt{1.5625} = 1.25$$

$$x = 30{,}000 \times 1.25 = 37{,}500 \text{ cu.ft. per min.}$$

Ques.—Name three essential elements to the efficient ventilation of a mine.

Ans.—The three elements essential to efficient ventilation are: A mine fan of sufficient capacity to produce the required air volume; a proper distribution of the air current in the mine; and, third, well-built stoppings, doors and overcasts that will prevent the leakage of air through them.

COAL AND COKE NEWS

Harrisburg, Penn.

For the first time the Pennsylvania State Workmen's Compensation Board has made a commutation of an award of compensation to an injured man so that he could be reëducated. An order recently issued by Chairman Mackey provides that $300 shall be paid by the Buck Ridge Coal Mining Co., of Shamokin, to Ben Tomashefski, of Renshaw, Northumberland County, one of its miners who lost his sight when cutting coal, it being supposed that his pick struck an unexploded charge of powder and that the explosion blinded him. Mr. Mackey's order says that the employer and insurance carrier have joined in the petition for commutation of a sufficient amount to provide that the man may go to an institution for the blind for some education in order to acquire a new occupation and that the plan for reëducation has been approved. The $300 will be taken off the weekly payments made during the course of the year to the miner, and the order requires the insurance carrier to see that the claimant is placed in a proper home.

United States fuel authorities and representatives of organizations interested in natural gas have been invited by the Public Service Commission to participate in the conference to be held in Pittsburgh on Jan. 8, on the conservation of the supply of natural gas in Pennsylvania. The commission has invited natural gas companies of the state, especially those parties to pending complaints to the meeting, which will be held in the City-County building at Pittsburgh, a special request having been made that they be represented either by counsel or engineering representatives. The conference is to deal with supply, rates not being scheduled for consideration. S. S. Wyer, chief of the natural gas conservation work of the Federal Fuel Administration, has been asked to speak on the supply in Pennsylvania, and conservation will be discussed by L. L. Graham of the Pennsylvania and United companies. They will be the only set speakers, but there will be a general discussion.

Uniontown, Penn.

Production in the Connellsville coal and coke region showed an increase for the week ended Dec. 14. The outputs of 636,826 tons of coal was an increase of 36,245 tons over that of the previous week and 113,105 tons over that of Nov. 23, when the output in this region reached the rock bottom figure of 523,721 tons. The output for the week ended Dec. 14 showed a gain both in coke manufacture and shipments of raw coal, principally byproduct. The coke output of 281,950 tons was a gain of 10,957 tons over that of the week ended Dec. 7, and coal shipments of 213,901 tons was an increase of 29,811 tons over that of the previous week.

Steady increase in output is held by fuel officials and operators as proof that influenza is now rapidly losing its grip. Although the coming of peace, with its resultant relaxation of individual effort, contributed to the low record of 523,721 tons, influenza is held to be the principal factor for the great drop in production which commenced early in October. During the week under review a total of 5701 cars was lost because of labor shortage, 3146 in the coke trade and 2555 in the coal trade.

Charleston, W. Va.

A number of causes operated to materially reduce production in the Fairmont region during the week ending Dec. 21. In the first place cars were extremely scarce, the average not even being 1000 a day, and on the 19th the supply was down to 798, only a number of which were placed at operations in time for early loading. There has been a steady decrease in the supply of cars for several weeks, and a number of direct and indirect causes have been responsible for such a condition of affairs—motive power and traffic barriers having contributed to present conditions. Trouble was also experienced in getting an adequate supply of electric power, at least at some of the mines. Market conditions, generally speaking, are satisfactory, though there is an absence of any brisk demand for Fairmont coal.

So great was the accumulation of unloaded cars from the New River District that coal sold through five different agencies was embargoed, the embargo becoming effective on Dec. 19. This had made it necessary for several large operations to shut down, or at least to curtail operations, limiting their product to what can be handled inland. Orders for New River coal are plentiful. Lack of shipping facilities is the only adverse factor with which the district has to contend.

With a gradual expansion of the markets into which Kanawha coal may be shipped, more of the output of the district is now being absorbed than was the case a short time ago, and consequently a heavier demand is observed, Kanawha coal at the same time regaining a part of its former markets in the West. Producers are sanguine that as soon as large consumers have had an opportunity to adjust themselves to new conditions there will be a much better market for coal. Kanawha district mines were not materially affected by embargoes on tidewater shipments over the Chesapeake & Ohio, since the bulk of the coal from the district flows westward.

Birmingham, Ala.

Steady improvement is being shown in the coal production for the Birmingham coal-mining district, according to Government statistics. There has been no cessation of demands for coal so far, and all Alabama operators seem as anxious as ever to get the largest possible production from their mines.

Meetings were held Sunday, Dec. 22, in all camps of the district, at which organizers of the United Mine Workers urged the men to give their best efforts toward obtaining increased production. Leaders of the organized mine employees have finally decided that the contract between the employees and operators will continue in force until the peace negotiations have been concluded. This will mean that there will be no disturbance of the relationship that exists between the two interests, for several weeks at least. In possible readjustments there is not the slightest doubt in any circles in the Birmingham district that any trouble will be experienced.

Coal producers on the Warrior River are elated over the Government appropriation for development of that stream in the near future. Old equipment purchased from private corporations has been put on a regular schedule, and is being taken advantage of to the fullest extent. The new equipment for the service, on which bids have been asked, will not be in full service until the middle of 1919. The freight rate between Cordova and Mobile on coal is 20c. per ton less by barge than by rail.

New York, N. Y.

The demands of the marine workers in the port of New York wil now be considered by the National War Labor Board, of which former President Taft and Basil M. Manly are the joint chairman. This was decided upon on Saturday last, when the matter was referred to that body by the New York Harbor Wage Adjustment Board. This action was taken by the latter body because the boat owners had notified the Wage Adjustment Board that they could not be bound by any decision that might be made on the matter of the eight-hour day dispute. The Railroad Administration had withdrawn from representation on the Wage Adjustment Board and so far has refused to appoint a successor to its representative. Owing to this vacancy the boat owners refuse to abide by any decision made on the matter of the eight-hour day.

In addition to the demand for an eight-hour day, the workers want an advance in wages.

Having finished the work designated to him, John P. Collins, who was the personal representative in New York City of J. J. Storrow, the Fuel Administrator for New England, will soon close his office at 1 Broadway and return to Boston. Mr. Collins has been here since May last, and has looked after the shipments of the so-called "Storrow" coal from this port; in addition, he has seen that retail dealers located on the New England waterfront have received a good supply of the domestic sizes.

One of Mr. Collins' first duties here was to organize the Long Island Sound Barge Operators' Association, which is composed of 17 transportation companies engaged in carrying coal from the 13 local loading piers up the Sound. Mr. Collins found that these concerns were keen competitors and that considerable delay was caused by the slowness by which tows were taken to New England or empty barges returned. With the new organization completed, these concerns, all of which maintained their individuality so far as business was concerned, handled each other's tows when their own was small in either direction, thereby saving considerable time. The combined fleets of the 17 concerns composing the membership of the association consisted of 43 tugs and 385 coal-carrying barges.

Under Mr. Collins' direction New England has received more industrial coal than was ever before shipped to that section. One of Mr. Collins' hardest tasks was to arrange for shipments of anthracite coal to waterfront towns along the coast of Maine. He was so successful in this that he made an average shipment of five barges monthly, as a result of which these towns have received their allotment of domestic sizes.

Victoria, B. C.

The coal output for November, 1918, shows a material decrease in British Columbia in comparison with the previous month, the difference being approximately 49,476 tons. This is explained by the fact that the Vancouver Island collieries, in almost every instance, failed to do as well owing to the time lost by their employees, many of whom were off for periods of varying length owing to the epidemic of influenza. The production is placed at about 168,006 tons, while that for October was 217,482. The total output for the year 1918 up to the end of November, therefore, is about 2,372,161 tons, or an increase over 1917 of 222,186 tons.

A short time ago the SS. "War Charger," after taking on coal in British Columbia for a voyage to the Orient, had to put back to port for the reason, according to statements given publicity, that she was unable to proceed on this fuel. On returning she loaded with Welsh coal. This reflection on the steaming quality of British Columbia coal is resented, it being maintained that it has been subjected to every test, practical and otherwise, with the best results and that it is so satisfactory that one of the Vancouver Island collieries was able to enter into a contract to supply the Pacific Fleet of the United States naval forces. If the "War Charger" was in trouble of the kind, which there is no disposition to deny, it is asserted that she must have been given an exceedingly poor quality of fuel and that the responsibility should be placed where it belongs and should be generally understood in the interests of the industry. The Board of Trade of Vancouver City has taken the matter up, its members pointing out that the absence of a full explanation of the "Charger's" return is likely to leave the impression in England and elsewhere that a boat cannot be coaled in British Columbia to the satisfaction of the naval authorities. Some declare that the matter is of sufficient importance to warrant the fullest possible investigation by a civic commission.

PENNSYLVANIA

Anthracite

Hazleton—Influenza has again broken out in this region. At Eckley the Lehigh Valley Coal Co. has been hampered by the sickness among its employees. At Weston and Oneida the same company has a number of men off daily, due to the "flu." The labor disaffection in the First District (Wilkes-Barre) has not reached this field, and the men apparently are pleased with the recent wage increase.

Jeddo—The G. B. Markle Co. has employed thirty Mexicans who were recently released by the Bethlehem Steel Co. The Mexicans will work in the company's mines as miners' laborers.

Upper Lehigh—Thirty men were recently laid off at the Upper Lehigh colliery. The new breaker, which is electrically operated, is much smaller than the old one and it can be run with fewer men.

Hazleton—The Worthington Pump and Machinery Co., maker of munitions, has laid off nearly all its men, and many of them have been idle for the past four weeks. These are men who formerly held mechanical positions at the mines, and their places are filled. Operators still report a serious shortage of miners and miners' laborers, but the former munitions workers seem to prefer idleness to taking that class of work.

Hazleton—Anthracite coal operators in the Lehigh region are opposed to the movement started by the National Polish League to enroll Polish miners and other industrial workers for the purpose of inducing them to return to their native land, on the ground that the plan would seriously interfere with maintaining a maximum tonnage.

Nesquehoning—December marked the sixtieth anniversary of the fire at Summit Hill, and also marked renewed efforts on the part of the Lehigh Coal and Navigation Co. to "kill two birds with one stone," by starting a new stripping to get more tonnage and to attempt stamping out of the fire at the same time. Over $1,000,000 has been spent to confine this mine fire. It is now hoped to save tens of thousands of tons of coal out of the fire before it shall be consumed. A large force of men have began work in a new sector with steam shovels. The plan is to strip or remove the top of the mountain that overlies the burning section and take away veins of coal that lie in the path of the fire. The area to be stripped is 400 yd. wide and a mile long. The average stripping depth is 40 feet.

Scranton—So as to insure responsibility for mine caves, the Hand estate and other Scranton interests controlling the Park Hill coal tract, have refused permission to five or six companies, including the Delaware, Lackawanna & Western R.R., Coal Department, which have negotiated for the lease, to mine the 5-ft. and 4-ft., the two top veins of coal, unless the operating company will assume all responsibility for damages occurring to the surface and buildings. It is said that this condition has proved the stumbling block so far in the different negotiations, but that three-fourths of the ownership, consisting of out-of-Scranton residents, are standing pat on the proposition.

Edwardsville—Barring unforeseen accidents, the new $2,000,000 steel breaker of the Delaware, Lackawanna & Western R.R. Coal Department, which was referred to in the news pages of *Coal Age*, Dec. 26, will be in operation by spring. The new breaker is designed to have a capacity of 8000 tons daily, which is double the capacity of the old wooden breaker it will displace. The coal will be prepared in nine sizes.

Bituminous

Pittsburgh—The tipple of the Pike County Coal Co., which was completely destroyed by fire a short time ago, has been rebuilt and is now in full operation. The contract for the reconstruction work was placed with Roberts & Schaefer Company.

Smithfield—The Russell Coal and Coke Co. has purchased five acres of land of the Henry Mathiot tract, near here.

Indiana—A company has been organized and has taken several leases on a large acreage of coal land between Savan and Locust, Indiana County. Several openings which have been operating as wagon mines will be improved and the coal will be brought to a central tipple to be erected on the Work farm. The shipments will be made over the Buffalo, Rochester & Pittsburgh Railway.

Black Lick—The Hetrick Coal Co. is constructing a tram road 2000 ft. long from its mine to the tipple of the Smith Coal Co. The mine was formerly operated as a wagon mine and has considerable development under way. It will add about 100 tons per day to the tipple tonnage of the Smith operation.

Homer City—Henry Reed has sold his mine, which is opened on the Sutter farm near Meco, to George Bulga, of this place.

Locust—The Locust Colliery Co. has completed several new miner's dwellings here. They are of the modern type and of excellent structure. Since the installation of electrical machinery in the mine a few weeks ago the production has been doubled.

WEST VIRGINIA

Williamson—Information from various parts of Mingo County, where there were many wagon mines opened during the war, is to the effect that every wagon mine in the county has been closed down. West of Williamson many of the larger mines have also suspended operations because of zone restrictions, and other mines are being operated on part time only.

Beckley—Early in January the improvements now under way at the plant of the Clyde-Pocahontas Coal Co., at Besoco, Raleigh County, will have been completed. The company is now installing a new generator and is completing the erection of a new substation.

Macdonald.— Supplementing previous mention of the extensive improvements being made by the New River Co. in its power facilities in connection with the operation of its mines at Sprague, such improvements are to cost in the neighborhood of $40,000. The new substation carries two 150-kw. sets and the building which houses the equipment is of brick, with concrete base and floors and a steel roof. It is about 35 x 45 ft. in size. The station has been in operation for about three weeks. A similar power plant is being built by the company at its Skelton operation, 14 of these substations already having been installed for the company.

Bluefield—In an explosion early on the morning of Saturday, Dec. 21, in the Havaco mine of the New River Pocahontas Consolidated Coal Co. at Havaco, near Welch, two men were killed and two members of a rescue party were overcome by afterdamp, when their gas masks leaked. The dead are: John Farmer, mine foreman; Samuel Jones, pumper; Fred Paulick, miner; Martin Harrock, miner. The Havaco is a shaft mine. Rescue parties were at work early, but were unable to penetrate to the point in the mine where the explosion occurred. So far the cause of the explosion has not been determined.

INDIANA

Vincennes—The first mine rescue station in Indiana will soon be in operation in Vincennes. William H. Forbes, who will be in charge, announces that he will have everything in readiness for an emergency within the next week. Until the completion of the new addition to the Vincennes Federal building the station will be maintained in the city hall. The equipment on hand includes ten Fluess type of self-contained breathing apparatus, each weighing 35 lb. Mr. Forbes expects the United States Bureau of Mines to provide at least ten apparatus of the Gibbs type, which are somewhat different from the Fluess, although both are made so that the man wearing them does not have to depend upon air from the exterior. Microphones and geophones, which are now in the possession of the United States Bureau of Mines will probably be shipped to Vincennes and used with the other devices for rescue work. These instruments can be used for the purpose of determining the location of men entombed in coal mines. In addition to the mine rescue work public classes in first-aid to the injured will be conducted in Vincennes and probably in Bicknell.

ILLINOIS

Carlinville—That Macoupin County, Illinois, is to be a greater coal-mining district than any oldtimer ever dreamed of is further demonstrated with the development of the field near Plainview. A. W. Crawford and his son, A. M. Crawford, have promoted many of the fields of the county and they are now interested in the Plainview developments. Drills have been ordered and prospecting will be begun at once. If coal is found in paying quantities the right will be paid for according to the terms of the options now held on many hundreds of acres of land in that vicinity.

Carlinville—A strike of ten days on the Illinois Traction System seriously interfered with the output of coal in this district. Many of the mines, especially smaller ones, depended entirely upon the interurban line for the transportation of supplies necessary for the operation of the mines. When the cars stopped running the mines were forced to close.

McLeansboro—Several test holes have been bored in Hamilton County which show a vein of 7 ft. 9 in. at a depth of somewhere near 700 feet. Options have been taken on land and work of organizing another coal company has been begun. The land in question is north of McLeansboro.

Carlinville—On Dec. 14 the Carlinville Mining Co. struck the coal seam in its new shaft. The seam is 7 ft. thick with a good roof, and the quality of the coal is said to be good. The mine was started about three months ago and the work has been pushed rapidly. The work of opening up the entry and placing the mine in full operation will proceed as rapidly as possible.

IOWA

Des Moines—The Blount Coal Co. is abandoning its American mine, west of the city, and at present is drawing pillars. The equipment will be moved to the company's new Interurban mine, which is to have a capacity of 400 tons per day.

Foreign News

London, England—London can get coal from Spitzbergen cheaper than it can be delivered from the collieries of Newcastle, and of a better quality. Enough coal is available there to pay the cost of the present war.

Victoria, B. C.—Diamond drilling of some coal property situated near the Sable River, Vancouver Island, is to be undertaken at an early date. A road now is being constructed up the river to permit the shipment of machinery to the prospect.

Nanaimo, B. C.—The Granby Consolidated Mining, Smelting and Power Co., Ltd., has awarded the Roberts & Schaefer Co. a contract for the erection of the coal washery to be located at the new mine near Cassidy's Siding. This company has completely equipped the tipple at this point, installation comprising Marcus picking table screens and loading booms.

Prince Rupert, B. C.—The coal problem has become so live an issue in this city that the City Council has appointed a special committee to investigate and report. It was charged recently that not only were the consumers of this community required to pay exorbitantly for their fuel, but that what they bought was much below the standard of first-class domestic coal. It seems that the Telkwa mine, situated on the Grand Trunk Pacific Railway, a short distance from Prince Rupert, has been unable to meet the demand chiefly because of difficulties encountered in obtaining transportation facilities. However, bunkers now have been built at a mine, a siding constructed, and arrangements effected which it is said will permit the shipment of a carload a day to the city.

Berlin—Under date of Dec. 23 the *Tageblatt* says it is informed that new strikes have broken out in the Silesian coal field, as a result of agitation carried on by agents of Dr. Liebknecht, radical socialist leader. [The Silesian coal field is in Poland.] The agents succeeded in inducing the miners to repudiate an agreement that recently had been entered into with the mine owners. The present Silesian output is half that of normal times. The Rhenish Westphalian coal fields also are partly paralyzed by a strike which has cut down the usual output one-third. The Socialist *Vorwaerts* declares that the entire industrial activity of Saxony will be crippled within two weeks unless more coal is assured.

Sydney, N. S.—Another development has come about in connection with the dispute concerning the operation of the submarine coal areas at Sydney mines. Some time ago the Nova Scotia Steel and Coal Co. sought from Fuel Controller Magrath an order granting it the right to operate on some of the Dominion Coal Co.'s areas. After hearing the case the Controller recommended that a 500-ft. strip of coal to the south part of the Princess mine should be taken from the Dominion Co. and given to the Nova Scotia, and that a 1000-ft. strip north of the Florence workings would also be taken. It is believed, however, that the Federal Government has not the power to take either of these areas but, if it desires to act, must expropriate and leave the question of damages and value to the Exchequer Court. It is now understood that the Dominion Coal Co. is prepared to take over the Florence slope from the Nova Scotia and guarantee its continuous working, or in case the Nova Scotia Company will not agree to this, the Dominion is ready to proceed to open its own slope and utilize the coal areas in that vicinity.

Personals

Tipton Stillwell, sales manager for the Boehmer Coal Co., St. Louis, Mo., resigned that position to go with the Bell & Zoller Coal Mining Co., of St. Louis.

George A. Ramsey has succeeded **R. T. Heller** as manager of the Columbus (Ohio) office of the Lake Erie Coal Co., the latter returning to the Cleveland office. Mr. Ramsey was formerly a resident of Columbus.

M. L. O'Neale has resigned as superintendent of the Connellsville Basin Coke Co., near Morgantown, W. Va., to accept the position of mine and mill superintendent of the New York Pyrites Co., at Gouverneur, N. Y.

Captain R. L. Douglass, who has been with the Fuel and Forage Division of the Ordnance Department, has resigned his commission and accepted the position of assistant general sales agent with the Consolidated Coal Co., of St. Louis.

Ben Percy, of Woodward, Jefferson County, Alabama, has resigned his position as general superintendent of coal mines of the Woodward Iron Co., of Woodward, Ala., effective Jan. 1, 1919. His successor has not yet been appointed.

E. G. Ridgway, for the past two years connected with the St. Louis office of the Peabody Coal Co., and previously in charge of the St. Louis office of George G. Pope & Co., has gone into business under the style of E. G. Ridgway, 1220 Syndicate Trust Building, St. Louis, Mo.

F. E. Bourget, who for the past thirteen months has been handling the distribution of bituminous coal throughout Ohio, Michigan, Indiana and West, for the United States Fuel Administration, has resigned to accept the position of special sales agent of the Interstate Coal and Dock Co., with offices at Cincinnati, Ohio.

Horace N. Trumbull, who has recently received his discharge from the Engineers Officers' Training School at Camp A. A. Humphreys, Va., has been appointed advertising manager of the Wellman-Seaver-Morgan Co., of Cleveland, Ohio. Before entering the service, Mr. Trumbull was advertising manager of the SKF Ball Bearing Co., of Hartford, Conn.

Capt. Edward Steidle, of the chemical warfare service, on his return from France will be restored to his old position, that of being in charge of Bureau of Mines Rescue Car No. 1. Captain Steidle went to France with one of the first gas and flame companies and saw much active service. He received a severe wound in the face, which destroyed the sight in one eye.

Joseph E. Thompson, of Benton, Ill., has been appointed director of the department of mines and minerals for the state to succeed Evan John, recently deceased. Mr. Thompson is well-known through the southern Illinois field. He was born in England and his first mining experience was obtained there. Since coming to this country he has had ample experience to qualify him for mine work. He has served in various important positions throughout the mining fields in Illinois.

H. W. Clarke, who until Dec. 15 was connected with the Advertising Service Department of the McGraw-Hill Co., at Chicago, has been appointed manager of advertising for the Chicago Pneumatic Tool Co., Chicago, Ill. Mr. Clarke has been identified with the engineering advertising field for several years. Prior to his connection with the McGraw-Hill publications he spent eight years with the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn., part of the time as a member of the sales and publicity departments and later as Western publicity representative with headquarters at Chicago.

Obituary

Henry D. Thomson, aged 63 years, superintendent of the Fairhaven mine of the Pittsburgh Coal Co., died Dec. 24 at his home, at Carrick, Penn., of heart trouble. Mr. Braddock was born near Braddock and had lived on the South Side and in the Pittsburgh district. He had been with the Pittsburgh Coal Co. since its organization. For eight years he was superintendent of mines at Willock. A year ago he removed to Fairhaven.

Industrial News

Canton, Ohio—The capital of the Huff Run Coal Co. has been increased from $50,000 to $100,000.

Bellevue, Ky.—The Gorman Coal and Supply Co., capital $25,000, has been incorporated by E. A. Gorman, W. P. Neekamp and A. Z. Litz.

Russellton, Penn.—The Republic Collieries Co. has contracted with the Roberts & Schaefer Co. for a Marcus screen to be installed in its tipple at this place.

Cleveland, Ohio—The Cambrai Coal Co. has been chartered with a capital of $300,000 by E. S. Wertz, E. K. Geiselman, Joseph G. Breitenstein, D. E. Wertz and E. J. Wertz.

East Greenville, Ohio—The Dalton Coal Mining Co. has been chartered with a capital of $85,000 by George A. Enos, Fred S. McConnell, E. J. Underhill, R. M. Koob and Harry Abels.

Birmingham, Ala.—The Natural Bridge Coal Co. has been incorporated here, with a capital stock of $10,000. W. M. Holt is president and Palmer Daugette, secretary, Birmingham, Ala.

Cincinnati, Ohio—The Meadows Cannel Coal Co. has been chartered with a capital of $30,000 by Okey Meadows, Louis H. Stone, W. H. Schilderick, John R. Schindel and H. E. Christman.

Ashland, Ky.—The Lackey Coal Mining Co., recently organized with a capital of $100,000, has leased extensive coal properties along Beaver Creek and is arranging for early development.

Clarksburg, W. Va.—The Edgar Coal Co. has been incorporated by E. H. Bell, J. W. Agner, Harry W. Sheets, and others, all of Clarksburg, with a capital stock of $25,000, to operate a coal mine in Harrison County.

Huntington, W. Va.—Owing to the absence of many members of the West Virginia Coal Mining Institute, the winter meeting has been postponed. The next meeting of the Institute will be held in June, 1919.

Hartland, W. Va.—The Moran Coal Co., recently incorporated with a capital of $100,000, has perfected its organization. The company has acquired the plant of the Hartland Fuel Co., and is planning to increase the present capacity of two cars per day. Sam Moran is president.

Columbus, Ohio—W. K. Field, of Columbus, president of the Pittsburgh Coal Co., is also president of the Pittsburgh Coal Co. of Illinois, a new $2,000,000 corporation, chartered to carry on business in the State of Illinois. H. J. Elliott, of Chicago, will represent the company in that state.

Clarksburg, W. Va.—The Edgar Coal Co. has been organized for the purpose of mining coal in Harrison County, the new company having a capital of $25,000. Clarksburg people incorporated the company. Their names are E. H. Bell, Estelle Talbott, J. W. Agnew, Maud R. Agnew and Harry W. Sheets.

Charleston, W. Va.—The Charleston Domestic Coal Co., of which J. S. McVey, of Columbus, is president, has closed a deal whereby it has sold a working property of 900 acres on the Kanawha & Michigan west of Charleston to the Charleston Co-operative Coal Co. The plant has a capacity of about 600 tons daily.

Logan, W. Va.—The Peach Creek Coal Co., with an authorized capital of $99,000, plans the development of coal lands in Logan County, near Hughey, on an extensive scale. Those chiefly interested in the new company include N. E. and George C. Steele, M. E. Robinson, Mrs. Maude Steele and C. S. Minter, all of Hughey.

St. Louis, Mo.—The St. Louis Coal Co., one of the oldest jobbing and operating concerns in the city, was recently absorbed by the Lumaghi Coal Co. The St. Louis Coal Co. had three mines—the Slogo mine, at Marion, Ill., the Coulterville mine at Coulterville, Ill., and the Henrietta mine, recently dismantled, near Edwardsville, Ill.

Columbus, Ohio—Bids will be opened Jan. 6 by George A. Borden, president of the Columbus Board of Purchase, for 1400 tons of Hocking nut, pea and slack for the garbage and refuse disposal plants; 2000 tons of Hocking nut, pea and slack for the water-works department, and 3500 tons of Hocking nut, pea and slack for the municipal lighting plant.

Cleveland, Ohio—The Wellman-Seaver-Morgan Co., of Cleveland, Ohio, has opened a San Francisco office at 415-417 Rialto Building, in charge of Norman S. Ross. Business originating from California, Nevada west of the 115th meridian, lower California and the counties of Josephine, Jackson and Klamath, in Oregon, will receive the prompt attention of Mr. Ross.

Louisville, Ky.—A recent report from Whitesburg, Ky., was to the effect that the Woodburn Coal Co. has about completed its new mining town near Blackey, on the Rockhouse Creek branch railroad, and the new town of Woodburn. The company expects that the branch line will be ready to receive coal shortly after the first of the year, and will be ready to make shipments.

Birmingham, Ala.—The Frisco system on Dec. 21 announced an increase of five cents a ton on coal shipments from Alabama mines into Birmingham, effective Dec. 26. The rates with the increase added make the charge on these shipments 70c. from group 1, 80c. from group 2 and 85c. from group 3. A year ago the rates from these points were 30c. from group 1 and 40c. from groups 2 and 3, the last advance making the rate more than double from groups 1 and 2 and almost double from group 3.

Harrisburg, Penn.—Fewer accidents were recorded in the mines of Pennsylvania during the first eleven months of 1918 than in the corresponding period of 1917. Records compiled by the State Department of Mines show that in the anthracite region there were 419 fatal accidents inside the mines and 89 outside, in the period referred to, compared with 451 inside and 91 outside for 1917. In the bituminous region in 1918, there were 416 inside accidents and 45 outside, compared with 424 inside and 37 outside of the mines in 1917.

St. Marys Falls Canal, Mich.—During the season 1918 a total of 15,770,560 net tons of bituminous coal passed through the canals at Sault Ste. Marie, Michigan and Ontario, as compared with 15,736,654 net tons for the season of 1917, an increase of 33,906 net tons. The total of anthracite going through in 1918 was 2,211,050 net tons, as against 2,562,199 in 1917, a decrease of 351,149 net tons. The United States Canal was opened Apr. 20 and closed Dec. 14, 1918; season, 239 days. The Canadian Canal opened Apr. 23 and closed Dec. 17, 1918; season 239 days.

Philadelphia, Penn.—The famous Greenwich coal piers of the Pennsylvania Railroad are being demolished. These piers at the foot of Snyder Ave., at the time of their erection more than 25 years ago, were the finest in existence, having 80 loading chutes on the five piers. After the site has been cleared, which it is estimated will take a year, the city will erect municipal piers on the ground. The railroad company adready has in use a new series of piers just to the north of the old ones, the new piers being outfitted with modern car dumpers and capable of handling 25,000 tons of coal a day.

Columbus, Ohio—A complete reorganization of the Sunday Creek Coal Co., the New Jersey corporation, has been effected by the election of John H. Winder, president; P. A. Coen, vice president; J. P. Smith, secretary, and C. C. Cook, treasurer. J. S. Jones, the owner, was elected chairman of the board of trustees. The capitalization remains at $4,000,000, and the company will continue to operate under the New Jersey charter. The receivership, which continued for more than two years, was lifted recently upon orders of the court. Mr. Coen will continue as president of the Buckeye Coal and Railway Co., and the Ohio Land and Railway Co.

Bluefield, W. Va.—Chartered a short time ago with a capital of $300,000, the Big Munsey Coal Land Corporation has been launched as an important factor in the coal industry, officers having been elected a few days ago at a meeting held here, with M. H. Pedigo, of this city, as the company's first president. The vice president is A. F. Leckie and the secretary, A. E. Jennings. On the board of directors are William Leckie, M. H. Pedico, A. E. Jennings, A. F. Leckie, W. S. Morris, T. S. Crockett and J. T. Wooten. The Big Munsey company has acquired about 2000 acres of land on Pigeon Creek, in the Thacker field, much of which is covered with fine timber as well as being underlaid with six different seams of coal with a total aggregate thickness of 35 feet.

Seattle, Wash.—The Alaska Bureau of the Seattle Chamber of Commerce and Commercial Club recently received an urgent appeal for a supply of fuel from the Territorial Council of Defense, Juneau, Alaska. W. A. Clark, chairman of the latter body, stated that there was only enough coal in Juneau at that time to last four days and that none was to be found at Douglas City. As Juneau is in the Government Forest Reserve, no wood was available. Mr. Clark was told that the delay in dispatching fuel to the North was owing to the fact that the vessels of the Seattle-Alaska fleet could obtain none in the Northwest. Since then, however, the freighter "Latouche" loaded 800 tons at the Pacific Coast Coal Mining Co.'s bunkers, Seattle, and will discharge it at Wrangell and Juneau. It is feared that if shipments are not maintained more regularly there will be much suffering in the northern British Columbia and Alaska centers this winter.

MARKET DEPARTMENT

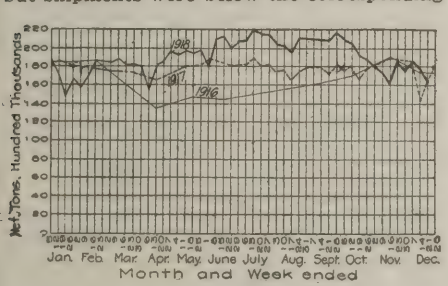
Weekly Review

Decrease in Production of Soft Coal Serves to Tighten Market—Purchasing Agents Now Out of the Market May Find It Hard to Get Coal Later—Anthracite Situation Exceedingly Favorable Due to Mild Weather.

THERE is an element of danger to consumers of bituminous coal in the present stagnant condition of the coal market. Production has declined steadily since the latter part of September, due partly to car shortage, to lack of labor and of late to a lack of demand. Instead of buying coal for their current needs and keeping their stock piles in reserve to meet possible emergencies, industrial consumers are staying out of the market and revert to their storage piles in the belief that prices must soon come down.

If production of coal had been maintained at its former high level, this attitude on the part of buyers would have demoralized the industry; for with an overstocked market prices undoubtedly would have fallen considerably below the Government maxima, and purchasers could have dictated as to quality and price. In fact bituminous operators only a short while ago, were decidedly pessimistic over the outlook. However, from the operator's point of view the situation now evidences signs of improvement. Modifications of zoning restrictions have enabled many mines to extend their shipping radius. Government prices have been adhered to rather generally, due to the fact that production has constantly been decreasing, and consumers who have depleted their accumulated reserves may find themselves unable to get all the coal they want just when they want it.

Labor in the bituminous regions is restless, transportation will slow up during stormy weather, and taking it all in all, the better part of wisdom would be for buyers to take advantage of the present favorable situation and keep the mines working. Government prices will not be abandoned before Feb. 1, and it may be that even if price control is relinquished the zone system of distribution will be adhered to. The need for transportation is as great as ever, and it has been definitely ascertained that the establishment of the zones has been responsible for the saving of thousands of car-miles.



During the week ended Dec. 21 (the latest statistics available) the output of bituminous coal is estimated at 10,136,000 net tons. Production has fallen off in Ohio, Pennsylvania and West Virginia, though a slight improvement is discernible in the reports coming from Illinois and Indiana. For the coal year to date the total output of bituminous is 441,361,000 net tons, more than 38,000,000 net tons greater than the output of the same period in 1917.

Owing to the continuance of favorable weather on the Atlantic seaboard, the demand for anthracite coal has not been urgent. The distribution of the available tonnage has been accomplished with a great deal of efficiency, and at Christmas time not a single city in the United States reported a serious need for hard coal with the exception of Elizabeth, N. J. Emergency shipments were rushed to that point to relieve the situation. Dealers can dispose promptly of their stocks of the larger domestic sizes of anthracite, while buckwheat, rice and barley (the so-called steam sizes) are plentiful and do not move rapidly.

During the week ended Dec. 21 the output of anthracite coal is estimated at 1,839,000 net tons. The total production for the coal year to date is 72,541,000 net tons, a decrease of 1,400,000 net tons compared to the corresponding period of 1917.

WEEKLY COAL PRODUCTION

Bituminous—The decrease in the production of bituminous coal in the week ended Dec. 21, of nearly 500,000 tons, compared with the previous week, was largely in the Ohio, Pennsylvania and West Virginia districts. In Illinois, Indiana and the fields south and west, slight gains are reported, but shipments were below the corresponding

week of 1917. The estimated average daily output decreased from 1,831,000 tons in the week ended Dec. 14, to 1,689,000 tons in the week ended Dec. 21. Production in the week of Dec. 21, 1917, was greater by about 800,000 tons than that recorded in the corresponding week of 1918.

Anthracite—The production of anthracite in the week ended Dec. 21 is estimated at 1,839,000 net tons, a decrease compared with 1,924,000 tons the previous week, but a gain compared with the corresponding week of 1917. The total production from Apr. 1 to date is estimated at 72,541,000 net tons, about 1,400,000 tons less than in the corresponding period of 1917. The record for the calendar years 1918 and 1917, however, will not show as great a difference.

Rail receipts and tidewater dumping for New England were 258,000 net tons in the week of Dec. 21. compared with 326,500 tons the week of Dec. 14, and a weekly average of 542,700 tons for the coal year to date.

Total dumping at the North Atlantic harbors decreased slightly in the week of Dec. 21, from 695,506 net tons to 642,575 tons. New York and Philadelphia reported an increase of 40,000 tons, Baltimore and Hampton Roads recording decreases.

Beehive Coke—The production of beehive coke in the week ended Dec. 21 is estimated at 570,000 net tons, compared with 553,000 tons the previous week, and 657,000 tons in the coresponding week of 1917.

Byproduct Coke—Little change was reported in the production of byproduct coke, the output for the week ended Dec. 21—579,268 net tons—representing only a slight decrease below the previous week. Operators in New York State report continued difficulty in obtaining adequate supplies of coal. Operation below capacity is also reported from Massachusetts and Pennsylvania because of lack of demand for the coke. Lengthened coking time and the use of coal from stock piles that gives an improper mixture, causing the coke to stick in the ovens, are among the reasons ascribed for loss of maximum capacity.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running about the same as for the corresponding week of 1917. Road sales for both immediate and future delivery were less than for the same week of last year. Retailers report that holiday business reached a most gratifying total. Collections are good.

Dry Goods Economist—The higher market for raw cotton has its influence on cotton goods prices. The high of last week (29.44c.) having been superseded by a raw high of 32.60c. for spots, prices for gray cloths at the mills advanced ⅛ to 1c. per yard. Finished cotton goods, however, have not advanced. While the list prices issued by mills and by selling agents are unchanged, however, concessions which could be had in some cases last week are now denied. Jobbers declare that lower prices on cotton fabrics of all classes are out of the question, and expect the quotations now ruling to continue in effect for at least a month to come.

American Wool and Cotton Reporter—There is a large supply of wool in the world, in fact, a great oversupply, as compared with an undersupply of cotton. This is exactly the opposite condition to that which was expected when the war commenced, and it is likely to be a rather long time before anything like a satisfactory condition can develop in regard to raw material. For cotton there has been some improvement during the week under review. This improvement is based largely upon the more or less steady export sale of cotton, and upon improvement in so-called trade buying. Unquestionably, the industry in the United States is consuming less cotton than it has for a long time, and the consumption is still declining rather fast.

Bradstreet's—The larger aspects of things indicate conservatism, much feeling about for definite tendencies preparatory to swinging back to normal, further cancellations, inventorying, increased supplies of labor, downward revisions in prices of metals, divorcing of the government from commercial operations, and preparations for the marketing of supplies that

had been gathered for the purposes of war. The present post-holiday lull in wholesale and manufacturing quarters is more noticeable than a year ago, when war work kept things moving at a feverish pace, and marking time will probably be the rule until salesmen in numbers again take to the road or buyers arrive at the principal markets. Meantime, extensive plans are afoot for seeking trade abroad and here, and while elements of uncertainty hold more or less sway, pessimism is conspicuous by its absence.

The Iron Age—Sellers continue to call attention to high costs and low stocks and it certainly is true that the stocks of pig iron in furnace yards are very low, but there is an increasing tendency on the part of pig iron sellers to accept the new schedule which reduces prices $3 per ton on sales for delivery after Jan. 1. A few furnaces still insist that they will not reduce prices, but it is probable that at an early date the quoting at the lower level will prevail as to a very large percentage of the tonnage still to be sold for the first half of 1919. Statistics show, however, that many furnaces are sold up to July 1 as to 90 per cent. of their estimated production. In finished materials, there is very little buying at the new schedule. This causes no disappointment, for it was not expected, during the holiday season with so much uncertainty existing for various reasons as to the future, that buying would be active.

Atlantic Seaboard

BOSTON

Little inquiry. Railroads cease buying. All-rail movement continues light. No significant developments as to prices. Somewhat more optimism as to the future. Embargo against all-rail route via Shippensburg lifted. Hampton Roads dumpings light for New England. Uncertainty as to marine freights. Rumor that rehandling factors are seeking to "cover" contracts. Some inquiry for high volatiles. Narrow market over New York piers, and surplus of barges. Water-borne coal practically unsalable in open market. Few steamers now in coastwise trade. Anthracite movement improves both all-rail and by water. Railroad Administration standardizes rates on railroad-owned barges. Surplus of broken, egg and pea in most cities; stove and chestnut still scarce. Fuel Administration still holds on to distribution.

Bituminous—Salesmen who are canvassing the trade are able to develop little inquiry. The weight of opinion is all against buying fuel that will not be used for months, and there is too great anxiety on the part of steam-users to get clear of coal now on their dumps to warrant them in making purchases at this juncture. Uncertainty there is as to the future, but there are few who believe that even the fancy grades will command anything over the present Government level when the market opens in the spring. There have been quiet intimations lately that certain standard coals could be had for 15 and 20c. off, but these instances are hard to verify and without doubt reflect more the desire of the selling agent for business rather than any such desire on the part of the operator. Quotations of this kind are of course only for spot shipment.

Even the few railroads that were buying current all-rail to avoid picking up too much from storage have now ceased to place orders, and the market is bare indeed of new business. The railroads are particularly anxious at this time not to commit themselves for any definite price beyond the present, for the whole question of price on railroad supply coal is likely to be raised very shortly, even if the Fuel Administration refrains from withdrawing the fixed price. All concerned will make moves very cautiously the next few weeks.

On the part of several of the Pennsylvania shippers there are extra efforts just now to dispose of smithing coal, especially in box cars, but the outlet in this territory is much restricted, so much box-car coal having been placed through the Fuel Administration during July, August and September. Other than this there seems little consistent effort to place coal. A few of the power plants whose regular source of supply has been affected by influenza or shortage of labor for other reasons have made conservative purchases, but the tonnage has been small and the prices paid were closely in line with regulations.

All-rail movement continues very light, as indeed does all traffic on the New England roads. The average daily receipts for the past week at the five gateways were but 219 cars commercial bituminous, although railroad fuel showed something of an increase. The latter is accounted for by the beginning of deliveries on the part of some operators who failed to make them earlier on their contracts. It should also be remembered that there is still quite a volume of coal due the railroads on long-term contracts made well before coal took its upward swing nearly three years ago. All reports from the different regions show no dearth of car-supply; the low output is due almost entirely to illness and the disinclination of miners to work more than a few hours a day.

The small receipts from every quarter give the trade reason to feel more optimistic as to the future. While the weather is mild and stocks are not being depleted as a year ago, the fact remains they are getting less all the time and shipments are well below actual consumption. It is only a question when buying will begin; whether in April or earlier. A great deal depends upon the tide-water situation and the cost of coal by that route. If the prospect is for high prices in that connection then there will almost certainly be an active market for all the good grade coal that can possibly reach New England by rail. That much seems plain. And it is also a fact that curtailment has not been so drastic in the different lines of manufacture as was feared when the armistice was signed. All in all there is less pessimism in trade circles than two months ago, and there is not the apprehension over the possible withdrawal of the Government price.

A zone modification order made public in Washington on Dec. 24 permits shipments now via Shippensburg from operations on the Baltimore & Ohio and the Western Maryland railroads, thereby reopening the all-rail route to New England points. This is received with a good deal of relief by consumers who made contracts last year assuming the coal would continue to move all-rail and then were obliged later to accept delivery via the New York and Baltimore piers, with all the attendant charges.

At Hampton Roads there is still a large surplus of coal as compared with bottoms to load. Steamers and barges for New England grow smaller and smaller in number, and there are days when the clearances for this territory are practically nothing. Shipments on contract are extremely light, and are confined for the most part to large requirements where storage for more than a few weeks is not readily available. The shippers are looking for a revision in rates from Hampton Roads to Boston, but no intimation has yet been made as to what the new freights will be. Until some announcement of policy in this respect is made by the Shipping Board, it will be impossible to open the way for a new contract season.

Certain of the rehandling factors, however, have already approached their trade with propositions that in consideration of service the past year the customer is looked to for a season order this year, the price to be arranged later, but the contract to be considered "covered." This is what is expected to happen where connections have been strong for a term of years, but it is a little unusual to approach new trade in this way. Other than this there are no developments looking to season contracts.

There are signs of restricted inquiry for some of the fancy high volatile grades. It is natural that there should be dissatisfaction over the treatment accorded some of the consumers of these grades and that there should be attempts to close elsewhere the coming season. This is particularly true in cases where gas coal shippers have insisted that plants take their supply by water in the shippers' own transportation, and now there are some orders in the market for gas coal operators who are in position to send coal all-rail and will commit themselves to that route. Several of the shippers of high volatiles are discouraging in their predictions of light output. Some have gone so far as to say that the moment the Government price is taken off the better grades will soar at least $1 a ton.

The outlet for coals, even of fairly high grade, over the New York piers is narrow and inactive. Bunker demands are greater some weeks than others, but even for such purposes there is hardly a dependable market. Ports on Long Island Sound are taking little spot coal, and one result is a surplus of box barges. Water-borne coal in any port in New England is today practically unsalable, so far as the open spot market is concerned.

Anthracite—The movement of domestic sizes continues to improve all-rail but not to the extent anticipated. For the past week the average receipts were about 340 cars. The mild temperature of Christmas week had its effect upon the big city markets and for a day or two it looked as if coal would be rushed to New England by water in greater volume than at any time in a year. The barges were available and the coal was on hand, but the piers were so congested with the heavy accumulation of cars that undoubtedly a large tonnage was lost to New England. There were crews to load small boxes for New York retailers when the larger craft for this side of Cape Cod were left unattended. In spite of this, however, receipts have increased in several directions and it is now pretty well established that there is a surplus of broken, egg and pea in the hands of many dealers in the larger ports. Stove and chestnut are still scarce, but the companies are contriving to give each customer a share of the desirable sizes.

NEW YORK

Anthracite situation shows improvement. Domestic sizes continue to be short but demand falls off, most household consumers having received two-thirds of their winter supply. Smaller sizes plentiful and restrictions removed from buckwheat. Concessions on barley. Bituminous market unsteady. High grades scarce with fair and poor grades plentiful. Not much change expected during the next few weeks.

Anthracite—The situation shows a general improvement. There is a steadier movement of all domestic sizes, especially egg, stove and chestnut, which have been extremely short in this market for some time; and while the dealers could take care of heavier tonnages, there is plenty coming forward to meet current requirements. With conditions as they now are remaining for a few weeks longer, there are tradesmen who predict an overstocked market. Consumers, most of whom have already received two-thirds of their order placed last spring, are not willing to take the remaining third, and as a result retail dealers ended the year with deliveries slow and in some instances some of their help idle.

New York continues to live up to its reputation as a "weather market." Many consumers lay in only enough coal to tide them over a couple of weeks and then, when a sudden cold wave strikes the city or there is a heavy storm that interferes with traffic, they rush to their dealer with a rush order and expect it to be delivered at once. Present conditions are much the reverse of what they were a year ago, when the thermometer registered from 12 to 18 deg. lower than it registered the first of this week. At that time there was a serious coal shortage, and with the cold wave there was untold suffering, especially among the very poor.

Dumpings at the local docks for the seven-day period ended Dec. 27 amounted to 5691 cars, a decrease of 690 cars from the previous week. For the first 27 days of December there were 23,153 cars dumped, as compared with 19,724 cars for the corresponding period of November.

The situation with regards to the smaller sizes is unsteady. Supplies are steadily increasing and quotations below those made by the larger shippers and producers have been reported. Restrictions issued by the Anthracite Committee on May 27 against the shipment of No. 1 buckwheat and larger sizes to certain consumers have been removed to the extent that buckwheat can now be sold to any consumer who may wish to purchase it. This, it is believed, will go a long way toward keeping the stock of this coal down. The restrictions, however, continue in effect on shipments of pea and larger sizes.

Rice and barley are nearly a drug on the market. Stocks with some shippers are so large that concessions are being quoted, especially on barley.

The prospect of a settlement of the wage scale demands of drivers, engineers and yardmen employed by the retail dealers is not encouraging. Representatives of the State Labor Board, the War Labor Board and the State Fuel Administration have had conferences with the retail dealers and the representatives of the Union, but no satisfactory agreement has been entered into. If the demands of the men are granted it will involve a 50 per cent. wage increase, which would automatically increase the retail price of coal at least 50c. per ton, as the workmen, besides asking for a wage increase, also demand shorter hours of employment. The dealers consider that the advances asked for are unwarranted and beyond reason, some of them preferring to face a strike than to grant the increases. The men are also very determined, and say they will hold out for their demands.

Current quotations, per gross ton, f.o.b. Tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$7.80	$8.55
Egg	7.70	8.45
Stove	7.95	8.70
Chestnut	8.05	8.80
Pea	6.55	7.30
Buck	5.10@6.05	5.90@6.25
Rice	4.65	5.10
Barley	4.15	4.30
Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—There is no activity in the local market. High grades of coal are in good demand, but they are scarce, while there is plenty of the cheaper grades with no call for them. Consumers continue to depend upon their present stocks rather than lay in additional coal of an inferior quality at high prices. Many consumers, too, believe that prices will be lower when the restrictions are removed.

The only salvation of the trade is better coal-consuming weather. But even with lower temperatures no big improvement is looked for until about the middle of the month. Production already curtailed because of influenza and a desire on the part of labor to observe the holiday season, some by devoting several days to hunting, is not likely to show any improvement until about the second week of the month. Even then consumers will not be any too anxious to increase their holdings but will continue to watch the situation closely in the hope of picking up good coals at lower prices.

Producers and shippers are uncertain as to what the outcome will be after Feb. 1, to which time announcement has been made in Washington maximum prices and zone regulations are to remain in force. As has been previously stated, and the same seems to hold good now, the opinion is about evenly divided that prices for the higher grades of coal may advance slightly in accordance with demand and that those for the cheaper grades will decrease in the same proportion.

The matter of contracts is again coming to the front. Conditions similar to those existing last spring are now prevalent. Producers see no advantage in signing up a portion of their output with the price situation as it now is. On the other hand, there are consumers who are willing to make a contract providing a clause is inserted allowing a change in price if there should be one. Producers and shippers contend that there is nothing to be gained by making a contract because of the fact that at least in many instances, if there should be a lower price in vogue, the consumer would find some way to break it unless his shipper would agree to the lower figure. Then it is always customary for producers and shippers to take care of their regular customers, no matter what conditions might be, and at the regular market quotations.

Some shippers have had difficulty in moving refused coal and concessions of 50c. below the Government figure have been heard of. Some of the pools containing coals suitable for bunker purposes are reported as filled. This, it is said, is particularly true of Pool No. 10, and some of the shippers interested are said to be willing to forego part of their extra allowance of $1.35 in order to move their coal.

Reports have been received here of concessions for certain grades of Pittsburgh gas coal. The gas coal supply here is not as large as it was a few weeks ago, and prices are steady.

There were dumped at the local docks during the week ended Dec. 27 5128 cars, as compared with 6413 cars the week previous, a decrease of 1285 cars. For the first 27 days of December the dumpings amounted to 22,091 cars, as against 22,502 cars for the same period of November.

Current quotations, based in Government prices at the mines, net ton f.o.b., tidewater at the lower ports, are as follows:

	Mine, Gross	F.o.b. N. Y., Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite trade still quiet. Weather very mild. Fuel officials urge buying. Credit question to the fore. Pea and egg becoming burdensome to shippers. Stove and nut supply improves. Steam sizes all dull. Buckwheat exemption cancelled. Bituminous short. Holidays cut production. Railroad confiscates best coal. Prices remain firm.

Anthracite—The fact that the local fuel administrator announces through the daily press that the public should not put off buying more coal because the weather is mild shows in a sense there is no active demand at present. Mr. Lewis states that the chances of obtaining a good supply now are probably better than they will be at any time later in the winter, and that consumers are making a mistake in waiting for severe weather before getting coal, when there is likely to be a rush and everybody will want coal at the same time.

After interviewing the largest retail concern in the city, we are more convinced than ever that the orders as originally placed by the householders were greatly inflated. This firm states that refusals to accept coal have recently become so numerous that they doubt if 10 per cent. of the unfilled orders now on hand would be received by the customers were they able to deliver the amount immediately.

Many dealers report their business in comfortable shape. They have no pressing demands that are neglected. A small number of consumers are soliciting credit, and this feature is being given some thought by the retailers. Of course, under the supervision of the Fuel Administration there is practically no competition in the coal trade, and dealers are still in position to demand cash with almost every delivery; the exception being such trade as has never abused its credit. However, the fact that the supply is becoming greater than the demand leads to the feeling that the restrictions of the Fuel Administration will be released almost over night. It is then that the customer will be permitted to go where he will to purchase coal; as a consequence, the dealers will have to once more offer inducements to keep their trade or to gather in new business. The producing companies are watching the situation closely and will make every effort to keep their accounts in good shape.

As to present supply, it would seem that retailers who are affiliated with the individuals are in good shape. It may be their production is above that of the basic year 1916-17, also it is possible that the anthracite committee is not making the same stringent demands as upon the big companies. It is becoming known that the larger operators, those who do not charge the differential of 75c. per ton, are receiving requests from quite a number of dealers to suspend shipments on egg and pea, and wonder is being expressed as to how the business of the smaller houses, especially on these two sizes, is being affected.

Limited production during the holidays and some colder weather will no doubt greatly alter the situation. Stove and chestnut are still in demand by practically all dealers. The largest operating company has made substantial gains where it was delinquent and few complaints are being made.

Another of the large companies has, however, made no progress whatever and is sadly neglecting this market. For some reason the fuel authorities are ordering heavy consignments of this coal in other directions, and it is leaving its customers here in desperate shape. Buyers who had been dealing with this concern exclusively are at their wits' ends and are free in expressing their determination to never again depend entirely on one shipper.

Strange as it may seem, a substantial tonnage of this company's business has been transferred by the fuel authorities to a middle house, and the coal will be shipped from an operation that has no direct selling force. The coal will therefore cost the dealers, and hence their customers, 95c. per ton more than they expected to pay. To say that the trade is objecting is putting it mildly. All the dealers affected will not accept the arrangement, while others say they are compelled to. The concern referred to is fully cognizant of the position in which it is being placed, but apparently will let nothing interfere with its policy of strictly following the rulings of the Anthracite Committee, regardless of any effect it may have on its future business relations with its trade.

The steam coal market is weak. The fact that Port Reading has been embargoed was quickly reflected here in a heaviness of all steam sizes, including buckwheat. Buckwheat has weakened considerably, with rice even worse, barley unsalable and culm absolutely off the market with no likelihood of its return. The buckwheat situation is reflected in a new order sent out by the fuel administration removing all restrictions on this size. It will be recalled that under date of Jan. 17, 1918, buckwheat had been declared a domestic size and no shipper could ship it to an industrial plant without a special exemption from the administration. Under the recent ruling shippers are now permitted to find a market anywhere for this size.

The prices per gross ton c.o.d. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—There continues to be a tendency to a stiffening in the demand for soft coal, but only on account of shortened production. Most of the shortage has been occasioned by the holidays, which the men are inclined to lengthen out even longer than usual. Some operations report strikes due to purely minor differences, such as the cost of furnishing carbide for lamps, which illustrates the tendency of the men to slacken work.

The greatest stringency continues in the best coals, and this week the Pennsylvania Railroad has confiscated a greater quantity than ever of the low volatile coals. In the districts served by the Baltimore & Ohio the car supply has also been somewhat restricted, although in the Pennsylvania districts the average has been somewhat better.

As to price, the general impression now is that the full Government price will prevail until some time in February, for despite any other influences, even mild weather, it is thought the demand up to that time will be sufficient to warrant a continuation of price regulation.

BALTIMORE

Closing days of December see first snow flurries. Soft-coal situation easy, and hard-coal supplies now pour in for trade.

Bituminous—A wee touch of winter has come to Baltimore after a fall and early winter season of exceptional mildness, and the past week saw the first snow flurries. Easy movement of coal-laden cars and a large tonnage production led to heavy deliveries of soft coal to this section. Some few mining districts complained of lack of cars, but the majority of openings were liberally treated. The movement to this section is heavier than the more urgent demand warrants, and some little difficulty was experienced the past week (and is still being experienced) in getting rid of less desirable fuels.

The tendency, in the face of a steady improvement in the grade of coal coming in to this district, is to seek the better classes. There is now no talk of cutting the Government prices, however, and this is accepted as a healthy sign. Many in the trade predict that the specialized coals will sell above the Government maximum as soon as the restrictions of the Fuel Administration are removed.

Anthracite—At last the retail hard-coal trade is seeing a liberal supply released here. The December movement was so satisfactory that the thoughts of famine in the minds of every coal man just before the armistice was signed have vanished. Already some of the more important companies here are asking their customers how much they will take of the one-third undelivered on the books of the coal men. The mild winter may cause some orders to be cut down a bit; and besides, consumers have learned many lessons in economy in burning.

A few of the dealers are still considerably back of their two-thirds delivery, but the inflow of coal is now taking care of all urgent cases. A few dealers are storing a little coal. The month of December will probably have seen a total movement in excess of 75,000 tons of hard coal when the official figures are made up. For the coal year from Apr. 1 to Dec. 1 a total of 435,063 tons was received in Baltimore for domestic and public service corporation use. This leaves nearly 300,000 tons on the city's allotment, to be delivered from Dec. 1. The situation here at present, however, for the first time in months, can be classed as fairly easy.

PITTSBURGH

Holiday curtails production. Contract shipments absorb output. Demand for high-grade gas coal.

Last week coal production in the Pittsburgh district was again quite below normal, on account of the holiday, which was well celebrated. While the market absolutely lacks snap, there being scarcely any buying demand except for special coals, the output is well taken care of by contract shipments and standard grades of coal are held at absolutely full prices. There is considerable demand for high-grade gas coal, particularly from steel works, and it is asserted that if price control were removed gas coal would sell at a substantial premium above steam coal, whatever the steam coal level might be.

Most operators in the Pittsburgh district were in favor of the Fuel Administration retaining control of prices for some time, perhaps to the end of the coal year, and are correspondingly gratified at the recent announcement that the control will continue to Feb. 1, at least.

Industrial consumption of coal has diminished somewhat since the signing of the armistice, but not by a great deal, since the steel industry has been working at practically capacity except for a few closings during Christmas week. It is doubtful whether the steel mills will be working as full 30 days hence, as orders for steel are very light. Domestic consumption has of course been far below normal. Industrial consumers as well as retailers have been drawing upon stock piles and will have little by way of reserves if there is any real winter weather. Requirements of byproduct coke ovens are hardly being met in full. The Pittsburgh district is looking forward to much lighter demands for lake coal next season than was experienced in the past season, when West Virginia's deficit, on account of the special demands of the Navy, had to be made up. The market remains quotable at Government limits, but without any brokerages in addition to regular prices: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

BUFFALO

Big bituminous surplus. Consumers indifferent to the market. Ohio coal trying to get in. No prospect of further shortage. Prices would go down if not enforced. Anthracite in good supply.

Bituminous—The world seems to be full of coal, and it is hard to get consumers interested in it. The outlook is for a surplus exceeding any in recent years. The fact that there has not been coal enough since the middle of 1916 shows what is taking place everywhere. Bituminous output is larger than it was at any time since the war began, and it will be still larger unless many of the mines close down or run on restricted time.

In Canada coal is piled up, and it is almost impossible to sell any. The amount that has paid demurrage is not only great, but it seems to be increasing. Add to this that the railroad yards are blocked with so much coal that a general embargo is feared, and it is easy to see what has become of the market. Some shippers say that they might find buyers if coal was offered at 50c. off Government prices, and in some instances operators are cutting prices a little.

Jobbers are encouraged, though they are aware that their time has not wholly arrived. The change from scarcity to surplus has been made so quickly that it gave them little chance for business. So far all the jobbers get is a shifting of inquiries from consumer to operator. The consumer wants as little of them now as the operator did formerly.

The one point of firmness is that the Government does not propose to throw off the arbitrary price perhaps till February, when the old contract system promises to return. Quotations remain at $4.65 for thin vein Allegheny Valley, all sizes; $4.45 for Pittsburgh and No. 8 lump, $4.20 for same, slack or mine run; $5.65 for smithing and smokeless, $5.60 to $6.10 for cannel, all per ton f.o.b. Buffalo.

Anthracite—The supply continues to increase. A few days more at this rate and the complaint of shortage will cease. It is reported that everybody has at least some coal, and the people who are receiving a full supply are increasing fast. It seems to be the late increase of supply that has helped the situation, but the closing of the lakes was partly responsible. December is breaking the record for mildness. It is a certainty that not half the fuel has been used that was used during the same month last year.

As it appears now, the middle of February will see more coal offered than is asked for, and some say it will come a month sooner than that. After that the big price is all that will trouble anyone. There is sure to be a turn toward some other fuel if there is any to be found that is acceptable. It is said that quite a good many consumers, especially in Canada, have bought bituminous or cut wood for winter. Some country dealers are already flooded with anthracite that they can neither unload in time nor sell promptly, and a few orders are reported by the shippers to have been canceled.

Reports from the upper lakes are not reassuring, but at this rate the roads can help out more or less. The car supply is good as far as reported by the trade, the only difficulty being that the motive power is inadequate and that unused cars hinder the movement of trains. The fear of famine is past.

CLEVELAND

The turn of the year finds steam coal demand still dwindling, domestic consumers with supplies ample for the remainder of the winter on hand, production off fully 50 per cent., operators more and more tempted to shade Government prices. No. 8 coal at 30 to 60c. under the maximum is being liberally offered.

Bituminous—The only ray of hope in the entire bituminous market is the view of some operators that a fair amount of buying will be done in January by steam-coal users whose operations have not been greatly curtailed by the cessation of war work, and who have not been in the market recently because of a desire to work off war-priced stock piles. This buying will not be large, it is believed, but it will prove most sustaining and provide the only big outlet for No. 8 coal until the lake trade again shows some life, which will be about the middle of March.

Probably at no time this winter has the market been weaker and the outlook so cheerless. Although they did a winter business all summer, retail dealers are complaining bitterly of weather conditions. Supplies put in last summer have been so little eaten into because of the mild weather that little or no buying any more this winter is expected. Financially, some of the smaller dealers have been hard hit. Steam-coal users may be said not to be buying a ton just now. Inventory and holiday time partially account for this, but there is no disguising the fact business conditions have been steadily growing worse. The only ones now consistently holding up are the automobile and automobile parts industries.

Holiday time has cut heavily into production, but this is no cause for concern to operators. What is telling, however, is the constantly increasing proportion of maintenance, something which continues whether mines are worked full time or only half. Mine workers were encouraged to take off as much time as they wished Christmas and New Year, a very dissimilar condition from a year ago. Car supply in the No. 8 district has shown quite a drop, having been only 74.42 per cent. in the week of Dec. 14, compared with 82.16 in the week preceding. Lost production due to car shortage in the week of Dec. 17 was 101,700 tons to members of the Pittsburgh Vein Operators' Association of Ohio, compared with 71,350 tons in the week of Dec. 7.

Any amount of No. 6 coal can be picked up in this market at 30 to 60c. off the maximum. Operators, at least the larger ones, seem to be standing by Government prices on standard No. 8 coal, but the smaller ones are doing some shading. General market conditions, however, render shading a poor stimulant. Some large steam-coal users continue to "nibble" and undoubtedly would place good-sized tonnages were an attractive figure named. These tactics have not yet resulted in any business.

Ending of price fixing Feb. 1 may weaken the position of lake shippers who are figuring on holding out for the 1918 figure. So far as steam and domestic coal is concerned, little change will be felt, it is believed, so long as labor costs remain high. Breaking down of zone barriers will widen the market for No. 8 operators, while it will result in some Pocahontas coming in in competition.

Anthracite—The larger retail dealers continue to receive allotments of five to six cars a week, but domestic demand is distinctly off. Practically all that is coming into Cleveland now is being applied on long-deferred orders.

DETROIT

Slowing of activity in industrial lines, customary at the year end, and an oversupply of bituminous, tend to create a sluggish market in Detroit.

Bituminous—Neither steam nor domestic coal of the bituminous type shows much activity in the local market. Among several influences that are reflected in the market condition one is a diminished demand due to the easing off of industrial activity at the year end, which in the case of many concerns is made more pronounced by the cancellations of Government contracts for munitions and war supplies.

A condition which jobbers pronounce a more important factor in the falling away of business, is the over abundant supply of bituminous now in the reserve piles of steam plants and in the yards of retail dealers. This is the outcome of a sort of frenzied buying that took place a few weeks ago, under stimulus of the reiterated warnings that a serious shortage might be expected this winter.

These disturbing forecasts were circulated just about the time the fuel administration was calling on everyone to buy any coal that could be had, without regard to whether the stock was of a sort suitable to meet the consumer's requirements. Large shipments from Illinois and Indiana were coming into the market at that time, while the movement of West Virginia and Ohio coal was light, because of the priority rules applying to lake loading. The combination of circumstances resulted in numerous steam plants and retail dealers being overstocked with low grade coal, which in the case of some of the retailers is said to be in the form of mine run and other sizes that do not readily find a market with their customers.

Dropping temperatures this week seem to bring a brightening outlook for the retailers, as, providing the frosty weather is continued, there is likely to be a stronger demand from household consumers.

Anthracite—While efforts are being made, it is said, to obtain an increase in the city's allowance of anthracite, shipments continue in small volume. Domestic consumers dependent on base-burner heaters are being urged to put in at once the two additional tons they are allowed to receive to complete their winter supply. It is estimated there are approximately 55,000 of this class of consumers in Detroit. Any residue of anthracite remaining after they are supplied will be available to hot-air furnace users to the extent of one-half their fuel needs for the winter.

COLUMBUS

Colder weather has stimulated the retail trade to a small extent, although the full benefits have not yet developed. Steam trade is still quiet. Production is not large.

A cold wave that appeared just previous to Christmas has had the effect of stimulating the retail trade, which has been rather quiet for the past month or six weeks. Retailers have started deliveries on orders caused by the lower temperatures, and there is quite an increase in the volume of business. Retail stocks are good and the cold spell is not yet reflected on the operating and jobbing ends of the industry. Consumers are buying the fancy grades principally, as Pocahontas is now in the market. Frequent calls are also received for Ohio-mined coals. Retail prices have been shaded slightly under the influence of slow business, but many of the larger dealers are holding to the Government levels. Rural dealers are having a good trade, as farming communities did not stock as early and as liberally as urban sections.

The steam trade is quiet and probably will remain in that state for some time. Consumers are heavily stocked and are loath to buy under present conditions. Manufacturing plants are casting around to get on a peace basis, but the transition will take some time. Railroads are taking a fair tonnage, and that is the best feature of the steam trade. War plants are gradually cutting down, and their fuel requisitions are not so large as formerly. Most of the steam producers are playing a waiting game, being content to abide their time instead of trying to force trade by cutting quotations. It is realized that there is little demand and coal can not be sold to any extent by cutting prices. Some of the smaller producers, and especially those from West Virginia, are shading prices, but the effect is not felt in the trade generally.

Production is rather slow, due largely to lack of orders. Influenza is still having its effect on the output. But there is no special reason to increase the production and operators are generally loading when they have orders to fill. Cancellations, which were frequent several weeks ago, have now practically stopped and many cancelled orders are being replaced on the books. This indicates a better selling. In the Hocking Valley the output has been about 65 per cent. and in the Pomeroy Bend field about the same. In eastern Ohio the output has been slightly above 50 per cent.

CINCINNATI

Mild weather dominates the trade, demand being limited in all departments of the market. Prospects for colder weather are welcomed.

The coal trade is still under the influence of a remarkably mild season, coupled with the fact that most people, including both domestic consumers and industrial users of fuel, have enough coal to run them for a time. The most remarkably warm winter in several years has been experienced thus far, and several prospects for colder and more severe weather have passed by without making good. The consumption of fuel has accordingly been on a limited scale, so far as heating purposes are concerned, while the industrial situation also remains such as to make consumption very small, compared with a normal season.

The sudden let-up in manufacturing caused by the end of the war has not as yet given way to activity, and is not expected to do so until after the first of the year, if not a good deal later: in the meantime the business resulting from demands for immediate delivery is extremely small. Predictions of much colder weather in the near future must be realized before the coal trade will have anything much in the way of business, and the Christmas holiday, with its reduction in production, is therefore actually welcomed, instead of coming as a serious factor in limiting the available amount of fuel, as the case usually is, and was emphatically last year. Should severe weather come and last for a time, enough emergency demand is expected to stimulate business somewhat, although it is realized that really active business depends chiefly upon the industrial situation.

LOUISVILLE

Colder weather along with reduced production great aid to general market. Prices firmer, and market in generally better shape. Domestic coal showing some improvement, with almost all grades of steam draggy.

The first snow of the season struck Louisville on Christmas Day, and the retail business is showing some slight improvement as a result. However, cold weather is needed to clean up surplus stocks, and get the consumers back into the market. Consumers at the present time are so well protected that orders for the most part are for small quantities. Jobbers report a slightly better volume of inquiries, but not so much actual business. Reports of lower prices are leading to more inquiries than actual business, but the market is looking up.

With the producers the situation is somewhat easier as a result of the layoff for the Christmas holidays. Some mines are down entirely, while others are operating only 40 per cent., still others making no effort whatever to operate more than two or three days. Cars are plentiful and labor is in full supply. A number of producers are reported to be cutting prices slightly in order to secure business and are absorbing brokerage. Wagon mines and small mines without marketing facilities are reported to have cut prices as much as 50c. a ton and more, but are slowly being forced out of competition by lack of demand and the fact that tipple mines have an overproduction.

Rail coal shippers are somewhat worried over the prospects for a revival of river coal movement. Due to the fact that the pressure on West Virginia and Pittsburgh field operations has let up somewhat, it is reported that consumers in these districts are again looking up their river markets, and are planning to start shipping by water on high tides. Due to the fact that rail rates have been increased 25 per cent. by the Federal Director, and that water rates show only a small increase in operating expenses, of less than 10c. a ton when handled by big towboats, it is believed that river coal will be a big factor in the Ohio and Lower Mississippi river markets. There is a shortage of coal-carrying equipment on the Ohio which may hold back movement somewhat this season, but it is believed that with advantage in freight rates coal by river will come back strong.

General complaint is again heard concerning collections. Retailers have been having a little trouble in collecting, while the mine operators have been so anxious for business that some of them have again started shipping rather freely on open account. One large mine operator said he was voicing the opinion of a number of operators when he said "Collections are rotten."

Coke

CONNELLSVILLE

Coke control probably continues. Continued scarcity. Blast furnaces somewhat less active.

While at this writing there has been no formal announcement by the Fuel Administration as to how long it intends to continue control of coke prices, the trade in general is disposed to conclude that the Fuel Administration's policy will be the same with respect to coke as with respect to bituminous coal, so that the announcement that price control on coal will continue at least to Feb. 1 is to be taken as indicating that coke price control will also continue. If the coke operators have any feeling on this subject it is one of disappointment, as they were in hopes of some fancy prices ruling for a while if price control were taken off Dec. 31. The blast furnaces, on the other hand, are very much pleased, even those that have contracts, as they anticipated difficulty in securing contract deliveries if price control were taken off, asserting that coke operators have often yielded to the temptation to sell in the open market coke that was due on contract.

The blast furnaces are not running altogether as well as they were. While very few have actually blown out, quite a number are operating at slightly reduced rates. There is no new demand for pig iron and shipments are made up of such iron as buyers are willing to take on contract. Many buyers are seeking cancellation of contracts, but the furnaces assert that they expect all contracts to be carried out.

There is practically no furnace coke being offered in the open market, but there are fair offerings of foundry coke, and demand is lighter than it was. The market remains quotable at Government limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ⅜-in., $7.30; clean screenings, over ⅛-in., $5.50, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Dec. 21 at 288,505 tons, an increase of 4540 tons, and raw coal shipments at 206,400 tons, a decrease of 7500 tons.

Buffalo—The supply is improving, as coal is more plentiful. The situation, however, is not easy yet, and it is not likely to be immediately, due to the scarcity of help in the beehive districts. The output is increasing, though, and it will likely continue to increase. Furnaces are expected to be active, no matter if they have no war orders to fill. Hardware is so scarce here that it is difficult to buy nails or anything of the sort, and this shortage must be made up somehow. Fuel breeze coke is not finding a very ready market and the same will soon be the case with the sizes.

Middle Western

GENERAL REVIEW

No market of any kind. Industries well stocked with coal and only curtailment of production will help the coal industry to steady itself and prepare for the future.

We are practically at the beginning of the new year, and no relief, of any substantial nature, is in sight for the coal operator. The demand for coal on all sizes, either steam or domestic, is gone. The market, if it may be called such, has degenerated into purely a "weather proposition," and nothing short of a blizzard will help.

The writer recently made a trip which covered the manufacturing centers of Illinois, Indiana and Michigan. It was found that all the large steam plants had enough coal on hand to enable them to run from six to ten weeks. It is safe to say that all factories in the territory mentioned above acted on the advice of the Fuel Administration, and are in a position to run full time. It is true that there are isolated cases where there is little coal in storage, but it is also true that there are plants with enough storage coal on hand today to enable them to run steadily until the first of April.

The domestic situation, in a modified way, is about the same. Take the city of Grand Rapids, Michigan, for an example. It is estimated that there is approximately 65,000 tons of domestic coal consumed in Grand Rapids every winter. The local Fuel Administration say they have figures to show that the retail dealers have in their bins today approximately 50,000 tons of coal. The retailers say that they have little chance of selling this coal, as they stocked up their trade during the summer and fall months. From this it can be readily seen that the retailers of Grand Rapids will not purchase coal very heavily during the coming winter. A careful investigation further shows that what is true about the domestic coal situation in Grand Rapids is equally true of nearly all the towns in the Mid-West territory. It may be that some retail dealers are purchasing heavily at this time, but these cases are rare enough to be the exception that proves the rule. There is one oft repeated factor that will no doubt help matters, and that is the average householder has his bins filled with Illinois or Indiana coal, which burns much faster and with less resulting heat than the higher grades of eastern coal.

There is no doubt about the fact that what ails the coal industry today is overproduction. The factors which brought about this condition are too well known to go into at this time. It is pretty generally conceded by the operators that there is only one cure for the trouble at present hindering the industry, and that cure is a decrease in production either to be brought about by the operators themselves, or through action on the part of the Fuel Administration. At all events, it will be a beneficial thing if some strong influence is brought to bear in order to steady conditions in the industry until such time as the reconstruction program is well under way, when it will be possible for the industry to look into the future and prepare itself for further developments.

CHICAGO

News that eastern coal is to be kept out of local market pleased dealers. Anthracite situation puzzling. Many dealers have plenty of hard coal, while others have none. Little anthracite being delivered to consumers.

The news that the present zones were not to be abolished for some time came to the Illinois and Indiana operators, as well as the retail dealers of Chicago, a few days ago, and brought with it a decided feeling of relief.

The operators were pleased by the information, because they were assured that Chicago, one of the few remaining localities where coal is sold, would continue to be open to them. The dealers were pleased because they now have an opportunity to dispose of their surplus stock of Illinois and Indiana coal. If eastern coal had been allowed on the market, it is very probable that serious difficulties would be encountered in disposing of the Indiana and Illinois coals to the public. It is only fair to state, however, that it is a debatable question if eastern coal ever wins back its old position in Chicago. Many people and firms who heretofore would use only eastern coal, and who, through various conditions have been forced to burn Illinois and Indiana products, like these coals so well that the eastern fuels will probably never displace them.

The anthracite situation continues to be an affair of many angles—so many that few people understand it, even the local Fuel Administration. It appears that some dealers have plenty of it in their bins, while others have none. It doesn't make much difference, however, because those with it are bound by so many rules, restrictions, regulations and other things, dear to the heart of the local Fuel Administration, that there is no opportunity for them to move it from their bins.

MILWAUKEE

Colder weather and snow promise to liven up a dejected market. Anthracite and coke prices reduced by the fuel administration, owing to a shading of dock charges.

The coal market ruled unusually quiet all through the month of December, because of the mildness of the weather, but Christmas week brought snow and a blizzard, which, if it continues, will inject "pep" into the situation. The last run of anthracite cargoes has been unloaded, but there are still some cargoes of soft coal afloat. Receipts of anthracite by rail continue to a moderate extent.

Following closely after the raise of 90c. per ton on all grades of anthracite except

buckwheat, noted last week, came an edict from the same source making a reduction in the retail price of anthracite of 25c. per ton and cutting coke 50c. per ton. The drop in the price of anthracite was due to the fact that dock companies have been restricted to a charge of 50c. per ton for loading wagons and trucks. Formerly they were allowed 75c. Wagon dealers are accorded a margin of profit of $1.75, and wholesalers $2.25. The new ruling put the large and small dealer on the same footing in regard to retail prices. Anthracite delivered at the curb is now worth $12.52 for nut, $12.21 for egg, $12.43 for stove and $11.05 for pea. The maximum price that can be charged for carrying in coal is 50c. per ton. Coke is now $11.50 carried into bins, as against the former price of $12.

ST. LOUIS

A dragging market continues. Weather conditions bring better prospects. No domestic or steam demand to speak of. Car supply good, transportation getting slow. General situation seems to be slightly improved, with prospects fairly good.

The local market is still heavy and slow. The cold weather that started on the 24th helped a little, and business always is slow during the holidays. The light snow that followed on the 26th and 27th was the first of the season, and it was not of a nature that helped the situation at all.

Domestic demand is poor. As a matter of fact, there is scarcely any domestic coal moving except into the poorer sections of the city, the residents of which usually live from hand to mouth.

Steam business at the last part of the year is always slow, firms preferring not to spend any more money than they have to at the close of the year and usually depending upon their storage supply to get through the last week or ten days. That, of course, has held the movement up, but everything indicates a better tone to the market in the near future and operators and retailers are looking forward to some splendid business periods during January and February, and possibly into March. The railroads have not bought as heavily recently as they were expected to, and they will likely soon come in for a good tonnage.

In the Standard field the situation is still in bad shape. Some mines have been down entirely for as long as a week at a time, and others are running on one and two days a week. Screenings are exceptionally hard to move, and some companies have as many as 100 cars of screenings unbilled, being able to move lump in a pinch. However, other mines have a surplus of lump sizes on hand, and there does not seem to be any systematic method of equalizing the distribution of the different sizes from the field as a whole. If it were permissible, and the authority were delegated to some association or individual capable of keeping clean and free from entanglements, a pool of the Standard field would be the only method whereby any efficiency would enter into the distribution plan at all. Some operators sell all lump and no screenings, and others sell all screenings and no lump, as a result all the mines are idle and a lot of coal is given away below cost for the lack of a proper selling or distributing agency.

There is some dissatisfaction at different places in the Standard field among the men from lack of work, etc., but it is expected to gradually disappear with a better demand.

The railroad tonnage from the Standard field is fairly good, but not what the operators would like or what they expect. It is good enough, however, to keep several mines going on fairly decent working time.

In the Mt. Olive field conditions are much better than those in the Standard field. The demand for this coal, which is of higher grade, is better throughout the north and west, and a heavy tonnage seems to be going to Chicago. Working time is good, and the railroad tonnage from this section is also heavy, so that in a general way the Mt. Olive field presents a somewhat satisfactory situation.

In the Carterville field in Williamson and Franklin Counties, and also in the Duquoin field, the conditions have improved in the last few days. While there is a surplus of coal in these fields, orders seem to have come in for shipment to the north in better volume. In a general way the situation has improved. Cars are somewhat short in some places and transportation is not all that it could be, even in the few days prior to the recent snow; but taken as a whole, the situation in these fields is entirely satisfactory. There seems to be no trouble anywhere, and while some mines are not getting all the working time they want, a general feeling of satisfaction ushers in the New Year in these districts. The railroad tonnage from these fields is also heavy and has helped to maintain the market conditions.

In the St. Louis market Standard 2-in. lump is still selling anywhere from $1.50 to $1.80, with Standard egg and nut at about the same price. Mt. Olive is as low as $1.65, and 6-in. lump from $1.75 to $2.00, with screenings at from $1.20 to $1.50.

There has been no cut in the Mt. Olive prices to speak of, and only here and there has anything been done in the way of cutting Carterville prices; and that was usually on restricted equipment or on off-grade coal.

There is no change in the domestic prices in St. Louis and at the close of the year they are as follows:

Carterville lump	$5.75
Mt. Olive lump	5.25
Standard lump	5.00

The Government price per net ton f.o.b. mines, with the exceptions above noted is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1	3.05@3.20	3.05@3.20	.....
No. 2	3.05@3.20	3.05@3.20	.....
No. 3	3.05@3.20	3.05@3.20	.....
Mine Run	2.35@2.50	2.35@2.50	2.20@2.30
Screenings	2.17@2.32	2.17@1.32	1.50@1.60

Special preparation on Carterville is 10 cents extra. Williamson & Franklin Co. rate is $1.10. Other fields 95 cents.

General Statistics

Directors of the Pond Creek Coal Co. have declared a dividend for the quarter of 37½c. a share, payable Jan. 1 to stock of record Dec. 27. Since July 2, 1917, Pond Creek has been paying 50c. each quarter, so that the present declaration is equivalent to a cut from a $2 to $1.50 annual basis.

LOADINGS OF BUNKER COAL DURING OCTOBER, 1918

Bunker coal laden on vessels engaged in the foreign trade, according to the Bureau of Foreign and Domestic Commerce, is as follows for each of the customs districts specified:

Districts	Gross Tons
Maryland	31,713
New York	231,894
Philadelphia	21,661
Virginia	64,473
Total	349,741

BALTIMORE & OHIO

Following is a statement of coal and coke tonnage moved over the Baltimore & Ohio system and affiliated lines during the month of August, 1918, as compared with the corresponding month of the previous year:

	1918, Tons	1917, Tons
Coal	4,658,226	3,165,568
Coke	219,126	295,917
Total	4,877,352	3,461,485

Exports of Anthracite and Bituminous Coal and Coke, by Customs Districts and Countries, During October, 1918

COAL AGE

Volume 15 New York, January 9, 1919 Number 2

Is it Opportunity or Crisis?

BY FLOYD W. PARSONS

ONE-SIXTH the area of France has been devastated. The territory destroyed included the richest districts in the country. Approximately 350,000 French homes were utterly ruined. From 70 to 90 per cent. of France's steel, sugar and weaving industries no longer exist. The machinery has either been demolished or carried away. One-fifteenth of the population of the Republic is dead or missing.

France must be restored. So must other areas that have suffered the ravages of war. Rapidity of execution is the primary consideration in this matter of reconstruction. Almost everything is needed, and in large quantities. Where can the necessary supplies be obtained most readily?

The United States Army has on hand enough lumber to build 100,000 small houses. It has millions of dollars' worth of plumbing, heating, water-supply and sanitary fixtures. It has bakeries that will produce 2,000,000 loaves of bread daily. From the demolition of war plants America will be able to salvage astounding quantities of useful material and equipment.

What is more sensible than that the United States dispose of these supplies in the regions desolated by war. Setting aside all impulses of human sympathy, there are material reasons for such action. Practically all supplies have but a limited ability to resist rust and corrosion, and it is commonly agreed that to sell such materials now in our domestic market would seriously curtail the Nation's normal production at a moment when we are trying to find employment for 5,000,000 soldiers and munition workers.

We are building a great merchant marine. To fill these ships we must secure foreign markets. Such work is slow and expensive. Here we have a chance to satisfy our humanitarian ideals, establish a foreign trade and help overcome the danger of a domestic labor panic. It is not important that we be paid for these things immediately. The debts Europe already owes us cannot be settled unless America proceeds at once to make France, Belgium, Serbia and Russia self-supporting. The chief security for our loans is the recuperative power of the Allies. The food we send them only makes the debt larger. It is the acres of land and factories we restore for production that enhances our security and hastens repayment.

Let us say to France right now: "Here is the material for reconstruction, and if you say the word, we will also furnish you an unexcelled engineering organization to start the work while your people are getting on their feet once again." If we will do this, there will be no doubt in Europe as to our sincerity in the matter of international agreements that will forever end war.

America faced war unitedly. Let us not face peace irresolutely. Already in our midst we hear the prophets of woe. Theorists talk of bread lines and panics that will accompany the deflation of our industries. Our practical men who deal in facts know better. They are aware that industry can slow down if skilfully managed, without disturbing the relation of wages and cost of living.

The workman must now think of increasing his individual production, and the employer will not have to think of decreasing wages. Let us grow up to inflation by establishing new profits which labor can share. The world's needs were undersupplied before the war, and now with the coming of peace we are minus the labor of 15,000,000 workmen, killed or disabled. It will be a generation before the common wants of humanity can be supplied on a pre-war basis.

We must talk more of increasing production and less of liquidating wages. America occupies a new place in the world. The cure for domestic inflation is foreign trade. We have a splendid chance to begin our expansion right now.

This is a time of opportunity, not of crisis.

Changes in Beehive Coke Oven Construction Due to Mechanical Operation

By GEORGE W. HARRIS
Editorial Staff, *Coal Age*

FIG. 1. PULLING COKE AND FORKING IT BY HAND

THE Yankee is reputed to be one of the laziest of fellows. At least such a statement about his countrymen was said to have been made by the late George Westinghouse, at a dinner given in his honor in London, England, a number of years ago. The further comment was offered, by way of explanation, that if the Yankee was given a piece of work to perform involving hard manual labor, he lost little time in devising some mechanical device that would do the work for him.

Numerous instances are on record of devices that have supplanted almost entirely the human element in industrial operations. A striking case of this kind is at hand in connection with coke plants. For many years coke has been drawn from beehive coke ovens and forked onto cars by hand. It has been such a familiar sight that it requires no special comment (see Fig. 1). The physical effort of drawing coke from an oven with the ordinary coke puller is not excessive in itself, but the discomfort caused by the heat from the oven and the recently quenched coke adds greatly to the labor of this operation during hot weather. However, it takes considerable time to draw an oven by hand and the oven is losing valuable heat during the operation.

There is always an incentive to supplant hand labor by a mechanical device that will do the same work quicker and cheaper. The advantages of such an arrangement are most apparent during strikes or at times of labor scarcity. It is of added benefit to a plant to be able to accomplish with a few men and a machine what would ordinarily require several times the ordinary labor force to do by hand. Also, by drawing an oven by mechanical means coke costs are reduced and the output of the oven increased. Probably such considerations as these largely influenced and hastened the working out of a mechanical coke-drawing and loading machine.

The most extensively used machine of this type—the Covington, made by the Covington Machine Co., of Covington, Va.—is shown in Figs. 2 and 3 operating at a beehive coke plant of the H. C. Frick Coke Co. This machine consists of two principal parts, an extractor for drawing the coke out of the ovens and a conveyor for screening and loading it into cars. The steel ram used to extract the coke is carried in a swinging carriage so as to reach either side of the oven. These mechanical features of the Covington are the result of a gradual growth, the necessary changes being made in the ovens as modifications of the old beehive type became desirable.

The type of mechanical extractor used, and its action, brought about changes in oven door width, the oven brick liners, door jambs and coke yard details. The old oven door was too narrow to permit of operating the ram to best advantage, so it was widened

to a width of about 42 in. or more. The brick in the lower course of liners, which frequently received the impact of the ram of the coke extractor, were found to be rather light to withstand the hard usage they received and accordingly were made larger and heavier. Similarly, the door jambs were modified to better meet the new requirements imposed upon them. Substantial construction is required in the lowest jamb to resist the wearing action of the ram bar in its travel in and out of the oven.

The changes noted were the essential ones, and were brought about by failure of the oven parts under the more severe service of the mechanical extractor over that of the old hand coke puller. Such parts simply needed to be made heavier, of different shape or of other material. When the new method of coke extraction was thoroughly established other changes were made in old ovens, as repairs or renewals permitted their adoption with little additional expense. When new coke plants were contemplated further modifications were possible; these greatly reduced the cost of the plant and at the same time permitted the same or an increased efficiency in oven operation. Among such improvements is the abandonment of the wide, elevated coke yard with its retaining wall and the lowering of the oven itself in the same proportion.

The accompanying illustrations bring out these points. In Fig. 4 is shown a cross-section of a typical old-time beehive block, or double row, coke-oven plant with its elevated ovens and yards necessitating considerable dry wall for oven foundation and yard retaining walls. Contrast the old type with the machine-operated plant shown in cross-section in Fig. 2. One of the most apparent and striking changes is the lowering of the whole plant. Cut off some 7 to 8 ft. of the lower part of the oven foundations and yard in the plant shown in Fig. 4, and the new type as illustrated in Fig. 2 will be had.

New machine oven plants can be constructed flat on the ground—no high foundations for ovens are necessary, no yard retaining walls are required and little filling. The grades for the yard and machine tracks

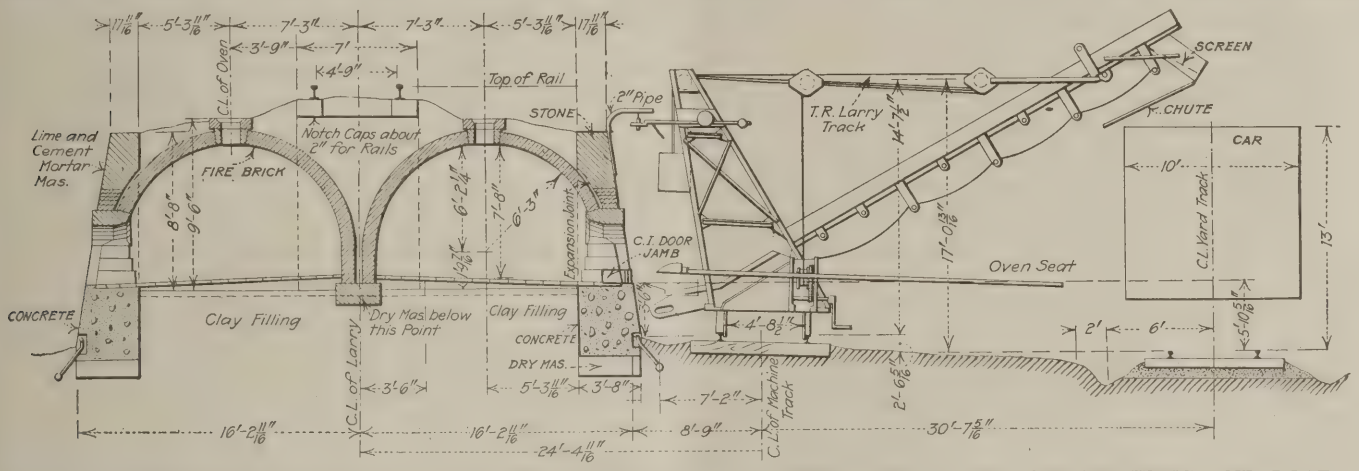

FIG. 2. CROSS-SECTION OF BLOCK COKE OVEN ADAPTED TO MACHINE OPERATION—COKE-DRAWING AND LOADING MACHINE SHOWN IN POSITION

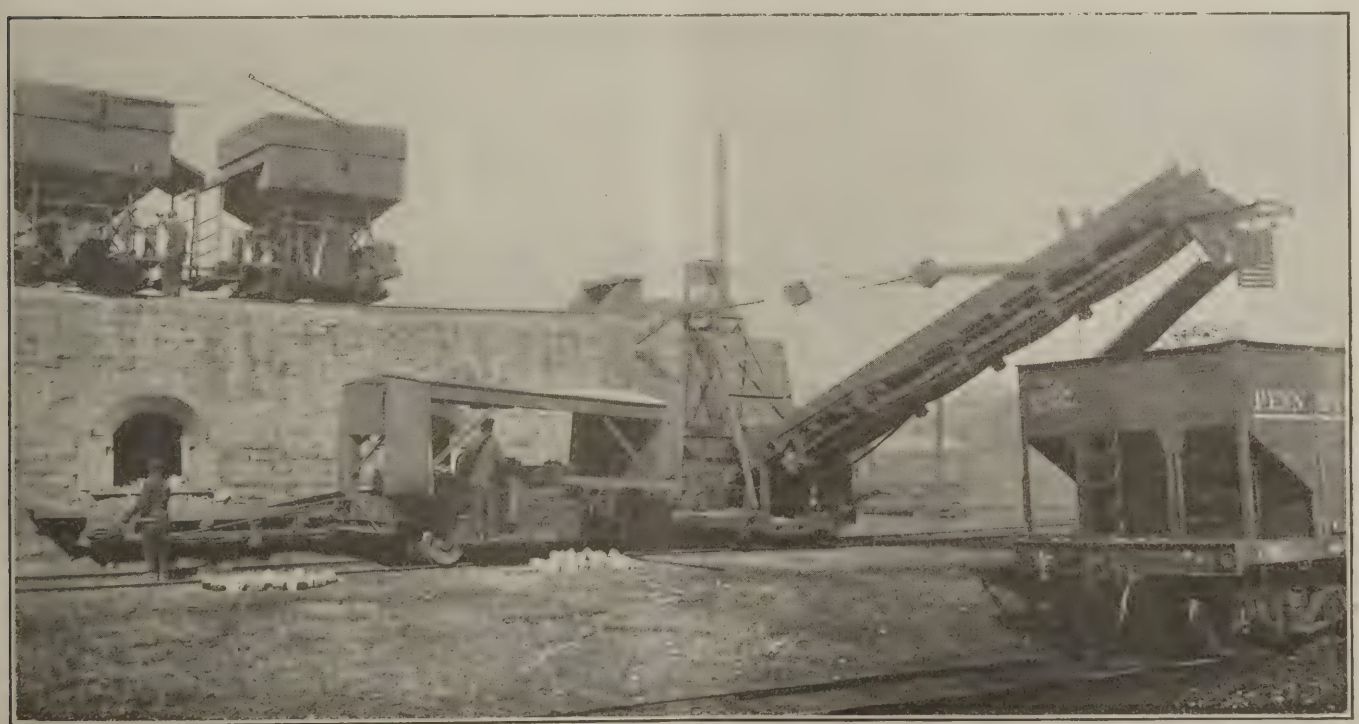

FIG. 3. COVINGTON COKE-DRAWING AND LOADING MACHINE OPERATING AT A PLANT OF THE FRICK COKE CO. IN WESTERN PENNSYLVANIA

are practically on the same level. Furthermore, the height of the bottom of the oven above the machine track has been reduced; the old height was 3 ft. 6 in., now it can be 2 ft. 7½ in. This lower oven represents quite a saving in cost of construction. Attention is also directed to the distance of the yard track from the coke oven; this is practically fixed by the length of the coke-loading apparatus and is a minimum distance. Some old coke yards are twice

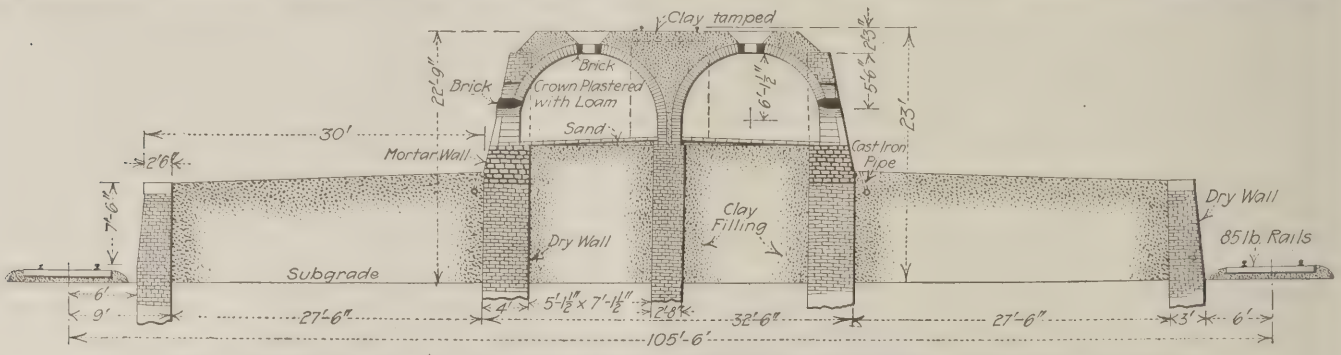

FIG. 4. CROSS-SECTION OF OLD-TYPE BLOCK BEEHIVE COKE OVENS, OPERATED BY HAND

the width of those shown in Figs. 2 and 3. In the machine-operated oven yard, storage room for coke is not a consideration; generally the coke is on cars for shipment before it has entirely lost its heat.

The largest beehive coke-oven operator in the country is the H. C. Frick Coke Co., of western Pennsylvania, a subsidiary of the United States Steel Corporation.

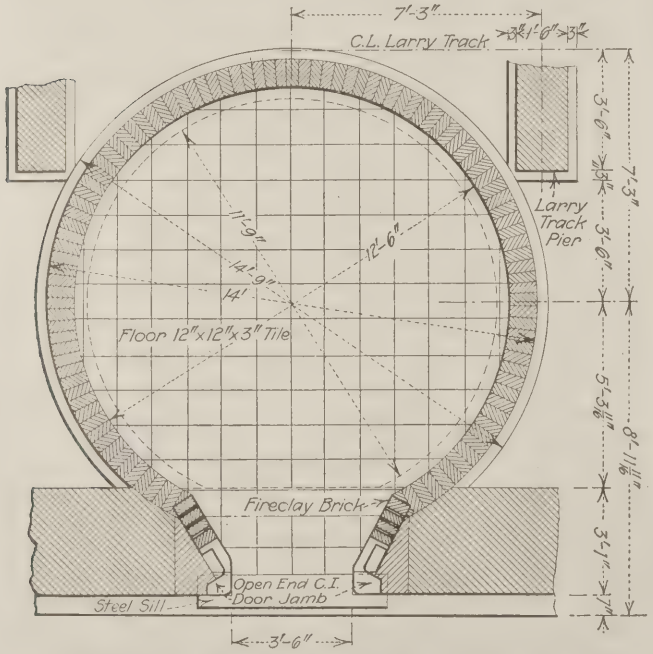

FIG. 5. PLAN OF COKE OVEN SHOWING FRICK JAMB DETAILS

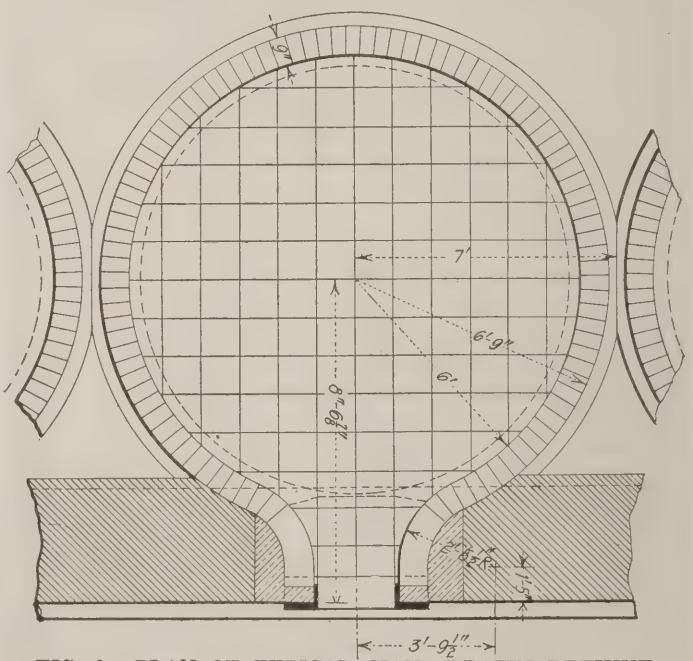

FIG. 6. PLAN OF TYPICAL, HAND-DRAWN BEEHIVE COKE OVEN

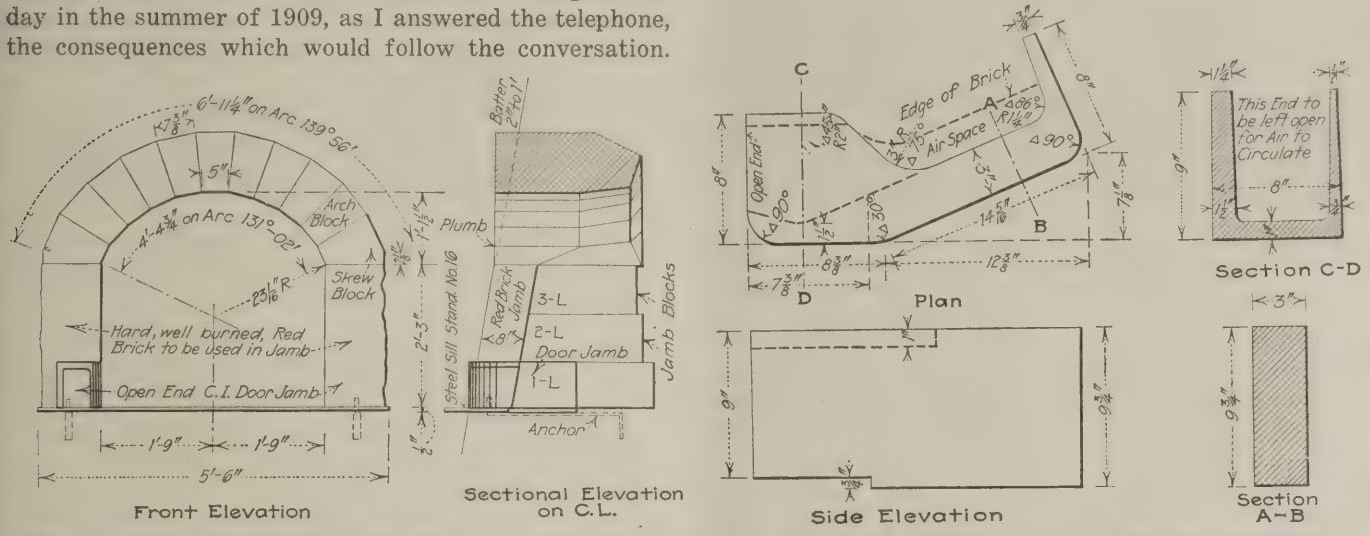
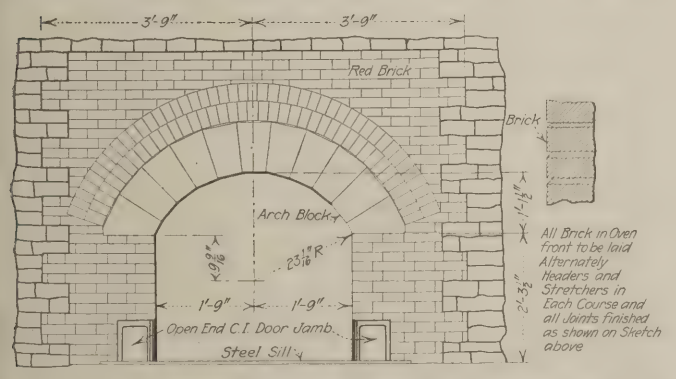


This company operates some 19,000 ovens and has installed over 80 Covington machines at its coke plants. Furthermore, the methods used by this concern are of more than ordinary interest to those operating beehive ovens, as the practice of the Frick people today represents the mature judgment of many years of experience in coke manufacture. In Figs. 5 to 10 inclusive are shown details of the present Frick method of construction for machine-drawn ovens. Where this company is rebuilding or repairing its old ovens (no new ovens of this type are being constructed by the Frick company) concrete is used in the front wall from a point 6 in. below the yard level to the oven seat. From the oven seat to the top of the wall mortar masonry is used, the mortar being composed of sand, lime and cement. The proportion of lime and cement varies somewhat in the different parts of the wall. On the portion of the wall over the door, where the greatest heat is encountered, about one-third cement and two-thirds lime are used; but in the rest of the wall about equal proportions of lime and cement are employed.

There has been no change in the Frick method of constructing the foundations or in the plan of tamping clay filling under the ovens. Neither has there been any change in the method of constructing the ring dry-wall under the ovens in either the bank or the block type. Dry-wall is used for the foundation to a point within 6 in. of the brick wall, the top 6 in. of this wall being constructed of mortar masonry.

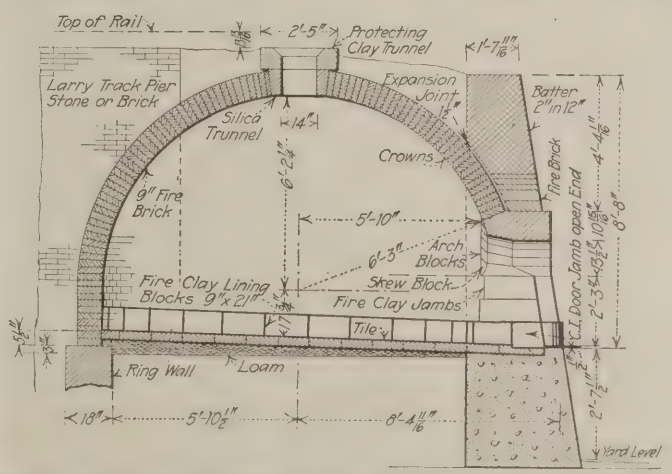
Due to the abrasion of the coke and extractor bar on the lowest jamb, the Frick people are now replacing this jamb with an open-end cast-iron jamb, as indicated in Figs. 5, 7, and 9, and as shown in detail in Fig. 8. The cast-iron jamb has an open outer end in order that there may be a free passage of cool air back of the metal exposed to the greatest heat from the oven.



On account of excessive wear on the bottom courses of the ordinary lining brick, these are now being replaced with lining-blocks 9 in. high and 21 in. long; they are heavier than the usual liners and are not so subject to damage when accidentally struck by the scraper head of the machine.

In connection with the straight jambs on either side and directly back of the oven door there is an interesting bit of history, which is best told in the words of G. W. Greenwood, treasurer of the United Refractories Co., of Uniontown, Penn.: "Little did I imagine one day in the summer of 1909, as I answered the telephone, the consequences which would follow the conversation.

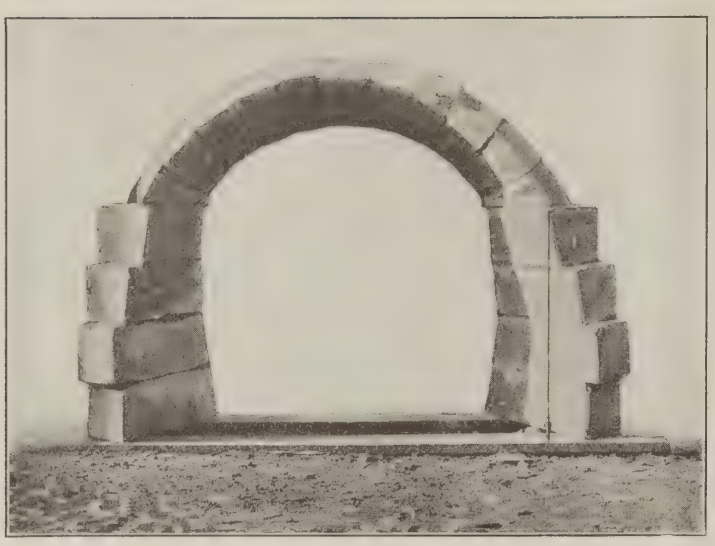
FIGS. 7 AND 8. ELEVATION AND SECTION OF STANDARD FRICK BEEHIVE DOORWAY FOR MACHINE-OPERATED OVEN AND STANDARD CAST-IRON DOOR JAMB



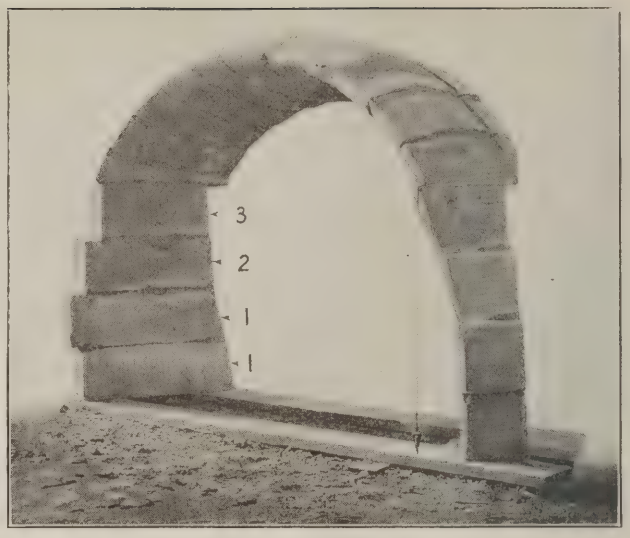
The call was from a wide-awake, progressive superintendent of a coke plant not far from Uniontown, who wished to discuss with someone the possibility of making brick and shapes which would simplify the drawing of coke by machines. Now, in the original type of beehive coke oven—a hemispherical dome with an opening at the top for the escape of fire and smoke—there is also a short entrance arched over, like the passageway into an Esquimo's snow-built home. The plan

at the floor of the oven is somewhat like the bottle-shaped opening shown in Fig. 6.

"It will readily be seen that the coke on each side of the door cannot be drawn so readily, as it has to be pulled around the corner formed by the reverse curve. So long as the drawing was done by hand, this difficulty apparently received little consideration. But with the introduction of machines, it was found impracticable to clean out the oven completely, the scraper of the coke-drawing machine not being like the gun which was warranted to shoot around the corner. So it was asked if the plan of the oven could be modified to allow direct access to all parts of it. At the same time there was the necessity of preserving the bottle-neck shape of the front opening on account of the arch which covers it. Accordingly, a representative of the United Refractories Co. and the superintendent who brought up the subject together worked out a compromise by which the opening at the floor of the oven is like that shown in Fig. 5, while at the base of the arch which covers the opening a horizontal section of the oven resembles Fig. 6.



"The arch is supported on each side by jamb blocks, which up to 1909 or 1910 had always been made with a curved face. The plan worked out was to use one or more straight jambs for the lower course or courses



FIGS. 9 AND 10. DETAILS OF OVEN FRONT AND DOORWAY AND SECTION THROUGH STANDARD FRICK OVEN

on each side of the doorway; the next course of jambs being straight on the lower edge and the face developing so that the upper edge was slightly curved. Next the top course of jambs began with the flare of the course immediately below, at the top having a more decided flare, conforming to the base of the arch and making a firm support for it.

"The success of the plan was apparent from the start. The height to the base of the arch (springing line of the arch) is either 29 in. where three jambs

FIGS. 11 AND 12. SETS OF JAMBS AND ARCHES ERECTED IN THE OPEN TO FORM A DOORWAY
Fig. 11—View of doorway from a point in the oven and directly behind the arch. Fig. 12—View of doorway from a point in the rear and to the right, looking obliquely through the doorway

are used on each side or 38 in. in the case of four jambs. In the latter case two No. 1 jambs are first used on each side (being superimposed), each jamb being approximately 9 in. in height; the odd 2 in. in the total height being supplied by the skews. The arches are placed on the top pair of jambs so that they project about 9 in. in front of the top jambs. These details are shown in Figs. 7 and 9. The front overhang of the end of the arch brick is to permit the use of red brick on either side of the door, as shown in Fig. 7. The width of the oven door determines the position of the front ends of the jambs; they are swung as far apart as necessary in the back to fit in with the liners of the ring wall of the ovens. The divergence in each particular case is determined by the diameter of the oven and the length of the neck. This construction tends to eliminate the inaccessible pockets on either side of the oven.

"In Fig. 11 the arrangement of the jambs and arch bricks (erected in the open) is shown as viewed from the standpoint of a person in an oven looking out through the doorway from a position directly behind the arch. A plumb-bob is shown suspended from the base of the arch to the ground; from the position of the bob one can see how the top jamb overhangs like a precipice. Also, it can be seen in Fig. 12 that there is a beeline from the feet of the observer right through the lowest jamb on the right of the doorway. This view was taken from the rear, and to the right, looking obliquely through the doorway, so as to show the overhanging (side overhang) No. 2 and No. 3 jambs.

"Recently there has arisen the feeling that all the advantages in drawing coke should not be reserved for the machines. It is felt that where the drawing is done by hand, the men should also have a straight pull and not be obliged to draw coke around the corner. As a result the so-called straight jambs for machine ovens are being used also for hand-drawn ovens, the only difference being that they are set closer together on account of the narrower door. These jambs have been favorably received in the field, particularly by large operators in the western Pennsylvania region."

The business-like precision of mechanically operated coke plants catches the eye of a person visiting the works of progressive coke men. The yards of such plants at times may even suggest a temporary cessation of work, as the business of drawing and charging ovens is attended to with dispatch and such operations may be completed by noon, giving an air of idleness to the plants. It has been said, "It looks like Sunday at the ovens." The darky coke puller is fast disappearing too. He may still be a picturesque sight in the eyes of some, but not to the practical coke manufacturer of today. Officials of the Frick Coke Co. and the United Refractories Co. (leading sources of such information) furnished the data, photographs and prints for this article.

Reservation of Superior Coking Coal Is Considered by British Committee

In the report of the Carbonization Committee of Great Britain special note is made of certain seams of coal in the celebrated Durham field of England, which have been exported as steam coal; this coal is particularly adapted to the manufacture of coke, forming a fine, hard coke, low in ash and sulphur. The report states that these seams should be reserved exclusively for this purpose and on no account should the export of this particular quality of coal be permitted; the export of coals capable of producing a good quality of metallurgical coke must of necessity in time be a disadvantage to the expansion and economy of the iron and steel trade of Great Britain.

An increased foreign demand for the best coking coals is predicted by the Committee in the near future as some of the countries which produce relatively small quantities of iron and steel are making plans for increasing their output and coke ovens will be included in their schemes. Even if it is found upon investigation that there is a sufficiently large reserve of coking coals to meet the needs of the increasing home iron and steel industry, nevertheless every effort should be made to export any surplus available for such purposes, as metallurgical coke; it should be exported in that form in order to retain the valuable byproducts at home.

Some Tests with Flow Meters

By JOSEPH A. MAGUIRE
Schenectady, N. Y.

SYNOPSIS—*In order to increase plant efficiency actual facts must be known. The flow meter furnishes means for readily obtaining the actual consumption or output of a steam generating or consuming apparatus. The tests here described resulted in the elimination of wastes that were unsuspected.*

PRESENT world conditions, necessitating conservation of all resources, have brought to a deserved prominence many pieces of apparatus heretofore incorrectly looked upon as luxuries. Some years ago the flow meter was in this class, but of late power plants in all industries have been straining to their utmost in an endeavor to raise efficiencies and, consequently, the real value of this device has been gradually realized.

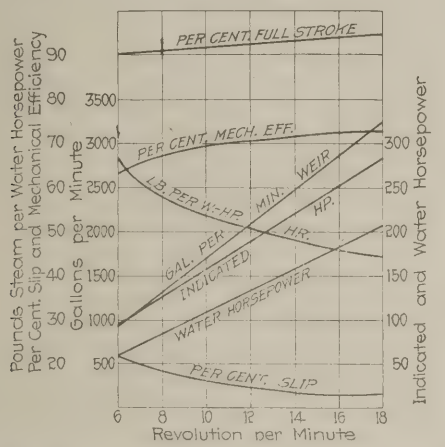


FIG. 1. CHARACTERISTIC CURVE OF DUPLEX COMPOUND CONDENSING PUMP

Steam end, 19 x 36 x 36 in.; water end, 21 x 36 in.; head, 248 ft.; suction, 10 ft.; steam pressure, 125-140 lb.; Scranton jet condenser vacuum, 22-24 in. Steam curve includes losses in 1460 ft. of 8 in. main and 68 ft. of 5 in. main

A considerable amount of prominence has been given to the use of the flow meter in boiler rooms of manufacturing industries, central stations, etc., but its application to mine power plants is practically an untouched subject. The present article is an account of operations in this field.

A short time ago a number of collieries operating 36 boiler and power plants were thoroughly investigated by their owners and engineers. These men had foreseen the coming coal shortage and were preparing to meet it not only through increased production but by conservation in their own plants. Flow meters were installed as a means of obtaining the required information.

The testing equipment, at the start, consisted of four Type F flow meters, the necessary mechanisms and an assortment of nozzle plugs and pipe reducers. Later eight more meters of the same kind were added.

After a preliminary survey of the entire layout it was evident that the pumping situation was the most serious and needed immediate attention. The first pumping plant investigated, located 250 ft. underground, consisted of four simple duplex direct-acting non-condensing pumps, each of 2000 gal. per minute rated capacity, and two duplex compound condensing pumps, each of 4000 gal. per minute capacity. The condensing pumps were equipped with low vacuum jet condensers. These six pumps were located in three adjoining pump-rooms, two of which were partially submerged during periods of high water.

Steam was supplied from a modern boiler plant on the surface, at a distance of 2500 ft. The steam main was a 10-in. pipe for a distance of 600 ft., then branching to two 8-in. mains to the pumps. Bypass connections at the pumps allowed any set of pumps to be operated from either 8-in. line, and connections at the foot of the borehole, where the 10-in. pipe branched, allowed either 8-in. pipe to be supplied from an old boiler plant.

It was decided that the required information could best be obtained by determining the characteristic curves of the various pumps separately and in combination. For this purpose three meters were installed on the steam lines to the pumps. A double end contracted weir was built on the surface to measure the discharge of the pumps, and engine indicators were used to determine the indicated horsepower, mean effective pressure, length of stroke, etc.

One of the three meters was connected on the surface to the 10-in. steam line. The other two were located inside the mines, on the 8-in. lines, 1600 ft. from the pumps. Each instrument had a calorimeter and recording pressure gage connected nearby. In order to meet accurately the wide range of flow necessary for the tests, one of the meters inside was connected to two nozzle plugs, one an 8-in. and the other an 8 x 5½-in. reducer.

In order to get the meters installed it was necessary to load them in mine cars, lower them down a slope to a gangway, haul them by mule to the airway where they were to be installed and finally carry them to the points chosen for their location. There the meters were unpacked, assembled and adjusted.

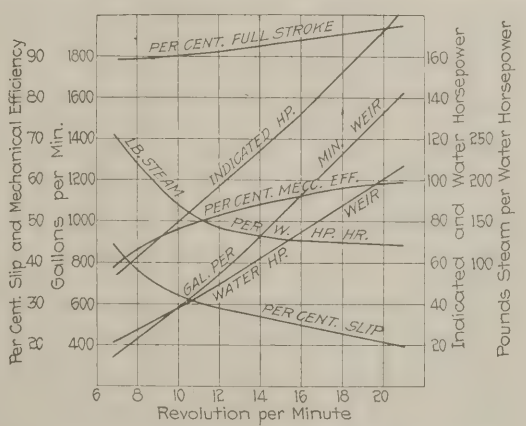

FIG. 2. CHARACTERISTIC CURVE OF DUPLEX NON-CONDENSING PUMP

Steam end, 24 x 36 in.; water end, 14 x 36 in.; head, 254 ft.; suction, 6 ft.; steam pressure, 125-134 lb.

The accompanying curves are some of those taken during this investigation. Fig. 1 was taken from tests

on a duplex compound condensing pump and Fig. 2 from a test on a duplex noncondensing pump. These tests, it should be borne in mind, were taken after the pumps had been installed several years. The steam consumption curves also include condensation losses in pipe, etc. The tests were made with the steam lines and pumps in the condition in which they were found and as ordinarily operated. They were in fairly good repair.

An analysis of the curves showed several important facts. The difference in steam consumption per water-horsepower between the compound condensing pumps and the simple noncondensing pumps was particularly noticeable. It was, of course, recognized that one type was more efficient than the other, but the large difference in economy was more easily seen by obtaining definite figures under similar operating conditions. This one item has been of much value in numerous other pumping installations, since it emphasized the facts in a way that no estimated figures have been able to do.

Another point demonstrated by the test was the lack of capacity of the pumps. The condensing pumps were rated at 4000 gal. per minute at 22 r.p.m., but they could not be safely operated above 3000 gal. per minute. Their best operating capacity from a standpoint of repairs and upkeep was at 1700 to 2000 gal. per minute, while their best efficiency was obtained at about 3500 to 4000 gal. per minute, a rating at which they could not be operated. This not only explained the difficulty experienced in caring for floods but also showed a wastage of about 3000 tons of coal per year due to the necessity of using the noncondensing pumps even in low-water periods.

As a result of these tests two 2500 gal. per minute electrically driven centrifugal pumps have been installed and have effected a fuel saving of about 4500 tons of coal per year. In addition, and of equal importance, is the fact that production is not now curtailed during periods of high water.

It might be interesting to note that the totals of the two inside flow meters checked within 2 per cent. of the meter on the outside 10-in. main.

After the foregoing tests had been completed a series of boiler and power-plant tests were carried out. The primary purpose of these trials was to determine power costs, boiler-plant efficiencies and, in the case of the generating plants, efficiency from coal pile to switchboard.

The size of the boiler plants varied from 1500 to 4000 hp. and the electric plants from 1400 to 3000 kv.-a. For these tests, platform scales were used for weighing the coal. Flow meters were installed on individual boilers and on the distributing steam mains. Other equipment included feed water flow meters, draft gages, recording pressure gages, flue gas thermometers, Orsat analyzer, electrical instruments, etc. The plant tests were of one week duration. Individual boiler tests of 25 hours were made, checking a flow meter against the feed water measured in calibrated tanks.

Types of Boilers That Underwent Tests

The types of boilers tested were horizontal return tubular B. & W., Stirling and Wickes. The furnaces were of the Dutch oven type, with sloping 18 per cent. air space dumping grates. Steam jet blowers furnished forced draft in the smaller plants and engine-driven fans in the larger ones. The fuel was a mixture of No. 1 buckwheat and birdseye anthracite containing 10 per cent. moisture and 15 per cent ash. The conditions, from a metering standpoint, were often difficult because of low velocity and pulsating flow. Nevertheless, the average error was seldom over 2 per cent. and in only one instance 10 per cent.

From the standpoint of the engineers and helpers making the test the conditions were equally trying. Boiler-room temperatures varied from 125 deg. F. down to 10 deg. Meters on steam mains, although filled with a strong alcohol solution, frequently froze. Those mounted on boilers did actually freeze occasionally, and at times draft gage and Orsat readings were only pos-

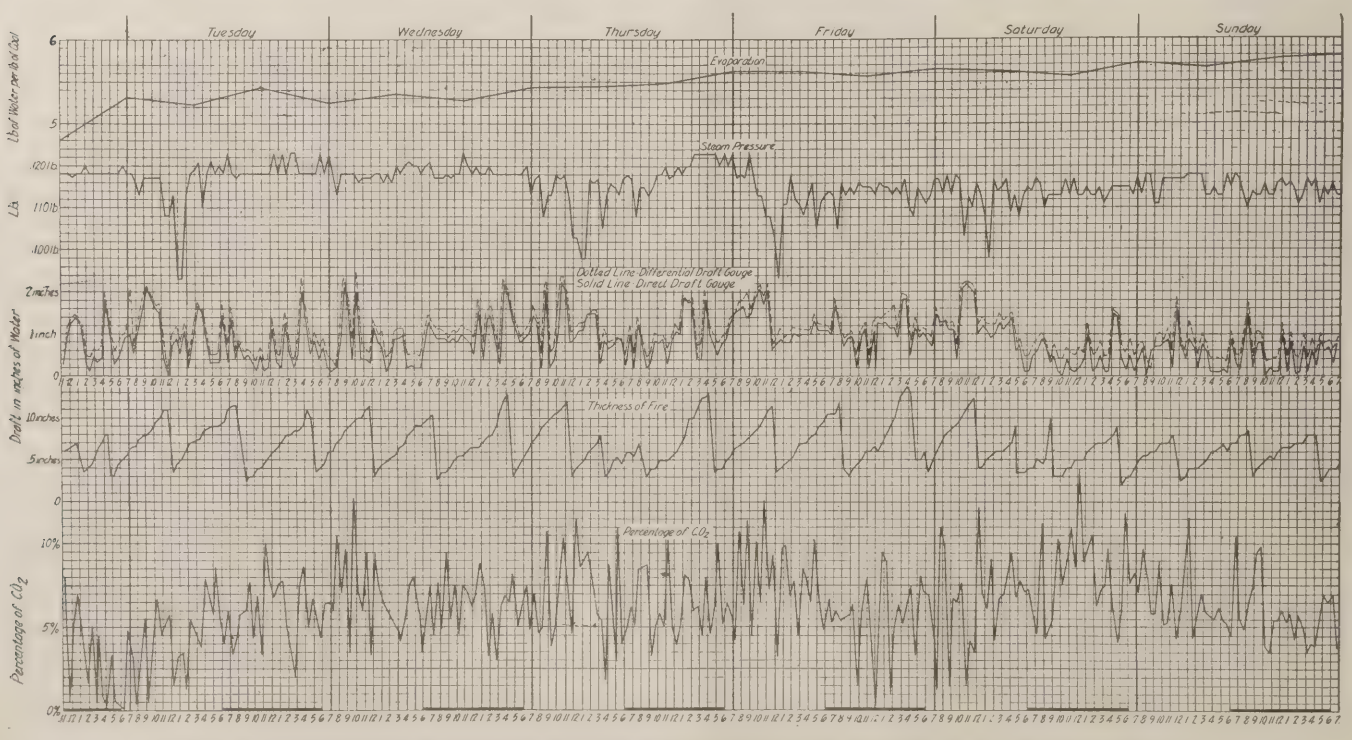

FIG. 3. EVAPORATION OF ONE BOILER FROM READINGS TAKEN IN A SIX-DAY TEST

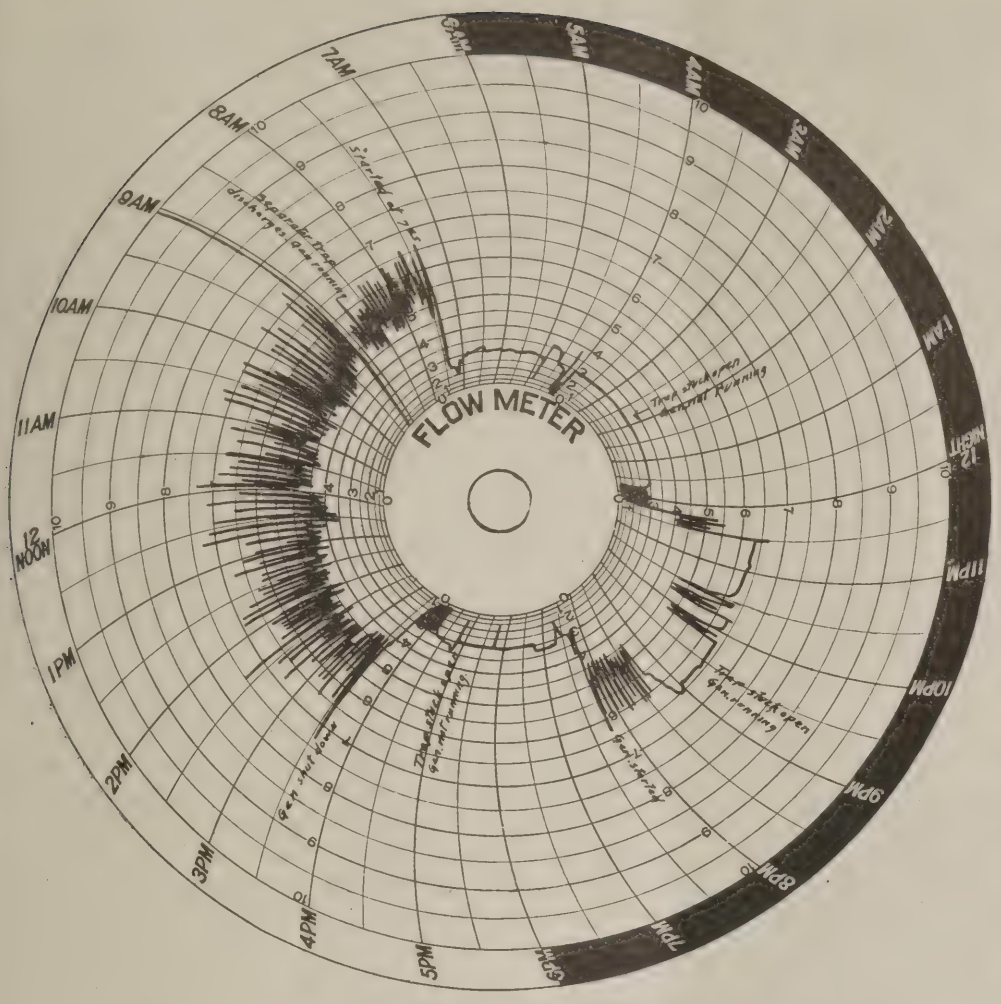

FIG. 4. A 24-HOUR FLOW METER CHART

sible by building fires on old grate bars directly under the instruments.

Power costs and distribution ratios were determined from the flow meters. The boiler units showed a general lack of capacity and a low efficiency; an average of 125 per cent. rating was the best the most modern plants could develop.

The curves shown in Fig. 3 indicate the evaporation of one boiler plotted from readings taken during a plant test of six days. The boiler was a 270-hp. Stirling. The test was made without instruction or otherwise interfering with the usual operation of the plant, the object being to obtain, as nearly as possible, the usual operating conditions.

In view of the extreme care taken to secure normal operating conditions, the rise in the evaporation curve from 4.8 lb. of water per pound of coal as fired to 5.8 at the end of the test is of interest. This curve gives an excellent illustration of the value of checking results. The increase in evaporation was due entirely to the firemen bettering their efforts as they realized they were being investigated.

Fig. 4 shows a flow meter chart taken in one of these tests. The meter was placed on the line supplying a 300-kw. compound noncondensing Corliss engine driving an alternator. The high momentary demand lines with the engine shut down and with it running should be noted. An investigation disclosed the fact that the trap on the boiler-room header was out of order. The water from the header had been going to the engine separator and was thence discharged by the trap, causing the lines on the chart referred to above. It showed also that the separator traps frequently stuck open, allowing a steam wastage of 100,000 lb. per 24 hours. Repairing the traps remedied this trouble.

In addition to disclosing a condition that might have wrecked the engines eventually, had the separator traps failed to open, it was figured that the stopping of steam waste would pay for all the meters in one month's operation. After the results of these tests had been fully tabulated and analyzed, certain recommendations were made to the owners, one of which was the replacement of 15,000 sq.ft. of grate surface by new grates of smaller air space and the addition of 10 mechanical stokers. The 2500-kv.-a. mixed pressure turbines will also be installed later.

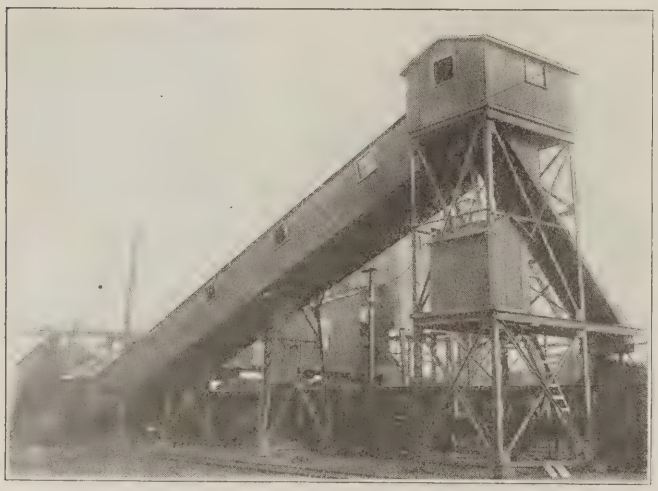
The foregoing tests, and the benefits which will accrue from them in the way of increased efficiency and fuel saving, represent a phase of engineering work in which the flow meter finds its rightful place. In many power plants there are actions going on or equipment improperly functioning which will finally make themselves evident; but in many of the cases these discoveries are made only after considerable damage has been done. It is in such instances that these meters prove themselves a valuable aid.

Peat Plays Important Part in Relieving Coal Shortage in France

Coal substitutes are being used in France, owing to the fuel shortage. Among such substitutes peat offers large inducements for exploitation; it is found over large areas of France. Mixtures of peat with other fuels have proved satisfactory. In one instance a mixture of six tons of fresh peat, one ton of sawdust and one ton of coal dust and factory waste was tried. A binder of wet peat is added in the mixing machine and the resulting briquets are left to dry until they contain no more than 30 per cent. moisture.

These peat briquets are used in France for firing boilers. At one locality trials with varying proportions of peat and coal have been conducted on a large scale, the maximum amount of peat so used being 90 per cent., the proportion depending somewhat on the amount of moisture in the peat. Investigations are also being carried on at the present time looking to the feasibility of utilizing peat as fuel for gas producers, and for supplying gas for gas engines.

Coal Crushing Installation at an Illinois Mine



By W. G. Kimball
Staunton, Ill.

When it became necessary to increase the crushing capacity at No. 2 mine of the Mt. Olive and Staunton Coal Co., at Staunton, Ill., the experience gained from the first crusher installation was utilized. This showed the following points were desirable, if not absolutely necessary, for a successful coal-mine crushing plant:

1. That the change from normal loading to crushing, and back, be simple and quick; that only lump sizes of coal be fed to the crusher; that the flow of coal be regular; and that it be possible to instantly stop this flow.

2. That the crusher and coal-handling machinery should be able to handle, without damage to itself, props and ties and other foreign material such as lifting jacks and rail plates.

3. That the discharge pit and other places liable to collect quantities of coal should be capable of easy cleaning.

SURFACE PLANT OF MT. OLIVE AND STAUNTON COMPANY

4. That the machinery be as free as possible from liability to breakdowns and consist of standard parts capable of repair at the mine shop, or easily obtainable from any supply house stocks; and that the power supply be continuous.

The new crusher was accordingly located at the end of the shaker screen, being fed by an extension from the main screen, receiving its motion from it when the connecting-rods are in place. To make this connection requires from ½- to 2-min. stop of the main hoist. This is all the time that is necessary to change from normal loading to crushing or *vice versa*.

An American ring coal crusher was chosen as fulfilling the crushing requirements and indicating a low cost for maintaining the crushing surfaces. A 125-hp. General Electric motor was direct-connected by flexible coupling to the crusher, both being mounted on a structural iron subframe, built 10 ft. wide, in order to span the belt pit.

Despite the large ground space required by a belt conveyor and the high cost of the frame structure, the belt conveyor was chosen in preference to a bucket elevator, as the belt only required a pit 5 ft. deep against 13 ft. for the elevator. Furthermore, the belt could handle a mine prop without damage to itself. A 42-in. Stevenson-Adamson belt conveyor was accordingly installed on a heavy frame made by the American Bridge Company.

The railroad car-loading chute is arranged so that a bar screen may be installed, allowing separation of the crushed product into nut and slack. The nut will be carried by a second conveyor across the slack-loading track to a nut-loading track. This has not yet been found necessary, as the normal supply of nut coal obtained from the tipple is sufficient. This was not true when crushing mine-run coal.

A 100-kw. generator is arranged to run the crusher and elevator motors on a circuit entirely separate from the rest of the mine, thus reducing the chance of losing the power and filling the crusher pit and crusher with coal. With the former installation, this form of accident sometimes required four hours to clean up—the spaces being so small that all the coal had to be moved with the hands.

While the crushing apparatus is in operation a man stationed at the side of the feeder shaker watches for foreign matter in the coal. He has the shaker-engine control wire at hand and stops the shaker in case of trouble, or on signal from the yard.

As it was not feasible or considered necessary to construct a hopper to allow car changing, and as it is bad practice to stop the belt under load, only the shaker feed is stopped. This makes it necessary for the yard foreman to give the stop signal about half a minute before his car is filled out, and the start signal as much later as he judges the change will take. It is interesting to note the precision with which this is done, the coal stream from the chute dwindling away to nothing just as the car is filled and starting with full force as the new car rolls into place. No hoisting time is lost.

The coal sizing as obtained with the crusher set for 1¼ in. is identical with the 1¼-in. slack from the mine, it being difficult to find the line marking the change in a car partly filled under the tipple and finished out with crushed coal.

The equipment was designed to convert all the lump and nut coal that the mine could hoist (375 tons per hour) into slack. It has been tested up to 3000 tons per hour without reaching the limit of capacity. At this rate about 90 hp. was required for the crusher and 15 hp. for the elevator.

Use of Colliery Waste Heaps

The *Zeitschrift für angewandte Chemie*, in its Sept. 13, 1918, issue states that it is well known that carbon dioxide is an active agent in the nutrition of plants when applied under suitable conditions. Carbon is gradually converted into carbon dioxide when added to the soil in a finely divided state. The chemical change is brought about more effectively when lime is mixed with the carbon. A recent German patent suggests the use of a mixture of coal dust and lime as a substitute for some of the artificial manures now become scarce. Large quantities of one of these materials exist in the waste heaps in the neighborhood of the collieries.

Effect of Steam Blowers on Combustion

By W. D. OWENS
West Pittston, Penn.

THE use of steam in any form of jet blower diminishes the recoverable heat content of the coal consumed. For instance, it was stated in a recent issue of *Coal Age* that it required 11.61 lb. of air theoretically to convert 1 lb. of carbon into CO_2. It was also stated that about one-half more air must be added for practical purposes, and many plants are using twice as much. Therefore, practically at least, it requires 17.41 lb. of air to pass through the furnace for every pound of coal consumed.

It was also shown in the article referred to that 8.94 lb. of nitrogen is isolated upon the union of oxygen from the air and carbon, and this nitrogen is of no value whatsoever. Now, since 17.41 lb. of air is necessary, 11.61 lb. is directly concerned in the combustion, leaving 5.80 of unaltered atmospheric air going through the flues. Hence, we have as the product of ordinary furnace combustion 2.67 lb. of oxygen plus 1 lb. carbon plus 8.94 lb. nitrogen and 5.80 lb. of common air, making a total of 18.41 lb. The specific heat of carbon dioxide is 0.217, that of nitrogen 0.245 and that of common air 0.2375. The average of these in the proportion of their densities and percentages is 0.2368. Assuming that the fuel will produce about 13,000 B.t.u., the temperature in the furnace developed by the burning of 1 lb. of this coal will be:

$$\frac{13{,}000}{18.41 \times 0.2368} = 3000 \; deg. \; F.$$

If, now, we assume that a steam blower is installed which injects 4 per cent. of steam into the necessary quantity of air (and it must be remembered that the quantity of air cannot be lessened upon the addition of steam into it), and we will have $18.41 \times 0.04 = 0.7364 + 18.41 = 19.1464$ lb. of air and steam going through the flues. Now since the specific heat of steam is equal to 0.48 (and indeed it cools off so rapidly before entering the grate that its specific heat becomes nearly that of water itself), we have as follows:

$$\frac{13{,}000}{19.1464 \times 0.2559} = 2653 \; deg. \; F.$$

It was found in the first calculation that without the use of steam the temperature of the gases should be about 3000 deg. F. Therefore, a decrease of 347 deg. F. when steam is mixed with the draft, means a loss of about $\frac{437}{3000} = 11.5$ per cent. in the heating capacity or the evaporative power of the boiler.

Of course, the advocates of steam blowers may argue that the steam, when entering the ashpit, and mixing with the air, is the means of raising the temperature of the whole volume of air before it passes through the grate bars, and hence raising the temperature of the whole atmospheric volume going through the flues. This is true, and plenty of experiments have been conducted to find to what extent the temperature is raised when about 5 per cent. of steam is mixed with the draft. The results average about 65 deg. F. Therefore, there is no valid objection to deducting this from the result of the foregoing calculation. Thus $347 - 65 = 282$ deg. and $\frac{822}{3000} = 9.4$ per cent. of loss. In addition to the foregoing the steam taken from the boilers to operate a "steam blower" so as to produce the draft, lessens the practical operative horsepower of the boiler about 10 per cent. more. Thus, in the aforesaid calculation, it was found that 4 per cent. of steam furnished in a volume of air, one-half more than that theoretically necessary, amounted in weight to 0.7364 lb. of steam furnished for every pound of coal consumed. If we now take the average evaporative power of coal to be about 6½ lb. of water, we are losing when using steam for steam blowers about $\frac{0.7364}{6.5} = 11.3$ per cent. of the capacity of the boiler plant. Therefore, between the loss of power caused by the steam passing through the fireboxes and the quantity of steam taken away from the boilers through the steam blowers, we have $9 + 11 = 20$ per cent. of the power of the boiler plant that is consumed in its own operation.

The presentation of the facts in this form should seriously impress upon the minds of every foreman in charge of a boiler plant the great amount of power wasted and dividends lost, to the company, when steam is thus used carelessly. It should also convince him that no steam whatsoever should be mixed with the air draft of any boiler plant, unless the quality of the coal is such that this must be done in order to prevent serious trouble and expense from the effect of clinkers.

I have heard the remark upon several occasions, from men well educated, that the steam from steam blowers, passing through the fire grates into the furnace, is a source of considerable increase in the temperature of the gases in the combustion chamber. I am sure, however, that if they had given the subject any serious consideration they would think themselves rather ridiculous. The reason for this claim is, of course, that steam in passing through the fire is disintegrated into its original gases—oxygen and hydrogen—and that on the recombination of these gases to again form water, the temperature is raised to a point somewhat above 5000 deg. F., this being the temperature realized in the oxy-hydrogen blow pipe.

It is not necessary to say a single word upon the absurdity of such a possibility. How can disintegration and reunion take place through the medium of heat and be accompanied by an evolution of heat?

The only points that can be advanced in favor of using a steam blower are: (1) That the steam issuing from such a blower into an ashpit raises the temperature of the air before it enters the fire, and therefore the ultimate temperature of combustion is to that degree higher than it would have been without the steam. (2) The steam mingling with the air keeps the bottom layer of fuel resting upon the bars moist, and hence prevents clinkers from adhering to the grate, and walls (if the coal contains sufficient iron pyrites to cause such trouble). Furthermore in keeping the material loose, it also aids in preserving an air passage open through the bars.

Sociological Work Accomplished by the Consolidation Coal Company

THE slogan appearing in each issue of the *Mutual Monthly Magazine,* which is published by the Consolidation Coal Co., reads: "Our interests being identical, we work together for our common good—employer and employed." This announcement is an indication of the spirit with which this prominent miner and shipper of coal approaches problems connected with its employees. The Consolidation has over 10,000 names on its payroll, and has established what it calls an Employment Relationship Department. This department looks into the health, education, amusement, recreation and other matters connected with the mining population about the company's various plants. The stars on the service flag of the company number 1174, about 10 per cent. of the employees having joined the colors.

The work of the Employment Relationship Department is most interesting. Possibly the health of the employees and of their families is given the first consideration. A force of 44 doctors and 13 trained nurses attend directly to this matter in the different divisions of the company, and their skill is reflected by the good health conditions of the mining towns under their charge. Registered trained nurses who have had more or less training in town and country practice were secured, though they must have had at least one year's practical experience before entering the employment of the company. In selecting the nurses, personality as well as education, training and experience were taken into consideration. Their duties are numerous and varied, and their work most exacting and trying; diplomacy, tact, knowledge, experience and untiring effort, combined with a pleasing personality, are among the necessary qualities they must possess in order to insure success in their work.

The nurses work with the doctors under the general supervision of Director C. L. Green, of the Employment Relationship Department, but are subject to the orders of the division managers so far as their duties pertain to local matters of discipline and the policy of the company. The general scope of their work, general activities and so on, are outlined by Director Green, to whom weekly reports are submitted. These reports show considerable activity on the part of these nurses during the year 1917, as the following formidable list indicates:

Nursing visits	7499	Office cases	1485
Instructive visits	6770	School cases	56
Social visits	6498	School examinations (medical)	373
Miscellaneous visits	561	School talks	235
Home visits—school cases	237	Meetings attended	71
Field cases	1468	Dressings	1259

In addition to the duties connected directly with health work, these nurses engage in general community and playground work, kindergarten activities and domestic science instruction; they also conduct safety and first-aid classes among the children, and visit the schools, where they give health and first-aid talks and demonstrations. They visit the healthy as well as the sick, and are always prominent in local Red Cross and relief work. Furthermore, they have organized Junior Boy Scout companies and sewing circles. At the community houses they meet with the women of the mining towns and instruct them in knitting, sewing and cooking. They also teach hygiene and report on the sanitary conditions of the mining towns.

FIG. 2. SCHOOL BUILDING AT JENKINS, KY.

The importance of this work can hardly be overestimated, and these nurses would be sorely missed were they to be withdrawn from their sphere of usefulness. In some sections access to the various communities in which they work is facilitated by modern methods of travel, but in the Kentucky divisions in winter it may be quite another matter—quite different from the enjoyable horseback ride in "the good old summer time," as shown in Fig. 1.

An admirable system of nursing has been worked out by Mr. Green and one that is producing good results. A nurse is placed in charge of a district and is given general instructions only; she is held responsible for her work and given full latitude as to the methods to

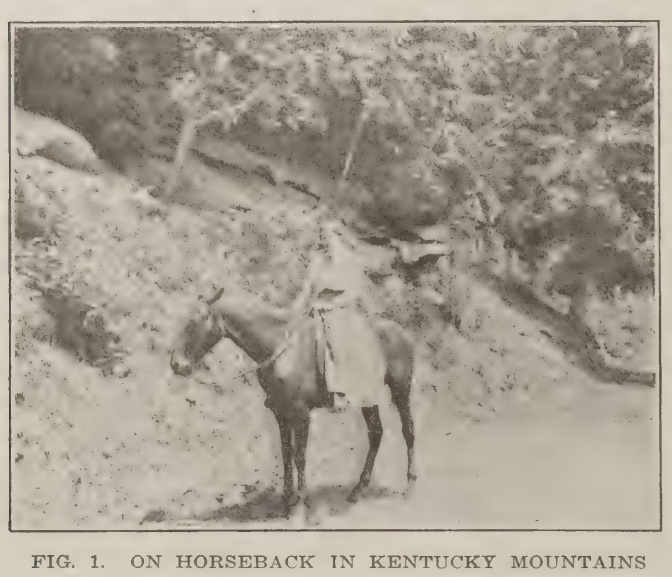


FIG. 1. ON HORSEBACK IN KENTUCKY MOUNTAINS

FIG. 3. INTERESTING GROUP OF YOUNGSTERS IN THE KINDERGARTEN CLASS—CHILDREN OF CONSOLIDATION EMPLOYEES

be used in accomplishing the results desired. The nurses feel this responsibility and respond to the confidence placed in them, seeming to be more inclined to offer suggestions as to improvements in methods of doing their work than they would be when acting under detailed orders and subject to much supervision. Mr. Green expressed himself enthusiastically about the present corps of nurses, commenting especially on the willingness they showed in assisting to combat the poliomyelitis epidemic at Monogah, W. Va., during the summer of 1917.

The hospitals of the company in the various divisions are said to have been operated with great success from a medical point of view. New hospital units were built during the year 1917[1] and others are under construction. Among those completed are a hospital in the Pennsylvania division at Gray and two in the Miller's Creek division (Kentucky), one of which is a small emergency hospital room. The men in the Maryland division, Pennsylvania division (in part) and West Virginia division are cared for in state hospitals.

[1]See *Coal Age*, page 543, March 23, 1918, for view of Consolidation hospital at Jenkins, Kentucky.

The activities of the Employment Relationship Department along educational lines are quite comprehensive and include the following: Coöperative work with public schools; kindergarten work done by the company; domestic science work done by the company; general educational work relating to hygiene, sanitation and so on. The company assists the public schools with money, school plots and in the building of schools, supplements teachers' salaries in order to secure a higher class of instructors, assigns visiting nurses to give safety and first-aid talks and demonstrations, awards prizes for the best-kept school grounds during vacation periods, and promotes other similar activities.

Among the fine up-to-date school buildings in the vicinity of the mines of the company is the school at Jenkins, Ky., shown in Fig. 2. Others of a similar character are being built, and all the schools are furnished with the most modern equipment obtainable. The kindergarten work carried on by the company's teachers begins with the ending of the regular school term and continues until the opening of the public schools in the fall. Excellent results have been obtained through this work, and great interest is always shown by the chil-

FIG. 6. MINER'S HOME IN THE MARYLAND DIVISION

dren and by their parents. There is an excellent field for kindergarten enthusiasts at the mining villages, and nowhere should more marked results follow a successful teacher's efforts. Carried on at a time when the regular schools are not in session, its activities follow along lines advocated by many leading educators. One of these kindergarten classes is shown in Fig. 3.

Domestic science instruction is also furnished by the company's teachers during the vacation period, children as well as adults being given instruction in cooking, general housekeeping and sewing. These teachers sometimes occupy one of the miner's five-room houses when a community house is not available, in which event the upstairs rooms are used as living quarters and the first floor is thrown into one large room. In addition to the regular domestic science work, this room is also used by Red Cross, Little Mothers' League, Camp Fire Girls, Boy Scouts and similar organizations. In the domestic science work, plain cooking of the foods within the reach of the population at the mines is taught and the foods are cooked with the same fuel as that used at the homes. At the time the instruction in preparing foods was given it had to do with those materials which were regarded as non-essentials to the war; it included demonstrations in the use of corn, rye, barley and other grains used as substitutes for wheat flour.

In general educational work relating to hygiene, sanitation and so on, is included the work done by the visiting nurses at the homes of the employees, in the recreation buildings and in the community houses. This work is carried on throughout the year and consists of get-together meetings, lectures, talks, cooking demonstrations and sewing and knitting classes. All these activities seem to be beneficial and productive of good general results, as they create interest in the locality and tend to stabilize labor.

Recreation and relaxation of employees are provided by the Consolidation company in the shape of indoor amusements and theatricals, outdoor directed amusements and playground work and outdoor undirected amusements. An outdoor playground is shown in Fig. 4. The physical director is on hand for any of the indoor amusements or sports carried on in the various recreation buildings and which consist principally of billiards, bowling and basket ball. The recreation buildings are twelve in number, three being in use in

FIG. 7. A CONSOLIDATION PARK AT JENKINS, KY.; OFFICE AND RECREATION BUILDINGS ON LEFT

West Virginia and nine in Kentucky. In the latter state, at all but one location, these buildings are in duplicate—one for the white and another one for the colored element of the population.

Permanent recreation buildings are planned to replace the three structures in West Virginia, as these are temporary in character, and a fourth building is under consideration. Another building is also planned for the Pennsylvania division. Those mining towns near large centers of population are in a different class from those villages remote from large towns. Under the latter class come the mining towns of Kentucky; here four of the recreation buildings in the Elkhorn division of the company have auditoriums where high-class pic-

FIG. 8. JENKINS (KY.) BAND—ALL EMPLOYEES OF THE CONSOLIDATION COAL COMPANY

ture plays (the best that can be secured) and other theatricals are given.

In Fig. 4 is shown the manner in which the Consolidation company has beautified the grounds in the vicinity of the office building and the recreation hall (on the left) and the hospital (on the hillside to the right) at Jenkins, Ky. The recreation building for the white population at McRoberts, Ky., is illustrated in Fig. 5. For the same reason that auditorium facilities are necessary in Kentucky, the recreation buildings planned for the isolated sections in the West Virginia division will also have provision for the giving of both theatricals and moving picture shows.

A physical director guides those participating in outdoor amusements and playground work. Tennis courts and baseball diamonds have been provided by the company. The men about the mines appreciate the facilities for sport and congregate on the recreation grounds after work. During the summer of 1917, two male and two female physical directors were employed to good advantage. Baseball is the popular outdoor amusement of the men, the inter-division games and the games with outside industrial teams being played to large audiences of interested "fans." The teams are fully uniformed and equipped, this at their own expense. The Ida May (Mine No. 87) baseball team, which made such a fine record during the past season, is shown in Fig. 9. Mine No. 87 is the recent shaft development of the company, near Fairmont, W. Va. A band has been organized among the Consolidation employees at Jenkins, Ky., and their playing doubtless contributes to the pleasure of those living in that section, judging from the group shown in Fig. 8.

The Employment Relationship Department is particularly active as regards publicity matters. In December, 1917, the first number of the Consolidation Coal Co.'s *Mutual Monthly Magazine* was published by this department, and it was decided to issue this magazine regularly, between 10,000 and 11,000 copies being printed each month. The entire expense of publishing and distributing the magazine is borne by the company.

The Consolidation company, through the medium of its monthly magazine and printed circulars, endeavors to present timely information to the miners and their families. Each payday a different circular is handed to the men; these are made so attractive that the recipients almost invariably take them home. The information in the circulars is

FIG. 9. BASEBALL TEAM OF THE IDA MAY MINE, NEAR FAIRMONT, W. VA.

intended to interest in turn the miners and the various members of their families—the women and the children about the mines.

The monthly magazine touches on a variety of topics and endeavors to reach the men from every angle. Interesting sketches are published of prominent men connected with the company, or others deserving of special mention, or maybe a description of some interesting piece of work about the mines. Popular interest is maintained in this family paper by printing all interesting personal items about the employees and their families. The various activities encouraged and directed

by the Employment Relationship Department are all regularly commented upon and accompanied by numerous illustrations.

Every encouragement is given to the population about the mines to cultivate gardens—they greatly improve the appearance of the house lots and have a decidedly practical bearing as contributing most acceptable supplies for the housekeeper. Prizes were offered for vegetables only during the season just ended, and no men on the monthly payroll were eligible for garden prizes. Due to the urgent need for home production of food products, especial attention was given to vegetable gardening, the object being to have the largest possible crops raised on the ground available for cultivation.

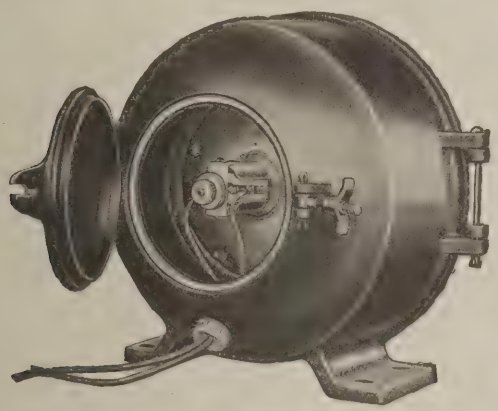
Considerable enthusiasm was aroused by the company's garden policy. For example, in the West Virginia division of the Consolidation, three cash prizes were offered to each of ten groups of mines in addition to the division or regional prizes. Thus the group first, second and third prizes were $15, $10 and $5 respectively, the corresponding division prizes being $35, $25 and $15—a total of $370 and 33 prizes in this division alone. In judging the gardens for awarding the prizes, variety, arrangement of vegetables planted and condition in which the garden was kept counted 50 points; quantity of vegetables planted as compared with the ground available made up the remaining 50 points. In judging, surrounding circumstances such as condition of the soil and local obstacles met with in making a garden were considered, as well as the number in a family who could work in the garden. At the end of the season after the prizes had been awarded, further prominence was given the matter by publishing illustrations of the successful competitors and also views of their gardens. This was an additional incentive to excel, for few fail to appreciate publicity—a deserved compliment after a season of toil, in many cases at odd hours after the regular work of the day was over.

FIG. 10. GARDEN WHICH TOOK SECOND PRIZE IN THE WEST VIRGINIA DIVISION

In Fig. 10 is shown the garden which received the second prize in the West Virginia division for the year 1918; those who were responsible for the success of this garden are also shown. The illustration brings out nicely some of the benefits derived from a cultivation of the ground around the homes of the miners. A further instance of what can be done in the way of making the home surroundings attractive by planting shrubs, vines and flowers about the house—and then caring for them—is also shown in this illustration.

Among the activities encouraged by the Employment Relationship Department community work stands out prominently. There would seem to be few sections of the country in which the people should respond quicker to this influence than in the coal-mining regions. Those living in villages about the mines have some decided advantages over the scattered population in some rural districts, it is true, but frequently the landscape about coal operations is most unattractive. The miners and their families need influences which tend to take them away from thoughts of their work and their surroundings, and out of themselves—who does not for that matter, at times?

Can Holland Supply Itself with Coal?



According to the *Allgemeene Handelsblad*, the whole production of coal in Holland has considerably increased since the beginning of the war. It now appears that Holland can, though with some difficulty, provide herself with fuel without having recourse to imported coal. Before the war, about 7 million tons a year were required for Dutch consumption. Of this quantity, the Limberg mines produced at the most a third. During the war production increased by 270 tons a month. The output of brown coal has largely increased. Peat equivalent in heating power to 350,000 tons of coal was produced this year. The use of this fuel is finding favor and consumption is increasing rapidly.

On Sept. 3 the *Zeitschrift für angewandte Chemie* republish the item quoted above. In its preceding issue, however, the *Zeitschrift* had made a statement which appears somewhat at variance with the one given in the *Handelsblad*. The statement referred to is as follows: "In accordance with a recent agreement with Germany, Holland is now receiving more coal from Rhineland-Westphalia. Since the beginning of the month two railway trains have been dispatched daily from that coal-producing district to Holland, laden with 1500 tons of coal. For the present four such trains are to run daily, laden with 3000 tons. Hence some 78,000 tons a month will reach Holland by railway, so that of the total 120,000 tons agreed upon, there will be left 42,000 tons for carriage by water."

New Mine Headlight for Haulage Locomotive Use

The Electric Service Supplies Co. will shortly place on the market the type MLC-96 Golden Glow incandescent headlights for mine use. These headlights are similar in all general features to the type ML-96, except that the case instead of being drawn steel, is made of cast iron, and provide high illumination under all conditions encountered in mining service, combined with low current consumption and maintenance cost, thus offering an efficient form of headlight for haulage locomotive use.

The headlights are equipped with yellowish green mirrored glass reflectors, which are first molded to the form of a true parabola and then accurately ground, after which they are polished and silvered. The light, in striking the mirrored surface, is reflected back through the glass, and in passing through this special glass the violet and blue rays are absorbed, leaving a beam of golden-yellow light, which penetrates fog, dust and smoke to a greater extent than is possible with a white light. Furthermore, the dazzling and blinding effect of a white light is avoided. These glass reflectors, in addition to being highly efficient, are also durable, permanent, cannot tarnish or scratch, are easily cleaned and do not require polishing. Taken from any angle, they make an exceedingly efficient headlight.

REAR VIEW OF MINE HEADLIGHT

Type MLC-96 headlights, being designed especially for mine use, have the reflector and socket flexibly suspended in the case, in order to prevent the vibration of the mine locomotive from breaking the lamp filament. The case is made of cast iron, with a rear door which permits of the adjustment of the socket so as to bring the lamp filament into the exact focal point of the reflector. The reflector, with the socket and all other mechanism and spring support, is mounted in a shell that is removable through the front door, making all parts accessible for inspection or repairs.

These headlights are suitable for 56-, 72- and 94-watt concentrated filament Mazda lamps having a light center length of $2\frac{1}{16}$ in., and satisfactory results cannot be secured from any other type or size of lamp. They may be connected in series with special resistances designed for the purpose, or in series with other incandescent lamps on the locomotive, provided these lamps are of exactly the same current consumption and of the proper voltage. The headlights complete weigh approximately 25 pounds.

Legal Department

TRESPASS UPON COAL LANDS—In Maryland, where a mining company negligently encroaches upon the coal deposits of adjoining land, the aggrieved owner is entitled to recover the value of the coal at the mouth of the mine, not being limited to the value of the coal in place. This rule has not been changed, as applied to merely negligent trespasses, by the Maryland statute which declares that one who furtively or in bad faith abstracts minerals for the land of another shall be liable for the value of such minerals, without deduction on account of the expense of mining. (Maryland Court of Appeals, Monahan vs. Mt. Savage George's Creek Coal Co., 104 Atlantic Reporter, 480.)

INDIANA WORKMEN'S COMPENSATION ACT—A mine employee was not debarred of right to an award under the Indiana Workmen's Compensation Act, for loss of the sight of an eye following an injury in the course of his employment, because he failed to give the employer written notice of the injury, where it appears that the employer had actual knowledge of the fact of the injury, and where the employer's company physician assured the injured man at first that the injury would not be serious. A coal-mining company has sufficient notice of an accident to a miner if the pitboss or foreman knows of the occurrence. (Indiana Appellate Court, Candalia Coal Co. vs. Holtz, 120 Northeastern Reporter, 386.)

LIABILITY FOR ROOF FALL ACCIDENT—Where a landslide at a mine left dirt and debris on tracks leading into the mine, an employee engaged in removing the same, preparatory to timbering, was entitled to assume that the coal company had made his place of work reasonably safe. But if a fall of rock and dirt from the roof at that place was so apt to occur that a miner of ordinary prudence would not have encountered the danger, the employee assumed the risk of injury from such a fall. (Kentucky Court of Appeals, Wallace vs. Hazard Coal Co., 205 Southwestern Reporter, 692.) The Virginia statute, requiring miners to prop and secure their working places, does not apply where danger at a particular place was not of such character as to call for use of props, as determined by the mine foreman or the miner making a report of unsafe condition. A miner was not negligent in working in a place which the foreman had assured him would be made safe, and which the slate men told him had been made so. Under the Virginia statutes negligence of a mine foreman, boss, or fireboss, and their assistants, in the discharge of statutory duties, is negligence of the operator. (Virginia Supreme Court of Appeals, Keen vs. Jewell Ridge Coal Corporation, 96 Southeastern Reporter, 767.)

SURFACE RIGHTS FOR MINING PURPOSES—Mere failure of a mine owner for a long time to exercise mining rights in the surface of land does not extinguish them. A grant of ways into, over, and under a tract of land, at such points and in such manner as may be necessary and proper for the mining and marketing of the coal under it, does not limit the grantee to a single way or opening. Under such a grant, ways and openings that are appropriate, useful and convenient in the mining of the coal are legally necessary and proper. Mere inconvenience to the owner of the surface, wrought by the exercise of mining rights, does not constitute a limitation upon them. The existence of a small garden cultivated by a tenant on the surface does not prevent the owner of mining rights from exercising them at that point. A clause in a deed granting mining rights, which absolves the grantee from liability for injury to springs in the surface or destruction thereof, as an incident of the removal of the coal, justifies such injury or destruction at such time as the mine owner may see fit to take out the coal, and injury to a spring constitutes no ground for restraining mining operations. (West Virginia Supreme Court of Appeals, County Coke Co. vs. Elkins Coal and Coke Co., 96 Southeastern Reporter, 973.)

New Order Definitely Fixes Price of Household Coke

An order providing that, in localities where anthracite is obtainable, the prices to dealers of byproduct coke for distribution by them in less than carload lots or for household purposes shall not exceed the established maximum prices of gas coke sold under the same conditions, was announced Dec. 29 by the United States Fuel Administration.

The order became effective Jan. 1 and applies to prices at point of production. It was stated that its effect would be to lower the maximum prices of byproduct coke, which already is selling at less than these prices in some localities.

Another order, also effective Jan. 1, established definitely that in localities where anthracite coal is obtainable the prices to dealers of gas coke for distribution in less than carload lots or for delivery direct to consumers for household purposes shall be the same as the lowest price for a 2000-lb. ton of stove anthracite at the mines plus the lowest freight rate to the point where the coke is produced.

This order followed receipt of information that in some places the standard 2000-lb. ton of coke was being compared for price-fixing purposes with the anthracite ton of 2240-lb. and that question had been raised as to what anthracite price should be taken for comparison. The order makes it clear that for comparative purposes the ton shall be 2000 lb. of coal and coke alike, and that the lowest anthracite price in the district taking the lowest freight rate to the point of coke production is meant.

Rear Admiral Reports on Use of Coal by American Navy

During the fiscal year ended June 30, 1918, the Navy required more than 4,000,000 tons of bituminous coal. Rear Admiral McGowan, in his report to Congress, discusses various phases of the use of coal by the Navy. In part, he says:

For the fiscal year 1917, the total Navy requirements were approximately 1,200,000 gross tons; while in 1918 the tonnage required was in excess of 4,000,000 tons. Of this tonnage, delivery was taken by the Navy of about 3,500,000 tons at principal tidewater ports, the balance being distributed among smaller stations and various interior points.

The Navy's anthracite coal requirements are as yet comparatively light, being in 1918 about 70,000 tons, principally at North Atlantic ports—approximately three times more than the quantity used during the previous year.

In the distribution of the Navy's fuel requirements, it was found necessary at the beginning of the fiscal year to meet the emergency conditions at the then early period of the war to place allotments with the leading suppliers throughout the country for an equitable share of the total production, in order that the unexpected demand could be divided as far as practicable among every leading interest concerned; in doing which care was exercised to have these allotments represent, as far as possible, a proper *pro rata* of the total production from the companies involved, based upon their percentage of output, proximity to the transportation required, convenience of facilities, etc.

In doing this, the question of price to be paid received special consideration which, in the case of coal, was taken care of by prices fixed in August, under Executive announcement, adopting as the unit base at leading districts of Navy coal production the following prices: Pennsylvania, Maryland and West Virginia (Pocahontas field)—$2 per net ton or $2.24 per gross ton; West Virginia (New River district)—$2.15 per net ton or $2.408 per gross ton. This basis has since been generally increased by different Executive modifying orders advancing the prices indicated, including wage increase of $0.45 per net ton and relative advances in central Pennsylvania, Maryland and New River district, West Virginia, to correspond with the increased cost of production in those districts, developed since the adoption of the initial fixed basis; the average price during the latter half of the fiscal year being approximately $3 per gross ton at mines producing Navy coal.

In the matter of coal, the fuel problem has been largely narrowed down to the production of "Navy Standard" furnished from mines accepted for this purpose after careful inspection and tried experience and of which the total output is limited—rendering it necessary that the utmost conservation be used in this high-class coal; to which end wherever possible other high-grade coal is being used by the Navy on work of lesser importance in order that this Department may at all times closely coöperate with the pressing requirements of other military arms of the service; and the entire commercial program as a whole, in which the vital question of our transport service and assistance to the allies has not been lost sight of.

In this direct connection, it is not inappropriate to refer to the benefits secured by all concerned in the more rapid and elastic coaling of vessels through the Tidewater Coal Exchange created during the year at the principal Atlantic ports, under the operation of which it is not essential in placing loading assignments to designate the specific pier at which vessels must load; and instead all three piers at Hampton Roads—Lamberts Point, Sewalls Point and Newport News—can be employed, depending on the supply of coal on hand and open berths available at the time of vessel's readiness. The equalization of coal credits in the exchange or pool, under the rules laid down, satisfactorily takes care of the distribution between coal suppliers and mines at interest, independent of questions as to indentity of coal.

In the handling of the daily current problem, the matter of increased storage for fuel, with more rapid handling of vessel bunkering and the transfer of coal cargoes, has been given special attention. Early in the fiscal year a fixed program of increasing all facilities for the handling of

fuel was inaugurated with a view to expanding the facilities then available which were sufficient to meet peace-time needs but entirely inadequate for the rapidly increasing requirements of the Navy.

To this end, a survey has been made of the principal ports where important work is now under way that will not only very greatly increase the total storage but also the daily handling of coal and oil. This particularly includes development on a large scale at New York Harbor, Hampton Roads, Philadelphia, Boston, Baltimore, Charleston, and in fact the survey and consequent work involves every port where cargo shipments in volume are anticipated.

As an illustration of the work done, the two storage plants constructed at Hampton Roads might be cited. One of these, covering approximately fifty acres, has been constructed by the Virginian Railway Co., while the second is being erected by the Chesapeake & Ohio Railway Co.; each having a total capacity of 300,000 tons of coal, with a storing and redelivering capacity at each plant of 300 tons per hour—the former plant being served by a large cantilever gantry crane with several reloading tracks and the latter by two large locomotive cranes of special design, equipped with booms, having an effective handling radius of 102 ft.; while the facilities of both plants as to trestles, convenience of ample track and water deliveries as well as opportunity for the additional free and full use of ships' gear, are unexcelled.

In addition, at principal Atlantic ports the most modern machinery has been provided to expedite the bunkering of ships, including the installation of special elevators both ashore and afloat, enabling the expeditious coaling of any ship under the various governing conditions.

The total plans include the latest mechanical devices and equipment for the rapid and satisfactory handling of coal in all forms and for all purposes, the securing of which, under the manufacturing embargoes more or less existing, has been a complex matter, as well as the question of necessary labor not only for the new construction work but for the manning of the coaling plants as completed.

On this latter point, it has been found necessary to develop a new form of organization which has active charge of the fueling activities at each port where established. An assistant aide for supply in charge of fueling has been appointed, who is directly responsible for the bunkering of all ships and handles all details in connection with the fueling of naval vessels—with results that have already demonstrated the efficiency of the organization; ships being refueled at a minimum of time and expense. The storage of coal alone will, when completed, represent capacity of approximately 1,500,000 tons.

During the year, steps have been taken toward increasing the supply of Navy standard steaming coal, in doing which—after thorough examination and necessary tests—it has been found possible to add a number of mines to the "Navy Acceptable List." A "Supplementary List" has also been established, embracing mines producing a high grade of coal suitable for bunkering purposes on certain types of vessels, thereby conserving the highest grade bunkering coal for purposes where it is absolutely necessary.

In connection with available coal supply, it is expected that further investigation of coal mines in the Matanuska District, Alaska, now actively under way, will show that source of supply to be of substantial service; and to that end provision was made in an Act recently approved authorizing a certain expenditure in the discretion of the Secretary of the Navy for mining and handling coal in that section.

With the development of those fields, it is expected that an adequate supply of coal for west coast and mid-Pacific stations will be provided, it being hoped that the coal will prove of such quality as to make unnecessary the shipment of bituminous coal from the Eastern fields.

Elimination of certain wasteful elements in competition is said to be one of the desires of President Wilson. He is said to favor the enlargement of the Federal Trade Commission to nine members.

New Cost Report Sheets Require Much Additional Data from Operators

Much additional detail is required in the new cost report of the Federal Trade Commission. Bituminous coal producers whose output exceeds 60,000 tons annually must make returns. Last year those producing less than 100,000 tons were permitted to make out a much less detailed report. In the new report, it is required that all details of cost must be divided between labor and supplies. Information is required under the following headings, each of which has numerous subdivisions: Mining, ventilation, drainage, yardage and deadwork, stripping, haulage, tipple operation, preparation (commercial coal), power, overhead, fixed charges to mining, other charges to cost, credits to cost, selling expenses, general expenses and administration, miscellaneous income, deduction from income, sales of coal produced, departmental transfers. The following accounts are to be used in the balance sheets:

Assets—(a) Current assets: (1) Cash in bank and on hand; (2) accounts receivable—current; (3) notes receivable—current; (4) inventories, less reserve for doubtful accounts. (b) Deferred assets: (1) Insurance paid in advance; (2) taxes paid in advance; (3) royalties paid in advance; (4) stripping done in advance. (c) Intercompany accounts: (1) Accounts receivable; (2) notes receivable; (3) loans. (d) Investments: (1) Stocks of other companies; (2) bonds of other companies; (3) mortgages; (4) real estate not used in coal production. (e) Fixed assets: (1) Coal lands and ore veins held in fee; (2) buildings, (3) machinery and equipment; (4) development charges; (5) office furniture and fixtures, less reserve for depletion and depreciation. (f) Good will, leaseholds, property rights, etc.

Liabilities—(a) Current liabilities: (1) Trade accounts payable; (2) trade notes payable; (3) wages accrued. (b) Accrued liabilities: (1) taxes; (2) interest; (3) unclaimed wages. (c) Intercompany: (1) Accounts payable; (2) notes payable; (3) loans. (d) Capital stock—preferred; (e) capital stock—common; (f) bonds; (g) mortgages; (h) loans and notes payable, bank or open accounts; (i) appropriated surplus; (j) surplus.

Eastern Coal To Move to Middle West

Eastern coal has been made available to dealers and consumers in Ohio, Indiana, Illinois and Michigan, provided the approval of the state fuel administrator can be secured. The coal will move on out-of-zone permits issued by the United States Fuel Administration. Many dealers and consumers in the Middle West have disposed of their stocks of low-grade coal, and it is believed that no injustice will be done in the great majority of cases by allowing the purchase of higher grade coals. It is believed, however, that the state fuel administrator will be zealous in protecting any centers where accumulations have not been disposed of. One city, for instance, acting in full accord with the state administrator, established a pool and brought in a very large supply of the only coal that was available at that time. It will be necessary in that city for the state administrator to afford this protection for some time to come.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

In the anthracite region the mine workers are still disposed to rebel because they did not get the second war bonus for their work in the month of October which apparently they believed they were going to get up to the day on which the award was announced by Dr. Garfield. The late date at which the award was made would have made a retroactive bonus unfair unless the Fuel Administrator could have contrived a retroactive price. That he could not do.

In Illinois, where work is now scant, the mine workers want Government ownership. They say the Government would keep them working steadily despite business conditions. We commend them to confer with the munition men who are being laid off. The Government has no work for them though the industry was created by the Government. The mine workers have noted how the whilom munitioner is coming back to the mines now he is not wanted, though he refused to come back when he was wanted. But he can perform a considerable service to the nation by informing the mine workers that the Government will not and indeed cannot guarantee steady work. It buys today and refuses to buy tomorrow as its necessities require, and when the Government owns the plant it is shut down just the same when the need for the material ceases.

Up in the anthracite region Federal agents are busy trying to find why men won't work. A local correspondent well says: "The Federal agents will doubtless have a pleasant stay and the miners will lose time as before. The only cure for loss of time is dismissal, a cure which is now out of fashion. In the Schuylkill field where no one is allowed to work a breast unless assisted by another man the tardy workers cause hardship when paired off with steady men. If a 'butty' cannot be found for a miner, he must return home or work at 'company work' at a considerable loss to himself." It is a pity that owing to an apparent difference in scale, the Gallagher law, the variant mining conditions and the remoteness of the fields, Illinois mining men will not try to find work in the anthracite region. If they did the overplus in the Middle Western fields would readily solve the problem for the hard-coal producer. That the Illinois labor is not thus available is the more regrettable because the incoming soldiers in the anthracite region are not proving willing to settle down to their old employment. Returned soldier boys are not taking their old positions at the mines. They are spending vacations of varied length and then departing for the city centers in search of work. Many men are seeking employment as "company men," but few contract miners can be secured.

In the Big Sandy region of eastern Kentucky, especially in Pike County, no little labor trouble has arisen. It is said that the operators of the region are discharging men for joining the United Mine Workers of America, the trouble seeming to center around Pikeville where Vice President Pettry of District No. 17 and a party of organizers of whom he was in charge have been arrested. According to President Keeney further attempts to organize the mines around Pikeville were abandoned pending a meeting of the International Board at Indianapolis on Jan. 6. At the present time 2250 mine workers in the Kentucky field have joined the organization.

So much for eastern Kentucky. The other end of the state has its troubles. In Hopkins County, still a non-union field, the operators have asked the mine workers to accept a reduction of 5 per cent. in their wages because work has been slack. It seems quite probable that the men will accede to the demand made on them, for in the week ending Dec. 21 the idleness from lack of orders reached 26.9 per cent. and from all causes 42.2 per cent.

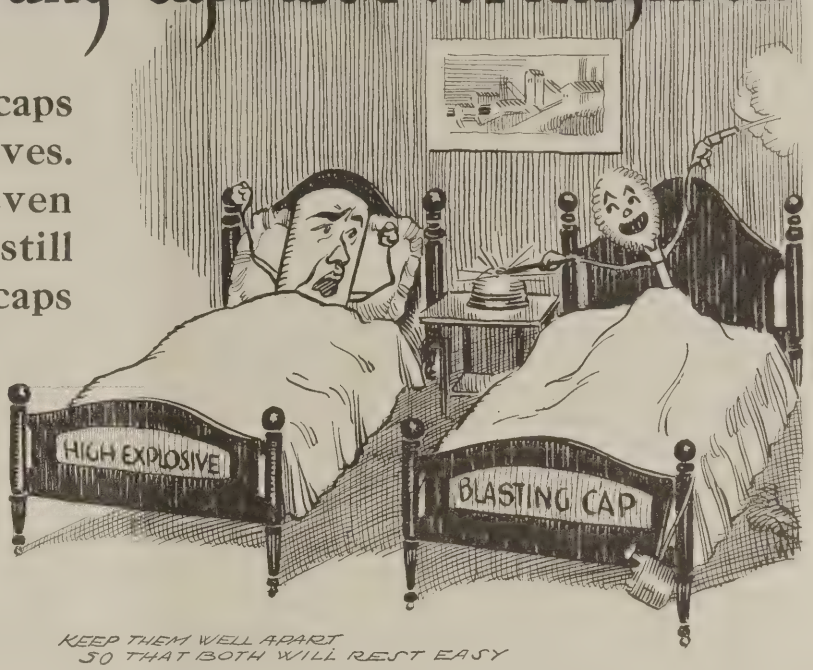
Anthracite Mine Workers' Insurgency

The old year at its end saw insurgency at its height in the first district of the anthracite region. On Dec. 28 an insurgent meeting was held by 125 delegates which by resolution instructed a committee to bring John Lewis and William Green, international vice-president and secretary respectively, before a convention of mine workers to explain the provisions of the recent wage agreement. Both the officers of the union have sent word that they will appear. President Frank J. Hayes, the international president, will not be able to attend.

The consent of Lewis and Green is tantamount to a recognition of the insurgent convention which is to be called despite the protests of the tridistrict board which is in charge of the labor destinies of the anthracite region. For two years there has been a growing disposition to contest the judgment of the ruling powers. A rival organization has even been built up. Now at last insurgency within has become so strong that insurrection is recognized. The insurgent does not have to leave the union. He now continues a member and modifies the administration of the union even if he does not actually regulate it.

Bolshevism in Illinois Mines

Illinois miners are becoming increasingly restive under the slow work which has prevailed since the armistice was signed. This feeling took form as a demand on the Government that it assume the ownership of the mines, the resolution being passed at a crowded mass meeting held at the Lyric Theater, Belleville, Ill., Sunday, Dec. 29. The meeting was called to discuss the present lack of employment and to decide upon a remedy.



After addresses by Duncan McDonald, former secretary-treasurer of the Illinois United Mine Workers, now secretary-treasurer of the National Coöperative Association; Andrew Wilson, of the Alliance of Labor and Democracy; President Daniels, of the Belleville sub-district; and Vice-President Carbine, of the Illinois State Federation of Labor, the following resolutions were adopted:

"Whereas, private ownership of coal mines creates acute competition in the market, and as, under the private ownership, mines are operated only for profit without regard to the interest of the miners, and whereas past experiences have proved that private ownership of mines and the operation of the same at such times as the private owners see fit has made the employment of mine workers insecure and worked a hardship on them and their families, and whereas there are hundreds of miners in the Belleville sub-district out of employment, and hundreds working less than half time due to private ownership and private management of mines, therefore be it resolved that the miners of Belleville earnestly and urgently call upon the House of Representatives and the Senate to enact a law providing for Government ownership of all mines in the country, and the democratic management of the mines by the miners employed therein."

St. Clair County, in which this meeting took place, is one of the biggest coal-producing counties in Illinois. When the resolutions were introduced Philip Veal objected to their adoption and urged that another resolution be drafted in favor of placing the mines under the control of a Workingmen's Council. He moved that three cheers be given "by the soviets of Belleville who are in sympathy with the soviets of Europe," but the three cheers were not given. They were headed off by calls for the adoption of the Government ownership resolutions, and the meeting proceeded to pass those resolutions as written.

Explosives and Blasting Caps are Poor Neighbors

DO not store blasting caps with high explosives. If they are kept even three feet apart there is still danger, because blasting caps go off easily; and when they explode they cause the high explosives to go off also, if they are at all near each other. Therefore, blasting caps and high explosives should be kept at least 10 feet apart.

KEEP THEM WELL APART SO THAT BOTH WILL REST EASY

What difference in effort does it make to you, when putting them both away, if you put them a few feet apart or put them both together? But what an awful difference it would mean should something accidentally set off your blasting caps when they are near your powder.

HE SHOOK THE FIRE OUT OF HIS PIPE AND STUCK IT IN WITH THE EXPLOSIVES.

Last year at a neighboring mine a man was carrying his blasting caps and two sticks of powder in his inside coat pocket. Without thinking, he shook the fire out of his pipe and stuck it in with the caps and explosives. The caps exploded and fired the explosives, and his entire side was blown off.

Think about this accident and don't carry explosives and caps together when you go into the mines. If you carry the caps, let your buddy carry the powder; or, if you must carry both yourself, carry caps and explosives in entirely separate places.

—Safety letter from a large company to its men.

Do Less and Have More

WORKINGMEN in England want the 44-hour week. If they want more leisure, the idea is not bad. If they think that in the shorter time they might be able to do just as much work, they would be advancing a proposition having some slight element of feasibility, especially in some lines of work. But strange to relate, instead of presenting either of these reasons, the British workmen say they want to reduce production.

They wish to reduce production, be it noted, with every mother's son of them complaining that they do not have enough, not of one thing but of everything. Where the things they produce go to, nobody knows. They produce too much and yet they have too little. Some one must dump part of the production into the Thames and the Mersey.

We all want more than we are getting. Write that in your political economy. If we all work more, we will make more and we will all have more; unless some one dumps the product in the Hudson and the Mississippi.

If there are at any time too many miners, leave the mines and go to producing something that it takes coal to produce, and which is in demand. Then you will, in doing that work, furnish a demand for coal that will revive the coal industry. If every one produces less, they will have to get along with less; for what is made is what we have, and what we don't make we don't have. "Do less and have more" is a fallacy.

Only for short periods, when people wilfully refrain from purchasing, are there too many artisans. Immediately thereafter there comes a glut of business; for a large part of what we have done without must eventually be bought, and what was left unbought and undone must largely be bought and done in the years that follow.

Perhaps in time of light demand it might be well to do less. We usually do; we work fewer days in the week or shorter time. But when demand is brisk we still keep up the practice of short-time work and try to take almost as many holidays as we did in the slack season. The result is that we buy less than we need in the slack periods and cannot get what we want and can buy in busy periods. Production is always a little behind the needed level.

A country like Great Britain, with its female percentage increased and its male percentage decreased, is not in prime condition for a shorter day. A country with a lot of cripples is not ready for experiments in the efficiency of shorter working hours. A country that is converting its plants from war work to peace work will not be helped by laboring less industriously.

Every nation has, in certain parts of its career, decried and lamented over-production. Yet year by year the amount of almost everything produced has increased per capita. We want more. Let us work to get it. Goods are not produced by Act of Parliament, but by toil. Still, if goods were producible by the fiat of the Labor Party in the palace of Westminster, the workingmen would not want them because they say: "Away with commodities. They smother us. We are surfeited with them. Do less that we may escape them. The more goods there are the worse our condition is." All of which is nonsense, for the progress of the working classes goes hand in hand with increased production.

Under-consumption and Over-production

SHORT hours and more frequent holidays are a good corrective of over-production whenever over-production occurs. It is a universal practice at the mines. Both operators and miners concur in it. Men are not discharged when business is slow. The same number of men are employed, all are given an equal turn, but the mine is shut down when the coal needed has been loaded onto the cars.

Unfortunately the short working days, which become frequent during these periods of over-production or under-consumption, tend to become the recognized hours for working; and holidays kept one year are likely to be regarded as necessary in the year following. In fact the tendency is to put the shortened hours and shortened time generally into contracts and thus make a binding law out of a mere practice, the provision necessary to meet a temporary condition thus being made obligatory when the condition no longer obtains. The human machine is thus hampered and choked down so that, when business improves and opportunity for steady work presents itself, full days and full weeks of days will not be worked.

An automobile driving through the country is held up at railroad crossings and road crossings. When it reaches the crowded city its progress is stayed at almost every street intersection. How does the chauffeur of the car react to these annoyances? Does he demand a slower car because it is evident he cannot travel steadily at the full speed of his automobile? Not at all. He looks for one that will make the requisite speed between stops and that picks up speed readily. He wants a faster, more responsive machine and not a slower one.

The labor machine is not much different. It is frequently stopped on the road or caused to run slow. It needs all the more to be speeded up between such occasions, for the more delays the more necessity for speed

The workingman faced by occasional short-time operation should prepare himself to do his utmost when occasion comes. He needs to keep in mind that when slack times end, and times are booming, he should be ready by greater diligence to make up for the time lost. Instead we find a disposition to meet the shortage of opportunity to work by the enacting of crippling restrictions which prevent a large production from being attained when the consumption is large and production cannot possibly supply it without maximum endeavor.

Halts in our progress and signs causing us to slow up, we must expect. Hills there will be that we cannot

take "on high." Curves there will be that we cannot negotiate at full speed. Consequently let us provide a machine, which, run on the level, can bowl along at a lively gait. Rarely is there an economic situation at any time or in any industry such as would assure absolutely steady work. The anthracite industry is now almost the solitary exception, and surely no one would suggest a reduction in output in that industry.

Perhaps the Government may eventually with success provide everyone with work when work is scarce. The suggestion has been made that the Government add this duty to its many other functions. The idea seems good, but having spent a billion or so on roads or schools when times are bad and taxes hard to pay, it will seem good to do the same when times are good and men are scarce, because taxes will be easily collectible. Governments are like the men they represent. They tend to do under one set of circumstances what they learned to do under the necessities of entirely different conditions.

The human mind individually and collectively takes on a permanent set, and the cure for adversity is taken long after the need for it has gone. The drug does its curative work, but the man who has been cured by it becomes an "addict." It would be a bad plan for a man who took cocaine and knew that it sapped his strength to pledge himself to take it indefinitely. It is bad for a union when it knows that shorter hours will hamper production to take on itself to advocate shorter hours indefinitely regardless of the demand of the public for the product of its members.

When the number of hours the members of a union are allowed to work is reduced, then in times of prosperity it is necessary to hire more men. The operator is obliged to go far and wide to secure them. He loads up the industry with labor, and at the next slack time it seems necessary to the miner to reduce the working hours again. As a result hours get indefinitely short, the cost of coal rises, and the consumer, who in the large is only another workingman, suffers. The condition of the miner is not improved. His work is not rendered steadier by the restriction in hours, and never will be. Restrictions in the number of men introduced into the industry is the only real cure, and that violates every law of industrial propriety. Industrial freedom requires that we shall be allowed to work at any job for which we have an ability, provided there is work to do in that line.

We Want To Get Too Much Out of the War

WE DID NOT enter the war for gain. We did not seek an acre of ground nor did we look for any little thing like a trade concession. It cost us a large loss in money and a far greater loss in lives. Nothing mercenary sullied the help we gave the allies during the war struggle; nevertheless, we are seemingly seeking in peace to gain a little too much out of the war, for when we desire things which are incompatible, we cannot get them, try as we may.

Before the war we were a debtor nation. We are so no longer; the debtor nations are now in Europe. Before the war we had no merchant marine; we are getting a marine service which may eventually outstrip that of Great Britain. Before 1914 Europe went her way without much thought of America; our well-to-do people went to visit Europe, but Europe, quietly self-satisfied, rarely returned the visit. It is likely that Europeans from now on will regard a visit to the United States as we have regarded a visit to France or Great Britain, as part of a liberal education. These are great gains, but they have their disadvantages.

When the war commenced in Europe that continent partly balanced her bills for what she bought from us (1) by the interest on our debt to her, (2) by the work of her merchant marine for us, (3) by the money expended by visitors to the great European resorts, (4) by the savings of the immigrants in America, sent home by various agents or taken home by the returning immigrant.

With these many ways of paying its bills, Europe was able to accept much merchandise from us and pay for it without sending us goods in return, goods which, to be frank, we did not want and which we tried to keep out entirely by tariffs. The payment by the work of the merchant marine, after once our merchant marine died a natural death from competition and the Civil War, did not introduce any difficulties in our national life. It did not paralyze any of our industries, for we owned no overseas transportation service of any considerable magnitude. We irked under the conditions, first because we had memories of the wonderful merchant marine of earlier days, second because we thought the greatest of nations should have a large mercantile marine, and thirdly, because we believed, probably erroneously, that the European shipowner discriminated in favor of European goods.

But after all, most of us would rather buy transportation of Europe than iron and steel and other products such as are made in quantities in our own factories. And yet it is not material whether we would or would not rather buy transportation than steel; the fact remains that if we will not buy transportation we must buy something else. Bills must be paid. Europe owes us more than we ever owed her, and the interest charge is large and must be paid regularly. If she buys transportation of us instead of selling it, we must accept pay in merchandise; and if Europe repays our visits and spends money here, we shall have to settle for what Europe expends here by the buying of more goods.

There is a new order of things. We play now the rôle of the rich man for whom others labor. Most people like that part in the world's comedy. But nations have a queer way. They do not want others to work for them. The mark "Made in Germany" was gall and wormwood for the Britisher. He could not bear, even before the war, to think of a German splitting blocks of wood for him into match sticks or coating the tips with sulphur and phosphorus or fabricating matchboxes. Nor did he respond otherwise when he read "Made in Sweden." He resented it.

Almost as reasonably might the mine owner object if he saw a car of coal coming out of his mine marked "Mined by John Smith." Would he resent John Smith's mining a car of coal for him? If he did, how long would he be an operator? Is he to feed John Smith and his family? Is he to house him and clothe him without permitting him to mine him a car of coal, at least now and again? Is it not rather his arrogant way to want the said John Smith to mine two cars, so long as he, the operator, knows a way of disposing of the coal and has the money to pay for it?

DISCUSSION BY READERS

Accounting of Materials

Letter No. 3—The letter of A. T. Lament, dealing with the subject of accounting of materials in mining practice, *Coal Age*, Nov. 21, p. 956, proved very interesting to me, as I have tried for a long time to find a simple and yet foolproof system of keeping track of the labor and supplies of material sent into the mine. I have been particularly desirous of finding a method that would insure charges being placed to their proper accounts, and it is this feature of Mr. Lament's letter that is most helpful.

The strongest recommendation of any system is the fact that it has stood the test of actual use around a mine, and the statement of its author that the system he describes has been in practical use for several years makes it worthy of careful study. A half-baked system is worse than none at all. Recently, so many inferior systems have been advocated that it is a comfort to find a system that has stood the practical test.

In studying Mr. Lament's letter, however, I found, very much to my regret, that he did not enter into the cost of haulage in the mine, in detail. Mine haulage is a subject that is hazy, in the minds of most coal operators, in respect to itemizing the cost. They have found it exceedingly difficult to differentiate between these different items.

Items Frequently Charged to Wrong Accounts

I am glad to see that the subject of cost accounting in mine haulage is under discussion in *Coal Age* and hope it will evoke some interesting details regarding these costs. Frequently, car repairs are charged to some other account when they properly belong to haulage, and the same is true of locomotive repairs, track repairs, and similar items. At least, that is the way it appeals to me.

About the most difficult item to apportion, however, is the cost of power. This has been referred to in the excellent letter of J. Kenvin, Dec. 26, p. 1175. It is my belief that the cost of power consumed in gathering work should be separated from that required for haulage on the main roads, in order to make an intelligent showing that would assist in securing the greatest economy in these two branches of the work.

I have consulted some of the best authorities on the subject of mine haulage, without arriving at any satisfactory results. The general opinion is that conditions in mines vary so greatly, that it is impossible to devise a system that would be generally applicable for determining these costs.

Although I realize the complexity of this subject, it does not deter me from wishing to place the question squarely before the readers of *Coal Age*. I feel that some of our practical men, experienced in coal-mining practice, will be able to suggest ways out of these difficulties and simplify the seemingly complicated question of properly distributing mine-haulage costs. We may rightly expect that the average of these suggestions would put us all on the right track to secure greater economy in production. PROGRESSIVE.

———, W. Va.

Centrifugal Mine Pumps

Letter No. 1—Referring to the reply to the inquiry of "Superintendent," regarding the relative size of suction and discharge pipes and the corresponding openings in a centrifugal pump, which appeared in *Coal Age*, Dec. 5, p. 1049, permit me to say that my experience in installing centrifugal pumps for the pumping of gritty, acid mine water, in the Southern anthracite field and at other points, leads me to differ with the idea set forth that the column pipe into which a centrifugal pump discharges should have a larger diameter than that of the discharge portal or opening.

The use of a column pipe having a diameter larger than that called for by the opening flange in the pump casing may cause serious difficulty if there is an abrupt change from one size of pipe to another. Air would accumulate at this point and, slipping by the column of water, would allow the latter to fall and cause a shock to the impeller and possibly burst the column pipe or do other serious damage.

However, if the increase in size from the discharge opening in the pump casing to the larger size of the column pipe is obtained by introducing a section of pipe with a gradually increasing diameter, which would afford no opportunity for the lodgment of air, little difficulty will be experienced by the use of a larger pipe, either for the suction or for the column pipe than what is called for by the respective flanges.

It is my opinion, however, that no distinct advantage would be obtained by enlarging either the suction or the column pipe. The statement that a 9-in. discharge opening would call for a 16-in. column pipe does not agree with my experience or with manufacturer's ratings. The suction and discharge opening flanges are correct for the suction and column pipes, respectively.

Pumps Are Designed for a Given Head

Replying to the second question asked by the correspondent, regarding the effect of a greater or lesser head than that for which a centrifugal pump is designed, let me say that the effect is to decrease the efficiency of the pump, in either case. Operating a centrifugal pump under a *lesser* head than that for which it is designed increases both the discharge of the pump and the horsepower required for its operation. The contrary is the case when the pump is operated under a head *greater* than that for which it is designed. The discharge will then be decreased and a less horsepower will be consumed in driving the pump. But, in either case, the efficiency of the pump is decreased.

To illustrate this point, let me assume a five-stage centrifugal pump running at a speed of 1170 r.p.m. and discharging 1000 gal. per min., under a head of 550 ft. In this case, 200 hp. is delivered at the coupling to the motor and the pump is yielding an efficiency of 72 per cent. This pump has a 6-in. discharge and an 8-in. suction opening in the casing and is provided with a 6-in. column pipe and an 8-in. suction pipe. The maximum head at which a centrifugal pump will operate is dependent upon the peripheral velocity of its impeller.

The pump just mentioned, running at the same speed, will discharge 400 gal. per min. against a head of 665 ft., consuming 130 hp. at the coupling to the motor and yielding an efficiency of 52 per cent. Again, at the same speed, this pump will discharge 1400 gal. per min. against a head of 350 ft., consuming 210 hp. and yielding an efficiency of 55 per cent.

Operated against no head, the same pump will discharge 1540 gal. per min. and consume 230 hp. while so doing, showing no efficiency. Under a head 600 ft., the pump consuming 14 hp., the efficiency is zero and the quantity zero. It is apparent that this pump will operate successfully anywhere between the limits mentioned, but will give the greatest efficiency under the conditions for which it was designed.

Effect of Curving Impeller Blades Forward

The remarks just made refer to a centrifugal pump designed with the blades of the impeller curved backward from radial, in the direction of rotation. This is the least efficient way to design a pump, from a power-consumed point of view; but, everything considered, it is the most satisfactory operating unit. An impeller with blades radial or curved forward will cause a serious overload when operating against a head less than that for which the pump is designed.

Regarding the length of suction, as stated in the reply to this inquiry, a long suction is always a distinct disadvantage. A great length of suction might cause the failure of the pump, owing to the inertia of the mass of water in the suction pipe. It may happen that the pump will run away from the suction; or, in other words, pump the water from the casing quicker than the partial vacuum, owing to the drag in the suction pipe, can replenish the space vacated by the water pumped.

When starting a centrifugal pump having a long suction, a very perceptible period of time is required to accelerate the mass of water in the suction pipe and give it a velocity that will supply the pump or equal its discharge. In that case, a void space is formed between the water in the suction pipe and the water in the pump. The pump will then suck air, which reduces the vacuum, and the operation of starting must be repeated. For this reason, the discharge valve in the column pipe should always be closed when starting a centrifugal pump.

Wm H. Grady,
Pottsville, Penn. Consulting Engineer.

[The exception taken by this correspondent to the statement made in the reply to the inquiry to which reference has been made is not supported by the statements and practice of the leading manufacturers of centrifugal pumps. While it goes without saying that an expanding section of pipe is required to connect the discharge opening of a centrifugal pump with the larger size of the column pipe, it is an unquestioned fact in all pumping practice that there is a large saving in power when the velocity in the column pipe is moderately reduced, say to 6 or 8 ft. per sec.

On the other hand, the high velocity of discharge of water from the pump casing demanded by the high speed of the impeller of a centrifugal pump calls for a considerable reduction of this velocity after passing the discharge portal and before entering the column pipe leading to the surface. This reduction of velocity is, of course, to be made gradually by an expanding section of pipe, as explained.

The following are brief quotations from the publications of three of the leading manufacturers of centrifugal pumps:

It is advisable to make suction and discharge piping one or two sizes larger and connect same to the pump, by means of an increaser. There is a decided advantage in doing this, for it effects a saving in power at the mines or a gain in pressure and an increased suction lift if necessary.

Another manufacturer states as follows:

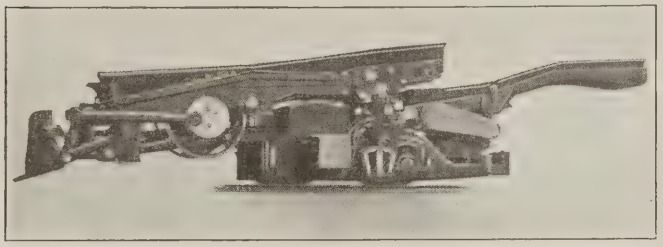
The suction and discharge pipes should be selected several sizes larger than the suction and discharge openings of the pump. The suction line should be carefully laid so as to avoid the possibility of the formation of air pockets in the same.

Still another manufacturer states the following:

As a rule, a velocity of 6 to 8 ft. per sec. should not be exceeded in piping, as a higher velocity is apt to result in excessive friction loss. It is also true that seldom, if ever, should the piping be installed of the same size as that of the outlet or inlet of the pump. Centrifugal pumps must necessarily have a high velocity through the casing, in order to obtain a high efficiency; and, thus, the size of the openings of a properly designed centrifugal pump is no gage whatever of the proper size of the piping to be attached to them. The only correct method of determining the pipe size is one which includes a careful analysis of the velocity of the water through the piping, length and character of the piping, number of fittings, bends, etc.

Our thanks are due this correspondent, however, for his remarks regarding the effect of a greater or lesser head than that for which a centrifugal pump is designed. As he has stated, there is always a loss of efficiency when a centrifugal pump is operated under a lesser or a greater head than that for which it is designed. In designing a pump to give a desired discharge, the greatest efficiency can only be secured when the discharge is proportionate to the square root of the head. In other words, in respect to securing the highest efficiency, this type of pump is subject to limitations regarding the ratio of the discharge to the square root of the discharge head.—Editor.]

Portable Coal Loaders



Letter No. 2—Speaking of portable coal loaders, to which recent references have been made in *Coal Age*, and referring particularly to the inquiry of "Operator," Nov. 21, p. 961, kindly permit me to draw attention to still another type of this class of machinery worthy of mention. I refer to the Halby shoveling machine, designed for underground shoveling and loading, Lake Shore Engine Works, Marquette, Mich.

Having seen this machine in operation at Braznell, Penn., and at North Fork, W. Va., and knowing that it is doing good work and giving satisfaction in each case, I thought that many of the readers of *Coal Age* would be glad to know a few facts regarding the value of this class of equipment in coal mining.

The Halby machine is built in three types, varying from 7 to 10 tons in weight. The machine is built to operate on any track gage and uses either compressed

air or electricity, as desired, although electrical operation of the machine is recommended. The electrical machine is ordinarily equipped with a 25-hp. motor. The trucks are mounted on Hyatt roller bearings and a worm drive is provided, by means of which the machine is self-propelled. All parts of the machine have been designed to withstand severe service.

In the accompanying figure is shown the machine known as the "T700" machine, which has an overall length of 23 ft. 4 in., an overall width of 4 ft. 8½ in. and an overall height of 4 ft. 6 in., being designed especially for operating in 5-ft. coal. Another model, the "T600," has an overall length of 23 ft. 2 in., a width of 5 ft. 2½ in. and an overall height of 5 ft. 10½ in. The widths given do not include the operator's

THE "HALBY" SHOVELING AND LOADING MACHINE

platform, which extends 10½ in. on the right or left side of the machine, as desired.

The power and truck sections, which are separate units in the T700 model, are combined in the T600 model. Also, the rear conveyor, in the former machine, is arranged to discharge its material, either into a car standing on the same track or on a track parallel with that on which the machine is operated. The T600 model can discharge its material only into a car standing on the same track, behind the machine.

There is no limit to the size of the coal handled by these machines, except the limitation imposed by the headroom in the mine where the machine is operated, since the material must pass over the top of the conveyor, under the roof. Lumps weighing 1500 lb. are readily lifted in the dipper or scoop of the machine, transferred to the rear conveyor and loaded into the car waiting to receive the material. These facts should be of interest to all coal operators. OBSERVER.

Pittsburgh, Penn.

Specific Gravity Determination of Coal

Letter No. 1—Kindly permit me to add a word to my previous article, which appeared in *Coal Age*, Dec. 12, p. 1078, on the determination of the specific gravity of coal by a rapid method that gave practical results. While the process then described is correct, I have since found that the following slight modification is of advantage when but a few samples of the coal are to be handled in the determination:

After the 100 c.c. of water has been added from the pipette and the flask has been shaken, more water is added, as previously described, at the bottom of the second column, page 1078. But, before the flask is filled to the mark, 5 c.c. of oil is added from a small pipette. This 5 c.c. of oil must be accurately measured and is, therefore, best added from a 5-c.c. "delivery pipette," or, if desired, a "capacity pipette" may be used. In that case, however, the same pipette should be used in calibrating the flask. After adding the oil, fill the flask to the mark with water, and calculate the results as described before. A. G. B.

Pottsville, Penn.

Letter No. 2—In the article by A. G. Blakeley, published in *Coal Age*, Dec. 12, p. 1078, attention is directed to the possibility of quickly estimating the approximate percentage of ash, in commercial samples of anthracite coal, by determining the specific gravity of an average sample.

Mr. Blakeley describes simple and excellent methods for such determinations, and gives interesting data covering 119 samples of coal, all of which were taken from one colliery. These data are quoted in illustration of the relation of ash to specific gravity, and from the figures given the specific gravity of "ash-free coal" can be calculated.

For example, using the figures given by Mr. Blakeley, in different combinations, we may calculate the specific gravity of ash-free coal as follows:

	Specific Gravity	Ash Per Cent.	Sp. Gr. "Ash-free" Coa (Calculated)
Chestnut	1.61	12.89	1.4748
Rice	1.75	26.24	
Buckwheat	1.67	18.27	1.4726
"Boiler fuel"	1.86	35.86	
Chestnut	1.61	12.89	1.4700
"Boiler fuel"	1.86	35.86	
Average			1.4725

The remarkably close agreement shown by these figures prove the determinations quoted by Mr. Blakeley were made with great care and accuracy. The same figures, if similarly used to calculate the specific gravity of the ash content, show that the average specific gravity of the ash is surprisingly high, being about 2.55 to 2.56. Possibly the presence of an unusually large quantity of pyrite in this particular coal may account for the apparently high gravity of the ash.

Diagrams of Anthracite and Bituminous Coal

An article in the February, 1918, Bulletin of the American Institute of Mining Engineers and a similar article published in the August, 1918, Journal of the Engineers' Club of Philadelphia, contains a diagram that I prepared to illustrate the relation of the specific gravity of bituminous coals to their percentages of ash and sulphur (pyrite). Had the data been available at that time, I should have prepared a similar diagram to show a like relation as existing between the specific gravity and ash of anthracite coals. Mr. Blakeley's paper furnishes the data from which such a diagram can readily be constructed.

It would be seen, at once, that these diagrams are remarkably similar. The bituminous-coal diagram shows an increase of 1.46 — 1.25 = say 21 points, in specific gravity, corresponding to an increase of 20 per cent. in ash content; or 21 ÷ 20 = 1.05, for each per cent. increase in ash.

Similarly, the figures from which an anthracite diagram can be drawn show, in one instance, an increase of 1.75 — 1.4725 = 27.75 points, in specific gravity, as corresponding to an increase of 26.24 per cent. of ash; or 27.75 ÷ 26.24 = 1.057, for each per cent.

In another instance, the anthracite figures show an increase of 1.86 — 1.4725 = say 38.75 points, in specific gravity, as corresponding to 35.86 per cent. increase in ash; or 38.75 ÷ 35.86 = 1.081, for each per cent. increase in ash content.

It will, of course, be understood that an anthracite diagram prepared from this data will not be applicable to coals of lighter specific gravity, such as those of the Scranton-Wilkes-Barre district in which the specific gravity of ash-free coal is probably about 1.38; but the *ratio of increase* in specific gravity, for each increment in the percentage of ash, remains approximately the same as that given above; namely, from about 1.057 to 1.081, for each increase of 1 per cent. in the ash. As a ready means for quickly and approximately calculating the ash from the specific gravity, or *vice versa*, Mr. Blakeley has used the factor 1, which is sufficiently accurate for ordinary purposes.

Data Must Correspond to the Quality of Coal

Objection may perhaps be made to this method of determining the specific gravity of ash-free coal, on the ground that the figures given by Mr. Blakeley represent the specific gravity of a mixture of coal and slate, rock, bony coal and other impurities existing in anthracite, as prepared for shipment, or for local use.

By the methods in use, it is impossible to remove all of the slate and rock from coal shipments. It would be contrary, moreover, with proper regard for the conservation of our fuel supplies, to remove all of the bony coal, because most of this grade has a relatively high thermal value. It is entirely possible, however, that the impurities constituting the ash of the coal may not be of the same specific gravity as that of the slate, which is mechanically mixed with the coal. When that is the case, of course, the specific gravity of the ash-free coal is not 1.4725, and other data must be used.

While it will certainly be understood that there can be no such thing in nature as "ash-free" coal, yet the specific gravity of such basic coal must be the imaginary starting point of diagrammatic curves, useful both for laboratory and commercial purposes. Data bearing on such assumed basic coal is therefore useful, important and valuable. Unfortunately there are few published data available for reference. Richard's treatise on Ore Dressing gives the specific gravity of anthracite (the ash not stated), as varying from 1.32 to 1.70, and other reference books are equally vague.

To determine accurately the specific gravity of so-called "ash-free" coal in each of the anthracite districts, it would seem necessary to have a series of determinations of the average *specific gravity and ash percentage* of: (1) High-grade (very low in ash) hand-picked samples; and (2) low-grade (high in ash) hand-picked samples. Such samples should include no slate or rock, or coal that could be classed as bony coal. From these two sets of determinations, it would then be possible to calculate the specific gravity of the impurities of the coal that constitute the ash and the specific gravity of a basic "ash-free" coal for the district or coal bed from which these samples were secured.

The publication, by Mr. Blakeley and other chemists engaged in anthracite coal work, of data of this nature would be a valuable contribution to our knowledge, in a field that seems to have been almost entirely neglected. This subject is of further interest in its relation to the question, often asked but never conclusively answered, "What is coal?" Is it a *mechanical mixture* of carbon, clay, silica, etc., containing condensed or entrained gaseous, hydrocarbon compounds; or are some or all of the hydrocarbon and other gaseous elements chemically combined with the carbon of the coal; or are some or all of the constituents of the ash chemically combined with the carbon or the hydrocarbon constituents?

In connection with the development of the coal-washing method invented by Thomas M. Chance, which effects the *complete* removal of slate and rock, by the flotation of the coal and bony coal, a series of determinations of the specific gravity of commercial grades of anthracite have been made. Many of these determinations were checked by using chloride-of-zinc solutions, the specific gravity of which was accurately fixed. Most of these determinations were made on coals coming from the southern and middle anthracite fields.

As the efficiency of the Chance method depends entirely upon differences in the specific gravities of coal and bony coal, on the one hand, and slate and rock, on the other, the difference in the specific gravities of the coals from the southern and the northern districts was carefully noted, in order to adjust the specific gravity of the fluid mass required to make a perfect separation. The results we have obtained are generally in substantial agreement with the much larger number of determinations given by Mr. Blakeley in his article; but, as already stated, these results cannot be applied to the lighter coals of the northern districts.

Philadelphia, Penn. H. M. Chance.

The following is the method of calculating the specific gravity of ash-free coal and of the ash, respectively, as explained by Mr. Chance, at our request:

	Specific Gravity	Ash Per cent.	Ash-free Coal, Per cent.
Chestnut	1.61	12.89	100 — 12.89 = 87.11
Rice	1.75	26.24	100 — 26.24 = 73.76

Calling the specific gravity of ash-free coal x, and that of the ash a, considering a unit weight of each of these grades of coal, we write

$$0.8711x + 0.1289a = 1.61 \quad (1)$$
$$0.7376x + 0.2624a = 1.75 \quad (2)$$

Combining these two equations to eliminate a, and finding the value of x, we have

$$x = 1.4748$$

Similar calculations for buckwheat and boiler fuel give $x = 1.4726$; and for chestnut and boiler fuel, $x = 1.4700$. The average of the values gives for the average specific gravity of ash-free coal, for this quality of anthracite, as $x = 1.4725$.

Again, solving equations (1) and (2), with respect to a gives for the average specific gravity of the ash, for this quality of anthracite, $a = 2.55$.

Reducing Ventilation at Firing Time

Letter No. 2—The question of reducing the circulation in a mine, at the time of firing, has again been brought to the attention of readers, by the letter of John Verner, *Coal Age*, Nov. 28, p. 1000, in which he urges once more the importance of the air factor in producing explosive conditions in mine workings.

It would seem in this, as in all other practices in coal mining, both operators and miners are prone to stick to the old methods with which they have been long acquainted. It will take some time to convince many mining men that their fans should be shut down, or at least slowed down, before shots are fired in the mine. Others, who have been forced to adopt this practice, will be just as hard to induce to go back to the old system.

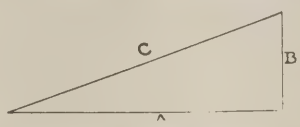
In some mining districts, the practice of reducing the circulation of air in a mine when firing has been adopted and followed for a considerable time. Other districts have made no change in the quantity of air in circulation, while in still other districts the practice is to increase the circulation by speeding up the fan when the time for firing shots has arrived. It would seem, therefore, that mining men do not have a common understanding of what is the safest method to pursue.

There is a mine, in Indiana, that has had the practice of shutting off the circulation when firing and, in that mine, a number of accidents have occurred from blown-out shots. In other mines in the same field, the ventilation has been unchanged at firing time, and it is worthy of note that fewer accidents have happened in those mines than in the one just mentioned. This is not necessarily, of course, to be attributed to the practice of reducing the ventilation in the mine first named. The frequency of accidents in that mine may have been the result of improper practices in drilling and blasting the coal.

Bad Practices in Blasting Coal

At some mines in southern Illinois, it was no uncommon thing, a few years ago, for explosions to occur as often as once or twice a week. Some of these were very severe while others were not so bad. These explosions, however, were caused by the excessive use of powder in blasting, and locating the charge too far on the solid. It was nothing unusual there, at that time, for miners to drill their holes from 8 to 10 ft. in depth, which would invariably put the charge on the solid, where it would have no opportunity to perform its work, and the result would be a blown-out shot. One of these shots was reported as 12 ft. deep and measuring 6 ft. on the heel and 12 ft. on the point. But it was not fired, as it would undoubtedly have caused another explosion.

Mr. Verner's contention, I believe, is that the circulation in a mine should only be reduced where there is no danger from the accumulation of gas. It would seem advisable that the circulation should be reduced in a dusty mine, at firing time, in order to reduce the quantity of dust floating in the air. But, where a mine is generating gas in quantities that would produce a dangerous accumulation during the period of firing, unquestionably, the circulation should remain unchanged. Any interference with the ventilation, in such a mine, would be dangerous.



Although I have had no experience in gaseous mines, it is my belief that the question of reducing the ventilation at firing time is limited to mines not producing gas in dangerous quantity. As this question is an important one, I hope to see it discussed from different viewpoints, by men who have had experience both in gaseous and dusty mines and in mines generating no gas or dust.

Cleaton, Ky. Ostel Bullock.

Estimating Percentage of Grade

Letter No. 2—Referring to the letter of Joseph R. Thomas, *Coal Age*, Nov. 21, p. 959, permit me to say that the method he mentions of estimating the percentage of grade based on horizontal measurement is simple enough, but does not apply to cases where the percentage of grade is referred to pitch measurement.

Kindly permit me to give two methods that I have used in calculating the percentage of grade referred to pitch measurement. The first is as follows: In the triangle *ABC*, *A* is the horizontal distance corresponding to the pitch measurement *C*, and *B* is the rise of the incline for that distance. It is evident that, since this is a right triangle, the hypotenuse *C*, representing the pitch distance, is equal to the square root of the sum of the squares of the horizontal distance *A* and the rise or difference in elevation *B*, as expressed by the formula

THE INCLINED PLANE

$$C = \sqrt{A^2 + B^2} \qquad (1)$$

But the percentage of grade when based on pitch distance is equal to the difference of elevation between two stations divided by the distance measured on the pitch between those stations. Therefore, calling the percentage of grade x, this is expressed by the formula,

$$x = \frac{B}{\sqrt{A^2 + B^2}} \qquad (2)$$

Following is the second method: Referring, again, to the triangle *ABC*, since the percentage of grade referred to pitch distance is equal to the rise *B* divided by the pitch distance *C*, it is expressed by the sine of the pitch angle or the angle of inclination of the plane, which is the angle formed by the lines *A* and *C* in the figure. Therefore, knowing the difference in elevation between two stations and the horizontal distance between them, as given on the mine map, the first step is to find the pitch angle. The tangent of this angle is equal to the difference in elevation divided by the horizontal distance between the stations, measured on the map.

$$Tan\ a = \frac{B}{A} \qquad (3)$$

Reference is then made to a table of sines and tangents, in order to find the sine corresponding to this calculated tangent.

For sake of illustration, assume the horizontal distance between two stations, as taken from the mine map, is $A = 400$ ft., and the difference in elevation, 30 ft. Then, estimating the percentage of grade by the first method given, substituting these values in Equation 2, we have

$$x = \frac{30}{\sqrt{400^2 + 30^2}} = \frac{30}{401} = 0.074, \text{ or } 7.4 \textit{ per cent.}$$

Again, making the same calculation by the second method given, substituting the same values in Formula 3, we have

$$Tan\ a = \frac{30}{400} = 0.075$$

The angle corresponding to this tangent, as taken from the tables, is 4° 17′, and the corresponding sine of this angle is practically 0.074, which makes this grade 7.4 per cent., as before.

Let me suggest, here, that it is not necessary, as Mr. Thomas states, to calculate the pitch distance by dividing the distance on the map by the cosine of the angle of inclination. Although, in the case I have assumed, there is slight difference between the tangent and the sine of the pitch angle, this difference is greater as the angle of inclination is increased.

West Pittston, Penn. Richard Bowen.

INQUIRIES OF GENERAL INTEREST

Smoky Coals

Please say why soft or bituminous coal makes a much darker smoke when burning than anthracite.

Wilkes-Barre, Penn. STOKER.

Bituminous coal contains less fixed carbon and much more volatile matter, consisting largely of hydrocarbons and tarry substances that are not consumed in the furnace and escape with the gases produced by the combustion of the coal. It is these solid particles of unburned carbon that form the darker smoke of bituminous coal.

Safeguards in Trolley Haulage

Kindly explain the simplest and best method of protecting the trolley wire in mine haulage, so as to avoid accidents from men and animals coming in contact with the wire and receiving a shock that might prove fatal. We are using a 250-volt, direct-current circuit for haulage in our mine.

Also, explain how the trolley wire should be arranged so as to avoid its crossing room necks, where trolley locomotives are used on gathering hauls.

Bicknell, Ind. MOTORMAN.

Probably the simplest method that can be employed to safeguard a trolley wire, in mine entries, is to protect it at all points where men and animals must pass under the wire, by suspending light boards on each side of and parallel to the wire, at such points. The boards should be 1 x 6 in. and supported by strong hangers of strap iron secured to the roof by expansion bolts driven into holes drilled for that purpose.

The boards should extend an inch or two below the trolley wire and be spaced about six inches apart. When properly arranged they offer no obstruction to the passage of the trolley, but furnish ample protection against accidental contact with the wire owing to neglect or careless indifference to the danger. Sometimes the boards are made to swing, by hanging them on eyebolts, but that is not essential.

Trolley wires should be hung on substantial insulated supports, and follow one side of the track only. The wire should hang about 6 in. outside of the rail, on the side of the track opposite to that where clearance is provided for the necessary passage of men in the performance of their duties in the mine.

The use of old rubber hose, where this is available, has been suggested as being an excellent substitute for boards, for the protection of trolley wires at crossings where men and animals must pass. A sufficient length is first cut from the old hose and then split open and hung in place of the boards. The rubber being pliable and a good insulator is forced up against the trolley wire by anything striking it and insures perfect insulation from the current.

In electric haulage, nothing is of greater importance than that the installation be made by a competent mine electrician—that is to say, an electrician who has had experience in coal-mining practice and understands the conditions that surround the work in the mine. Only such an one is competent to decide what safeguards are necessary for the protection of the workers and to provide practical appliances.

In answer to the second question asked, let it be said that where trolley wires are hung on producing entries the wire should be carried on the opposite side of the entry from that on which the rooms are turned, except where it is impracticable to make such arrangement. Only in exceptional cases should a trolley wire be carried across the mouth of a room, and then it must be properly guarded.

Locomotives equipped with two trolley poles have been used in some mines, which make it possible to take power from either side of the entry. In that case, the trolley wire could be transferred from one side of the entry to the other with slight inconvenience. The use of such a 2-pole locomotive would obviate the necessity of carrying the trolley wire across the mouths of the rooms.

Coal Resources of Germany

Will *Coal Age*, or some of its readers, kindly inform us what are the coal resources of Germany? Have any large additional coal reserves been discovered recently; and if so, where are they located? At the present time, this question should be of particular interest to all interested in the future development of the coal trade throughout the world. LIGNITE.

———, Mont.

The question asked by this correspondent has, indeed, an interesting bearing on coal-trade development following the great war. Some of the most valuable of the coal deposits of Germany are located in the Alsace-Lorraine territory, which the Germans took from the French in 1870 and which now falls, again, into the possession of France, as a result of the recent allied victory.

Little information is available in regard to any recent discoveries of coal deposits in Germany. The latest publication bearing on the coal resources of Germany is that given in the report of the Executive Committee of the Twelfth International Congress, Vol. 3, entitled "The Coal Resources of the World." This report, which is wholly in German, can be found in the leading libraries. It was issued in 1913, the year previous to the outbreak of the war.

Probably some of the readers of *Coal Age* can furnish facts or offer information that will be of interest in reference to the coal deposits of the Central Empires, and their present and prospective development.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—In a mine giving off 2500 cu.ft. of marsh gas per minute, the volume of air entering the intake opening is 4,000,000 cu.ft. per hour. What is the percentage of gas in the return current? Would you consider this percentage of gas dangerous?

Ans.—The circulation, in this mine, is 4,000,000 ÷ 60 = 66,666 cu.ft. per minute. The total volume of air and gas passing in the return airway is, therefore, 66,666 + 2500 = 69,166 cu.ft. per minute, and the percentage of gas in this return current is (2500 ÷ 69,166)100 = 3.6 per cent.

This percentage of gas is far too dangerous under any mining conditions, and immediate steps should be taken to withdraw the men and improve the circulation in the mine.

Ques.—When air splits are necessary in mines, how would you determine their limit of usefulness?

Ans.—The practical limit to splitting air currents in mines is determined by the resulting velocity of the air passing the working faces. Under ordinary conditions, this velocity should not fall below 3 or 4 ft. a second. If the mine is generating gas, the velocity of the air current must be sufficient for the removal of the gas and prevent its accumulation in pockets in the roof or in other void places. The necessary velocity of air in mine workings depends much on the pitch or dip of the seam.

Ques.—What is the breaking strain of a good steel hoisting rope 1½ in. in diameter?

Ans.—The breaking strain of a 6-strand, 19-wire, steel hoisting rope is found by multiplying the square of the diameter in inches by a constant depending upon the quality of the steel. This constant for ordinary cast steel is 34; for crucible cast steel, 39; and for plow steel, 44. These constants represent the breaking strain of a 1-in. rope of each respective quality of steel. Therefore, the breaking strain of a 1½-in. crucible cast-steel rope, having 6 strands of 19 wires each, is

$$S = 39(1\tfrac{1}{2})^2 = 87\tfrac{3}{4} \text{ short tons.}$$

Ques.—Why is afterdamp a variable mixture?

Ans.—The composition of the afterdamp of an explosion of gas in a mine will vary with the percentage and the kind of gases in the firedamp mixture before the explosion. The character of the afterdamp will also depend on whether or not dust took part in the explosion and what amount of dust was present, and the quantity of air in circulation. These are the principal conditions affecting the completeness of the explosion and the character of the gases forming the afterdamp.

Ques.—A rectangular collar 10 in. deep supports 3000 lb.; what will it support if its depth is increased to 12 inches?

Ans.—Assuming this collar is uniformly loaded and supported at both ends, the load it will support varies as the square of the depth of the collar or beam, the width of the beam remaining unchanged. Calling the maximum safe load, for a depth of 12 in., x, we have $x : 3000$; $12^2 : 10^2$; and, $x = (3000 \times 144) \div 100 = 4320$ pounds.

Ques.—If the quantity of air in the downcast weighs 1800 lb., the depth of the shaft being 300 ft., and the difference of weight of air in the shaft is 250 lb., what will be the length of the motive column?

Ans.—In replying to this question, it must be assumed that the reference here is to two shafts of equal depth, sunk from a level surface. It is also assumed that the shafts are of the same size in cross-section, and that, while the weight of the volume of air in one shaft is 1800 lb., that of an equal volume of air in the other shaft is 250 lb. more or less than that amount. On this basis, it may be calculated that the weight of air in the first shaft is 1800 ÷ 300 = 6 lb. per foot of depth. Then, the difference in weight of air in the two shafts being 250 lb., the length of motive column, under the assumed conditions, is 250 ÷ 6 = 41⅔ feet.

In mine ventilation, the motive column producing a circulation of air is calculated by dividing the pressure producing the circulation, expressed in pounds per square foot, by the weight of a cubic foot of the air, which gives the corresponding motive column, expressed in feet.

Ques.—What would you consider was the cause of a flame traveling down a 100-ft. room and out on the entry, when a shot was fired at the face of said room, and what remedy would you apply to prevent danger?

Ans.—Such an occurrence points to the probable existence of an inflammable atmosphere in the room, caused by the presence of gas or dust or both. The gas- and dust-laden air, ignited by the flame of the shot, causes a local dust explosion at the face of the room, and the consequent projection of the flame from the mouth of the room onto the entry. The same result is also caused, at times, by the occurrence of a blown-cut or windy shot exploded at the face of a room. In the presence of gas or dust, such a shot will invariably produce a local explosion and a large volume of flame will be projected from the mouth of the room, unless the force of the explosion is exhausted before it reaches that point.

In order to prevent such occurrences, strict regulations must be made and enforced in regard to blasting the coal. All holes drilled must be properly mined or sidecut, and no holes permitted to be located or drilled to such a depth that the charge will be placed on the solid. Every hole should be inspected before it is charged, and the weight of the charge limited to a specified amount. The best plan to pursue is to employ shotfirers whose duty is to inspect, charge, and fire all holes that in their judgment are safe. Care must be taken that no shots are fired in the presence of gas, and all accumulations of dust at the face avoided.

COAL AND COKE NEWS

Harrisburg, Penn.

The fact that the Pennsylvania Railroad Co. is demanding and receiving from the mines on its lines east of Pittsburgh 1152 cars of coal a week, which is commandeered by the Pittsburgh fuel administration officials and turned over to it, is causing complaint from operators, byproduct concerns, mills and manufacturers. The coal commandeered by the railroad is of the metallurgical grade, used for coke, byproducts and manufacturing purposes generally. Little of this coal is of the steam variety, and the operators say that it should not be used for steam-making purposes by the railroad when it is so badly needed for metallurgical consumption.

The Fuel Administrator at Pittsburgh has stated that the operators are right in their complaint, and that the Pennsylvania R.R. has positively refused to accept coal for its engines from any source except the mines on its lines. This means that it will not accept coal from the Pennsylvania Lines West. The fuel administrator says in other words, "The Pennsylvania R.R. will not pay a freight rate of 65c. a ton. For this reason, I am furnishing the company 1152 cars of coal a week directly from mines along its road, much of it coming from the mines on the Pittsburgh, Virginia & Charleston division. It is the order of the Federal Fuel Administration, and all I can do is to obey. In my opinion it is neither right nor fair to the operators or the coke and byproduct concerns who badly need this grade of coal. But I am powerless."

Governor-elect William C. Sproul will be asked to incorporate in his inaugural message a recommendation for serious consideration by the Legislature of a proposition for state health insurance. This is among other sociological problems that will command attention of the state lawmakers this year. The success of the Workmen's Compensation Act and other humanitarian acts, it is declared, has convinced the larger interests that health insurance should be seriously considered.

In order to learn health conditions and the need for aid in the bituminous coal fields of this state, an investigation was made for the Health Insurance Commission in October, in Fayette, Washington, Westmoreland and Somerset counties. In the families of miners health conditions were found very poor. Prenatal care was virtually unknown; infant deaths were high, the rate in Fayette County being 160 per 1000 living births. Deaths from children's diseases were high. The commission found it interesting to note the contrast between the lack of care for the sick and the elaborate systems maintained by the coal companies to handle accident cases.

Charleston, W. Va.

Until Christmas week the car supply in the Fairmont region had been away below par, and just at a time when cars were needed. But during Christmas week, for some reason or other, the supply took a sudden spurt and empties began to accumulate, with a supply of over 2000 on hand the first day of the week. Despite the Christmas holidays and a general tendency to suspend operations, much coal was loaded, everything considered. Th was necessary owing to the fact that some of the larger companies had got behind with their orders, and also because of a steady demand from the Reading and other Eastern roads for railroad fuel. More miners are needed in the Fairmont field. Taken as a whole, the demand for Fairmont coal is rather brisk at this time—much more so than would naturally be expected.

Production in the Kanawha district has sagged considerably, yet not below, or at least not much above, the demand. An extremely quiet market is looked for until toward the end of January, and in the meantime operators are marking time. There was, however, during the week ending December 28, so far as reported, a total tonnage output of 42,065 tons.

"No market" crept into the last report of production in the Pocahontas and Tug River districts, and a loss of 3577 tons is shown from that cause alone out of a total tonnage loss of 97,992. It was also apparent that a car shortage was cutting down production, since a loss of 46,950 tons was sustained through that cause alone. The total output was only 360,567 which is the lowest figure for the year. Some of the mines in the Pocahontas field have cut down their operations to three days a week. It is stated that only a few days ago there were 5000 unreconsigned coal cars loaded between Bluefield and Cincinnati. The western boundary for the shipment of Pocahontas coal has been extended to include Cincinnati. Operators in the Pocahontas field are inclined to believe that the present lull will be of short duration.

Inability to secure ship facilities has caused a reduction of the output of the New River district. Embargoes have been in effect since Dec. 19 on tidewater coal, and the number has been considerably augmented since that time so that little or no coal is going to the seaboard. At the last of the year the market for New River coal is far below normal.

Deep dents were cut in the output of the Guyan region during the last week of December principally because of no market for the coal of the district, the loss from such a cause being 140,432 tons, or 54.68 per cent. of the total full time capacity of the district, the production loss, all told amounting to 72.44 per cent. of the total full time capacity or in tons 186,044, leaving a production of only 70,781 tons or 27.56 per cent. The "no market" loss reflects the generally unsatisfactory market conditions.

Birmingham, Ala.

A slight falling off in the coal output of the Alabama district is reported for the past week, due to holiday celebrations. The production for the last month of the year 1918 has not been satisfactory. For the week ending Dec. 7 the output was 381,065 tons; for the week ending Dec. 14, 387,430 tons, and for the week ending Dec. 21, 367,632 tons. There is still unsteadiness in labor, but the influenza epidemic is about over. There is hope that the return of men from the cantonments and army camps will alleviate the situation to a great extent. The pinnacle of production was reached the week ending Aug. 24, when 430,311 tons were mined.

Coal men of the district are optimistic regarding the operations of the next few months, and, in fact, the entire year. They state that the demand for all kinds of fuel will not be met for months to come. Coke production is still far under the demand. Producers and dealers in coke say that good prices obtain and that there is a ready market for every ton that can be supplied.

Seattle, Wash.

Considerable activity is manifested in the coal regions of Alaska, now that the Government railroad is completed to practically all the more important districts. The Alaskan Engineering Commission recently let contracts for the delivery of 6000 tons of Nenana coal from properties recently opened on the line of railroad, 29 and 44 miles south of Nenana. This marks the beginning of real development in Alaska's vast interior coal fields.

One hundred tons of coal are being produced daily at the Eska mine, in the Matanuska coal fields, by the Alaskan Engineering Commission, which is employing about 150 men at this place. The commission is also employing about 40 men in development work at Chickaloon. This is the property from which the coal, secured and tested by the United States Navy, was found to be the equal of Pocahontas coal for steaming purposes. The Chickaloon Coal Co. is actively pushing drilling and other exploration work on its lease area, adjacent to Chickaloon. The Bering Coal Co. has taken a lease in the Bering coal fields and has a large force engaged in extensive development work.

The Alaskan Anthracite R.R., under construction from Comptroller Bay to the coal property of the Alaskan Petroleum and Coal Co., was completed to tidewater on Bering River, Oct. 7, 1918. It is planned next season to extend this railroad seven miles from Okalee channel on Comptroller Bay, which will permit direct loading on to ocean carriers.

PENNSYLVANIA

Anthracite

Natalie—Madeira, Hill & Co. are improving this mining village by the addition of a number of miners' houses, built of cement blocks.

Lansford—The Lehigh Coal and Navigation Co. will soon begin the stripping of the overburden on a large track located between Summit Hill and Lansford.

Bethlehem—The official employees of C. M. Dodson & Co., Beaver Brook, Locust Mountain Coal Co., Shenandoah, and some former employees of Morea Colliery, together with the "soft coal" officials of Weston, Dodson & Co., were entertained by General Manager J. B. Connell in the firm's new office building, recently placed in service at this place. Addresses were made by the heads of departments and by two returned heroes of the war.

Hazleton—December was a rainy month. Many collieries were hampered by high water. At the No. 21 slope of the Lehigh & Wilkes-Barre Coal Co., the pumping plant failed and men and mules were hastily withdrawn to avoid an accident. The many "worked out" strippings on the Lehigh & Wilkes-Barre, Honey Brook division, make the handling of water a serious matter.

Rents of employees' homes on the O. B. Markle Co. property, which were reduced one-half during the war, were placed at the original figure beginning Jan. 1.

Bituminous

Pittsburgh—The Pittsburgh Coal Co. has contracted with the Roberts & Schaefer Co. for a Marcus screen to be installed in the Montour No. 10 tipple.

WEST VIRGINIA

Bell—The Carter Coal and Mining Co., having erected its own power station in connection with its plant at this place, will put the new plant in commission within the next few days.

Madison—The Spruce River Coal Co. contemplates within the near future a number of improvements at its plant near here and among other things has provided for the installation of a 2200-volt transmission line.

Omar—The Main Island Creek Coal Co. has recently completed its new store and Y. M. C. A. building at its Barnabas plant. The building was designed by Mr. Martin, who is manager of the company's operations at Amherstdale, W. Va. The cost of construction and equipment was approximately $75,000, and no pains nor means have been spared to make the building complete.

Welch—The bodies of Fred Paulick and Martin Verseskia, the two men who were killed in the Havaco mine explosion Saturday morning, Dec. 21, have been found and were brought to Welch to be prepared for burial. The theory has been advanced that a door leading into the mine passage had been left open, and gas accumulated, and when the electric motors went in they made sparks which set off the gas, causing the explosion. The damage done to the mine has not been estimated, but it is placed at a considerable figure.

Williamson—James Hatcher, one of the best known men of Pike County, Kentucky, began breaking ground on his mineral lands near Keyser, on the Big Sandy division of the Chesapeake & Ohio Ry., on Jan. 1, 1919. This property consists of 3200 acres of high grade splint and gas coals, and is underlaid by five workable seams of coal aggregating 25 ft. in thickness. Mr. Hatcher is contemplating making further railroad extensions, and about 1½ miles of grading is already completed. Eventually four miles will be opened on this property. Timber necessary for the construction of additional tipples and other mine buildings is being cut from this same property. A double tipple is planned for mines Nos. 2 and 3. All mines will be electrically equipped throughout. It is planned to construct 100 modern miners' homes, twelve of which are already completed, also a three-story store and office building

KENTUCKY

Bourbonville—Three large coal companies are making extensive development in the Harlan field. They are the United States Coal and Coke Co., the Wisconsin Steel Co., subsidiary of the International Harvester Co., and the Black Mountain Coal Co., which is said to be one of the Peabody interests. These three concerns are developing approximately 200,000 acres of fine coal lands in that field.

ALABAMA

Birmingham—Chief Mine Inspector C. H. Nesbitt has called a meeting of the board of examiners, to be held in his office in the Chamber of Commerce Building, Jan. 20 to 23 inclusive, for the examination of applicants for positions as mine foremen and firebosses. An unusually large class is expected, as this will be the first session of the board held since January, 1918, the meeting scheduled for July, 1918, having been passed to avoid any possible interference with coal production during the war.

INDIANA

Evansville—A report from Evansville, Ind., Dec. 29, stated that an attempt had been made to destroy the plant of the Crescent Coal Mining Co., near Evansville, by setting fire to the washhouse. John Patterson, night watchman, attempted to turn in an alarm and was assaulted by an unknown man, who escaped.

ILLINOIS

Belleville — The Beese Coal Co. has been incorporated by John Beese, Sr., John Beese, Jr., W. F. Hoehner, Charles Beese, W. G. Hoehner and C. A. Hoehner.

Springfield—Meetings of the Illinois State Mining Board will be held in January as follows: Jan. 9 and 10, at West Frankfort; 11, at Herrin; 13, at Belleville; 14, at Collinsville; 15, at Staunton; 16, at Springfield; 18, at Danville; 20, at Peoria; 21, at Canton.

O'Fallon.—Six hundred miners in the so-called Nigger Hollow Mine No. 2 of the St. Louis & O'Fallon Coal Co. were temporarily thrown out of work when fire was discovered in one of the entries of the mine. Men were put to work immediately to wall in the fire. It is expected that the flames will be smothered without difficulty.

Collinsville — The new labor temple, erected by the four miners' unions of Collinsville at a cost of $100,000, was dedicated on Sunday, Dec. 29. There was a parade and addresses by Thomas J. Reynolds, Illinois District Arbitrator of the United Mine Workers; Dan Thomas of O'Fallon, sub-district president; Frank Farrington, of Springfield, district president, and Frank J. Hayes, international president.

KANSAS

Scammon—The Carbon Coal Co. No. 2 is completing what is said to be the largest stripping mine in Kansas. The operation is south of Scammon and is located on a 320-acre tract of land. The present equipment consists of one No. 225 Bucyrus shovel and one Bucyrus loading machine. Present capacity is 600 tons per day. Equipment will be doubled shortly and the output increased to 1200 tons daily. W. A. Patterson is president; R. A. Gray, vice-president, and W. C. Shank, secretary and treasurer. General offices of the company are at Pittsburg, Kan.

Foreign News

Merritt, B. C.—At the Diamond Vale mine a tipple is being constructed in order to permit an early resumption of operations. The mine has been idle for some time.

Vancouver, B. C.—The International Coal and Coke Co., incorporated in the State of Washington, of which A. C. Flummerfelt, of Vancouver, is president, will reincorporate in Canada in order to save double taxation. It is capitalized at $3,000,000, and shareholders are being offered an even exchange of new for old shares, or 25c. in cash for shares of the par value of $1.

Nanaimo, B. C.—The Granby Consolidated Mining, Smelting and Power Co., Ltd., has recently put into operation its new Marcus tipple at Cassidy. This company will also erect a large coal washery, to be built in connection with the tipple, for the finer sizes. Contract for the tipple equipment was placed with Roberts & Schaefer Co., of Chicago, who also have been awarded contract for the new washery equipment.

Vancouver, B. C.—It is reported that the use of powdered fuel by the B. C. Sugar Refinery has proved satisfactory and that, as a result, the Powell River Pulp and Paper Co. and the Ocean Falls plant of the Pacific Mills, Ltd., are likely to adopt the same system. It is said that powdered fuel has been shown to be more economical than oil in this Province, and if the development suggested takes place there will be established an important additional market for the output of the coal mines of Vancouver Island, Merritt and Princeton.

Ottawa, Ont.—In order to enable the Nova Scotia Steel and Coal Co. to operate its submarine coal areas underlying Sydney harbor, which are only accessible through the intervening territory of the Dominion Coal Co., the Canadian Government has authorized them to enter upon and mine two portions of the Dominion company's leasehold, one about 4000 x 1000 ft. and the other about 8000 x 500 ft. The Nova Scotia Government is to receive the usual royalty of 12½c. per ton, and compensation is to be paid quarterly to the Dominion Coal Co., as the Government may determine. This action is taken under the powers conferred on the Government by the War Measures Act, on the recommendation of C. A. Magrath, as Director of Coal Mining Operations in Nova Scotia and New Brunswick. It is regarded as settling an important principle that operating mining companies cannot be deprived of access to their properties so long as payment is made for any trespass involved.

Personals

Lieut. J. R. Crowe, Jr., will shortly return to civil life and assume his former position as president of the J. R. Crowe Coal Mining Co., Kansas City, Mo.

Kerr W. Rittenhouse, who has been sales manager for the Central West Coal Co., Columbus, Ohio, for several years, has resigned to take a similar position with Consolidated Mining Co., also of Columbus.

Willis H. Brown, who has been out of the coal business for nearly a year because of illness, has opened an office on the 11th floor of No. 1 Broadway, New York City. He is well known to the trade, having been formerly connected with the Skeele Coal Co. and the Seiler-Rogers-Brown Co. He was a vice president of the latter concern.

Wiley L. Byers, general sales manager for the Producers' Coke Co., Uniontown, Penn., on Jan. 1, 1919, retired from active duty in that capacity after 6½ years of efficient service. During the war Mr. Byers has been assistant district representative and production manager of the Federal Fuel Administration, and was responsible in a very large measure for the wonderful record shown by the Connellsville coke region. Early in the spring Mr. Byers expects to enter business for himself, continuing in the coal and coke industry.

Obituary

Patrick Hogan, general superintendent of the Big Creek Coal Co., Canton, Ill., died recently. He was formerly a state mine examiner.

Louis Ray Kortkamp, of the Kortkamp Coal Co. died at his home at Hillsboro, Ill., after a short illness. He was the son of Louis Kortkamp, who was killed in the Kortkamp mine two years ago.

Robert L. Ralston, a prominent coal operator of southeastern Kentucky, dropped dead in a drug store in Middlesboro, Ky., on the evening of Jan. 1, while waiting for the city papers to come in on a late train. Mr. Ralston and several friends were discussing coal and other conditions, when he suddenly reeled and fell before he could be caught. He died before medical aid reached him, death being due to heart trouble. Mr. Ralston is survived by a wife and six children.

Coming Meetings

American Wood Preservers' Association will hold its annual meeting Jan. 28-29, 1919, at St. Louis, Mo. Secretary, F. J. Angier, Baltimore, Md.

American Institute of Mining Engineers will hold its 119th meeting Feb. 17-20, 1919, in the Engineering Societies' Building, New York City. Secretary, Bradley Stoughton, New York City.

American Society of Civil Engineers will hold its annual meeting Jan. 15-16, 1919, at the headquarters of the society, 33 West 39th Street, New York City. Secretary, C. W. Hunt, New York City.

Trade Catalogs

Copies of the catalogs, booklets and other literature listed below may be obtained free of charge by addressing the manufacturer.

Draeger 1917 Model Breathing Apparatus. Draeger Oxygen Apparatus Co., Pittsburgh, Penn. Two-color postcard folder illustrating and describing the new safety and comfort features of the latest model apparatus.

Coal Mine Car Bearings. Hyatt Roller Bearing Co., New York, N. Y. Bulletin 375. Pp. 12, 8¾ x 11 in., illustrated. Outlines the engineering advantages of the use of Hyatt roller bearings in coal mine cars.

Link-Belt Equipment for the Handling and Preparation of Coal at the Mine. Link-Belt Co., Philadelphia, Penn. Book No. 333. Pp. 88, 6 x 9 in., illustrated. Describes coal tipples, conveyors, washeries and other equipment used at the mines.

American Ring Coal Crusher. American Pulverizer Co., St. Louis, Mo. Pamphlet. Pp., four, 8½ x 11 in., illustrated. Describes a coal crusher that the manufacturer states uses less power and less labor than other like machines. The company guarantees the machine and takes all risks for wear and tear.

Lidgerwood Steam Mine Hoists. Lidgerwood Manufacturing Co., New York. Catalog. Pp. 32, 9½ x 12¾ in., illustrated. Presents the company's standard lines of steam mine hoists, and also a few types developed to meet special conditions. General specifications are given and tables of sizes, etc., for the different types illustrated.

C-H Mine Duty Self-Starters. Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Publication 408. Pp. 2, 8½ x 11 in., illustrated. Leaflet describes two types of mine duty self-starters, and draws attention to the need of installing automatic motor starters of this type for controlling pump and fan motors. A C-H unit charging rack for miners' electric lamps is also illustrated.

Miscellaneous Applications of Electrical Heat by Means of Standardized Units. Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Pamphlet. Pp. 4, 8 x 11 in., illustrated. Describes the C-H space heaters and makes special mention of the great variety of applications of these units. A blueprint accompanying the pamphlet gives all the dimensions of these standardized units.

V. V. Fittings. V. V. Fittings Co., Philadelphia, Penn. Catalog No. 21. Pp. 128, 8½ x 11 in., illustrated. A beautifully printed catalog listing the company's conduit fittings and safety switches. The pictorial index, occupying the first 13 pages in the book, affords the user of the catalog at once a visual and descriptive aid of the article he seeks information about, and should prove a valuable feature to prospective buyers of equipment.

Industrial News

Cleveland, Ohio—The Valley Coal Co. has increased its capital from $20,000 to $50,000.

Toledo, Ohio—The Rotal Elkhorn Coal Co. has increased its capital from $25,000 to $50,000.

Ohiopyle, Penn.—The Jim Run Coal Co. is preparing to erect some new bungalows at its mines near Ohiopyle.

Lexington, Ky.—The Barwick Coal Co., capital $35,000, has filed amended articles increasing its capital to $50,000.

Indianapolis, Ind.—The Panhandle Coal Co., of Indianapolis, has increased its capital stock from $200,000 to $400,000.

Niles, Ohio—The Niles Fuel and Supply Co. has been chartered with a capital of $10,000 by Charles H. Mason and others.

Chavier, Ky.—The Reckie Coal Co. has filed notice of an increase in its capital from $10,000 to $35,000, to provide for expansion.

Tyrone, Ky.—With a capital of $6000, the Tyrone Coal Co., has been incorporated by Albert Ledridge, A. J. Nowling and A. M. Nowling.

Pineville, Ky.—The Indian Creek Coal Co. has filed notice of an increase in its capitalization from $25,000 to $50,000 to provide for expansion.

Hazard, Ky.—The Midland Mining Co. has filed notice of an increase in its capital from $150,000 to $190,000, for proposed extensions and expansion.

Middlesboro, Ky.—The Block Coal Co., Middlesboro, Ky., capital $3000, has been incorporated by G. P. Sharp, James D. Yarborough and H. A. McCamy.

Newark, Ohio—The Eagle Mining Co. has been chartered with a capital of $10,000 by J. Howard Jones, Roderic Jones, Laura V. Secrist, George Hayden and Ray Patterson.

Canton, Ohio—The North Industry Coal Co. has been chartered with a capital of $50,000 by E. J. Condon, John Flueras, Constantin Westemean, Clude A. Volzer and Nick B. Alba.

Philadelphia, Penn.—The Atlantic Fuel Co., Fifty-second and Whitby Streets, has awarded a contract for the erection of a new one-story coal pocket at its works, about 30 x 125 feet.

Farmersburg, Ind.—The Barnhart Coal Co. has been incorporated with a capital of $25,000 to engage in coal mining. The directors are Frank Barnhart, Norman W. Freeman and Daniel C. Voreis.

Toledo, Ohio—The Nelsonville Coal Mining Co. has been chartered with a capital of $25,000 by William H. Albrecht, Jr., John R. Calder, George E. Seney, O. S. Brumback and John M. Ormond.

Regina, Ky.—The Winston-Elkhorn Coal Co., capital $200,000, D. R. Coleman, W. M. Coleman and others, plans large developments, operating four mines with shipping facilities over the Chesapeake & Ohio Railroad.

Columbus, Ohio—The Flint Coal Co. is the name of a new mining concern which has opened offices in the Columbus Savings and Trust Building with L. F. Bertrau in charge. The operation is on the Baltimore & Ohio, near McArthur, Ohio.

Philadelphia, Penn.—The Government, Navy Department, has awarded a contract to the Wark Yardley Co., 1737 Filbert St., Philadelphia, for the construction of a new coal- and ash-handling plant at the League Island Navy Yard, to cost $9435.

Philadelphia, Penn.—Walworth Manufacturing Co. has recently purchased the business of Hunter & Dickson Co., at 241-247 Arch St., and will operate it as one of its branches. The Walworth Manufacturing Co. manufactures valves and fittings for steam, water and gas work.

Huntington, W. Va.—The Vanbail Coal Co., 825 Fourth Avenue, recently incorporated with a capital of $50,000, has perfected its organization, and is planning for the early development of approximately 600 acres of coal properties. It is proposed to have a daily capacity of 500 tons.

Columbus, Ohio—The Hamilton Manufacturing Co. has installed one of its new stripping conveyors at the operation of the Vinton-Jackson Coal Co., in Vinton County, Ohio. This machine is the invention of William E. Hamilton of Columbus, and is reported to be doing good work.

Louisville, Ky.—The Seaboard Airline Railroad Co., which has been taking a considerable tonnage of eastern Kentucky coal, has cancelled all orders, being filled up with enough coal to last for several weeks. The Louisville & Nashville has also quit buying, and the Southern is almost filled up

Pittsburgh, Penn.—The Producers Fuel Co. has been organized to handle the output of coal operators as exclusive selling agents. Executive offices have been opened in the First National Bank Building. Officers of the company are J. K. Barber, president; W. S. Buyers, vice-president; R. C. Masten, treasurer.

Chattanooga, Tenn.—The Raccoon Coal Co. has filed articles of incorporation with a capital of $50,000 to develop coal properties in Wauhatchie Valley, near Kelly Ferry. It is proposed to install complete mining equipment, with a large new tipple. C. H. Huston, C. W. Howard and J. S. Fletcher head the company.

Preston, W. Va.—The Nethkin Coal Mining Co. has been incorporated with a capital of $100,000 to develop extensive coal properties near Newburg. W. R. Nethkin, Cumberland, T. R. Nethkin, Buckhannon, C. H. Lantz, Piedmont, W. Va., and H. C. Thompson, Philadelphia, Penn., are interested in the new organization.

Shenandoah, Penn.—The Wentz interests, operators of mines at Upper Lehigh Hazle Brook, Midvalley and Maryd, have acquired a mine at Raven Run. D. B. Wentz, president of the Wentz companies, applied for a charter for the new company, which will be called the Raven Run Coal Co. The plant will be located near Shenandoah, Penn.

Morgantown, W. Va.—The Davis Fuel Co. announces that it has changed its corporate name to Fiedler-Davis Fuel Co. in order to avoid confusion with other firms and corporations that bore names similar to the discarded name of the company. The change became effective Jan. 1. There has been no change in the personnel, capital or policy of the company.

New York, N. Y.—Charles S. Allen, secretary of The Wholesale Coal Trade Association of New York, reports that the Coal Exchange recently opened by the association is meeting expectations. About 25 transactions have been consummated through the Exchange, ranging from a few cars to 5000 tons. The members of the association are urged to avail themselves of the facilities offered.

Jeff, Ky.—The Acup Creek Coal Co., recently incorporated with a capital of $175,000, has been organized with Arthur L. Ware as president, John C. Eversole vice-president and Harry P. Jones, secretary-treasurer. The company is planning for the immediate installation of the necessary equipment for the development of about 2000 acres of coal properties, to have a capacity of about 1500 tons daily.

Buffalo, N. Y.—J. Fred Morlock reports that he has lately taken control of the mines of the Clarion & Allegheny, Pittsburgh & Allegheny and Cambria & Allegheny coal companies, in the Allegheny Valley and nearby districts. They have a total output of about 500 tons daily. The Cambria is a Lilly smithing variety. Mr. Morlock also has some other mines in that vicinity, which he took over some months ago.

Manchester, Ky.—The Columbia-Panama Coal Co. has recently acquired title to a total of 1300 acres of coal properties in the Manchester section and is understood to be planning for early development. It is said that the company is planning for extensive improvements and additions at its properties north of Manchester, including the erection of machine and repair shops and a new power plant for operation. H. H. Hardinge, Chicago, Ill., is president.

Buffalo, N. Y.—The Donner-Union Coke Corporation has filed plans for the erection of a number of new additions to its plant, to provide for increased capacity, aggregating in cost a total of about $300,000. Included in the structures are a new brick and steel product building, estimated to cost $100,000; service building, brick and steel, to cost $23,000; brick and steel machine shop, to cost $17,000; and reinforced-concrete coal bin to cost about $100,000, with auxiliary structures.

Bourbonville, Ky.—The Louisville & Nashvill R.R. is preparing to construct about 50 miles of new line in southeastern Kentucky to open up large coal fields. It is also announced that the same company will double-track that portion of the Cumberland Valley division between Corbin and Pineville in order to expedite the movement of coal trains. A section of the Harlan branch will also be double-tracked. That portion extends from Pineville to Paige, a distance of 18 miles. Large yards will also be built at Nolan and Baxter in the Harlan field. Construction work will start in the near future.

Dallas, Tex.—The coal output for Oklahoma during the month of November amounted to 368,225 tons, according to a statement recently issued by P. A. Norris, State Fuel Administrator for the State of Oklahoma. This is 16,273 tons in excess of the output during November, 1917. Mr. Norris also gave statistics showing that the coal production in the States of Arkansas, Missouri and Kansas showed a decrease for November this year as compared with November of last year, but that Texas showed an increase of 36,101 tons. It was shown that local industries and domestic consumers absorbed the increased production in Oklahoma, the railroads demanding less fuel than a year ago.

Clarksburg, W. Va.—Open-top cars are no longer available for team-track operators who are loading from wagon mines, according to instructions received Saturday, Dec. 28, from the office of C. W. Van Horn, superintendent of the Monongah division. Eastern shipments may be resumed at once. The circular letter announcing this change reads as follows: "Cancel previous instructions and effective at once and continuing until further notice discontinue entirely permitting open-top cars to be loaded at wagon mines or team tracks with coal. Also cancel instructions prohibiting coal loaded by wagon mines at team tracks to go forward to points east of Grafton. Permit such shipments to go forward either east or west unless specifically covered by other embargoes."

Jefferson City, Mo.—A bill for a workmen's compensation law, proposed by the Missouri State Federation of Labor, was introduced at the opening of the State Legislature on Jan. 8. It provides for the creation and management by the state of a fund to furnish insurance under the law at cost. The proposed law would be elective and not compulsory. If both employer and employees accept it, the employer will be liable irrespective of negligence for accidents arising in the course of employment. The schedule of benefits provides that in addition to all other compensation an injured employee shall receive all necessary medical aid for the first eight weeks, not exceeding $200, and in exceptional cases the commission may extend both of these limits. During temporary total disability the employee would receive two-thirds of his average wages until he is able to work again, but not longer than 400 weeks. During temporary partial disability he would receive two-thirds of his loss in wages until he is able to earn full wages again. For permanent total disability he would receive two-thirds of his average wage for the rest of his life. For permanent partial disability, after he is able to work again, the employee would receive two-thirds of his average wages for periods varying with the nature of the injury. If injury causes death, the employer must pay the reasonable burial expenses, not exceeding $200, and total dependents would receive two-thirds of the average wages for 300 weeks, to be immediately commuted and paid in a lump sum.

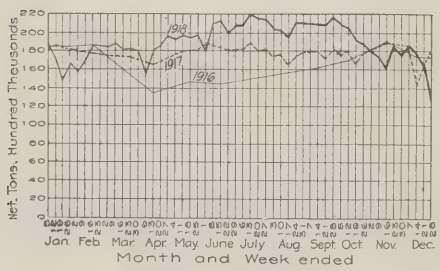
MARKET DEPARTMENT

Weekly Review

Market Conditions Still Stagnant, With No Hope of Improvement in Near Future—Output of Soft Coal Shows Tremendous Drop—Coal Industry Hopeful for Coming Year—Anthracite Situation Well in Hand.

MARKET conditions continue to be hopelessly dull. The lack of even the slightest buying sentiment proves only too conclusively that industrial plants are stocked with coal to an unprecedented extent. Many in the trade prophesy that it will be weeks before buyers evince any eagerness to contract for their future requirements.

The production of soft coal has dropped considerably, owing to the observance of the Christmas and New Year holidays. Figures compiled for the week ended Dec. 28, 1918, show that the output of bituminous coal during this period was the lowest in three years. Only 6,385,000 net tons were mined, which is 3,746,000 net tons behind the production of the week ended Dec. 21, 1918, and 3,352,000 net tons lower than the output during the Christmas week of 1917. The total production of bituminous coal for the period Apr. 1 to Dec. 28, 1918, is estimated at 447,748,000 net tons, an increase of 35,187,000 net tons over the output of the same period in 1917.



In spite of the falling off in production, shippers and dealers display no apprehension or uneasiness. Efforts at speeding up the miners during the war period resulted in an overstocked market the moment war industry ceased, and the net effect of the diminished output at this time will be to steady the market. Some little price cutting is reported, though the Government figures are being adhered to rather generally. The industry is looking forward to the entire elimination of Government control of coal, the consensus of opinion being that the regular channels of trade can now be depended on to take care of the country's needs.

No reports are at hand of a serious anthracite shortage anywhere, unlike the state of affairs at this time last year. In fact so favorable has the situation become that the Government has signified its intention of relinquishing control of anthracite distribution in the near future. All restrictions on the use of the steam sizes of hard coal have already been removed, and this will doubtless help the movement of the egg and pea sizes, which are fast becoming a drug on the market. Stove and chestnut are still scarce, but even the proportion of these two anthracite coals will grow larger soon, as Government requisitions are being cancelled.

The observance of the Christmas holidays caused hard coal production to fall off more than a half million tons during the week ended Dec. 28. The total output of anthracite for the period Apr. 1 to Dec. 28, 1918, is estimated at 73,830,000 net tons, or 1,606,000 net tons below the output of the similar period in 1918. This tonnage is rather gratifying when it is remembered that the hard coal regions have been severely handicapped by a shortage of labor throughout the year.

WEEKLY COAL PRODUCTION

The lowest weekly production reported in the last three years was brought about by the time lost on account of the Christmas holidays during the week ended Dec. 28. Estimates for this week place production at 6,385,000 net tons, 3,746,000 net tons or 37 per cent. behind production of the week ended Dec. 21, and 3,352,000 net tons or 34 per cent. behind production of Christmas week of last year. The average daily production for the current week (five days) is estimated at 1,277,000 net tons as

compared with 1,913,000 net tons for this coal year to date and 1,763,000 net tons for the same period of 1917.

Total production of bituminous coal for the period Apr. 1 to Dec. 28 is estimated at 447,748,000 net tons as against 412,561,000 net tons during the period Apr. 1 to Dec. 28, 1917, or an increase of 35,187,000 net tons.

The production of bituminous coal and lignite in the calendar year 1918 is estimated at 585,883,000 net tons, an increase compared with 1917 of 34,092,000 net tons or 6.2 per cent. Four states reported decreases, Georgia, Iowa, Missouri and Texas. The most important increases were in Pennsylvania, 11,264,000 tons; Ohio, 5,715,000 tons; Illinois, 5,064,000 tons; and West Virginia, 4,908,000 tons. The estimates indicate that West Virginia still retains second place as a coal producer, but the lead is so small that final returns may place Illinois in this place, assumed by West Virginia in 1908.

The loss of time brought about by the Christmas holidays caused anthracite production during the week of Dec. 28 to decrease more than a half million net tons, compared with the production of the week preceding, and was approximately 200,000 net tons lower than the production during the corresponding week of 1917. For the period Apr. 1 to Dec. 28, the production of anthracite is estimated at 73,830,000 net tons, which is 1,606,000 net tons or slightly over 2 per cent. below the production of a similar period of last year.

Carriers' reports for the week ended Dec. 28 show tremendous decrease in loading in all districts, not only compared with the week of Dec. 21, but also with the week of Dec. 28, 1917. In central Pennsylvania, the decrease in cars loaded amounted to approximately 12,000; in Ohio, 7800; in the district including northeast Kentucky and southern West Virginia, 12,100; in Tennessee and Kentucky, 6400; in the district including Illinois, Indiana and western Kentucky, 9500; and in the district including Iowa, Texas and the southwest states, 4000.

Bituminous coal shipments to New England during the week of Dec. 28 are estimated at 242,443 net tons as compared with the previous week's shipments, amounting to 258,247 net tons. An increase occurred during the week in rail receipts while tidewater shipments decreased from all harbors.

Tidewater shipments decreased approximately 10 per cent. during the week of Dec. 28 and are estimated at 583,072 net tons. A decrease of approximately 20 per cent. or 78,000 net tons, occurred in shipments from New York and Philadelphia with a slighter decrease in shipments from Baltimore. An increase of approximately 16,000 net tons or 8 per cent. occurred in shipments from Hampton Roads.

The production of beehive coke in the United States fell 130,000 net tons during the week of Dec. 28 compared with the week preceding, due generally to the loss of time on account of the Christmas holidays. The preliminary estimate places production during the week at 441,000 net tons as against 567,000 net tons during the Christmas week of 1917. The plants of operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania were operated during the week of Dec. 28 at 68.2 per cent. of their full time as compared with 73 per cent. during the week ended Dec. 21.

Byproduct coke production of the United States declined during the week of Dec. 28 approximately 16,000 net tons or 3 per cent., compared with the week preceding, and is estimated at 565,586 net tons. This production, however, exceeded that of the week of Dec. 28, 1917 by 136,722 net tons, or approximately 25 per cent. The limiting factor during the present week was lack of market in Pennsylvania. In addition, approximately one-quarter of the time of the Alabama ovens was lost on account of plant repairs. The plants of the country were operated during the week at 87.4 per cent. of their full time as compared with 89.4 per cent. during the week ended Dec. 21. The operators of the country were able to secure for the first time, during the week of Dec. 28, all the byproduct coal that was needed for their full time operation.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods was less than for the corresponding week a year ago. Road sales for both immediate and future delivery also were less. Many buyers were in the market on Monday and Tuesday seeking merchandise for January sales. Summarizing holiday business, retailers report that the total was excellent. Collections are normal.

Dry Goods Economist—Unusual interest is shown in various lines of dress cottons, because of lack of confidence on the part of buyers in the ability of mills to supply appreciable quantities of wool or worsted dress goods for some time to come. The raw-cotton situation is unsettled. Domestic mills are not buying, and exports are less than had been expected. In the gray-goods market, reductions of from ¾ to ¼c. per yard were made on some goods, while others advanced. The woolen goods situation is growing more acute.

American Wool and Cotton Reporter—That the wool market is more or less artificial is evident. Apparently every effort is being made to cancel the quantity of Australian wool which has been contracted for, but there is some question as to the ability of the Government to get out from under this contract, since it represents a good profit to the British Government, and it is understood that the British Government is not inclined to take back such a large amount of wool, when there is such a large oversupply on hand, and it may be hard to dispose of it. Cotton remains firm. There is a prospect that foreign countries will want cotton, which is a big factor in the strong situation. Another bullish factor is the fact that the present crop is the fourth short one in succession.

Bradstreet's—At the outset of the new year, following twelve months of record accomplishment, buying hesitates, skepticism as to the holding power of prices prevails, especially in the iron and steel industry, and inventorying still occupies attention; but, withal, advices as to potential demand for goods in general, at a price, of course, are rather liberally tinctured with optimism. In the larger lines stocks are light, shipments on old sales together with those going forward to eke out broken lines are quite large, but in a broad sense slack-water conditions prevail. Incidentally, the government continues to readju t contractual obligations, while assuring traders that unwanted supplies will not be thrown on the markets, and that foreign fields are likely to be sufficiently needy to absorb quantities of such commodities as the government holds.

The Iron Age—In every quarter the question of the readjustment of contracts to the lower prices adopted two weeks ago by leading sellers is uppermost. Pig iron producers set out to hold to the old prices, but in the past week the calls upon them for the revision of contracts have grown in numbers and in urgency. Some furnace companies seem inclined to yield, while others strenuously insist that contracts be carried out as written. The falling off of foundry operations is a factor to which more consideration is being given, however, and the adoption of the lower basis for pig iron has found more favor than was indicated a week ago. That some blast furnaces will not long operate with $3 taken from their market price is evident, and the readjustments in finished material will likewise impose some hard choices on high cost mills which must buy their raw materials in the market.

Atlantic Seaboard

BOSTON

Market extremely dull. Steamers being tied up. Somewhat increased movement all-rail. Railroads stop taking coal. Mild weather and curtailment in manufacturing have effect. No sign of new contracts. Changes in trade. Government price shaded, but only small tonnage offering. Hampton Roads dumpings light for New England. Difficult to arrange disposition. No indication of reduced prices on smokeless coals. Georges Creek comes forward only for smithing. Restricted market from New York piers. Anthracite continues to improve. New England fuel authorities loosen their hold. Broken, egg and pea in surplus everywhere. Steam restrictions off. Stove and chestnut still hard to get.

Bituminous—The New England situation continues practically without developments. The market is hopelessly dull and inquiry for any of the steam grades is practically nil. The accumulation is still so great throughout the territory that cancellations are general, and because it is next to impossible to replace these contracts the trade is suffering a very much reduced tonnage. Large plants which use up to 4000 or 5000 tons weekly are unwilling even to buy small lots at present prices. Buyers everywhere state their anxiety to get rid first of the inferior coal taken on during the rush in August and September. There have been so many cases of heating in storage that buyers are not to be blamed for their attitude.

An increasing number of steamers owned by the Emergency Fleet Corporation is being laid up in New England ports because of the lack of charters. All the rehandling factors have their trade so well filled up that there is only a very small outlet from week to week for such cargoes as arrive. In addition to that the Navy Department has more coal in storage here on private wharves than was ever known before, and this limits again the tonnage that can be absorbed by this market. The trade is much interested in what action the Shipping Board will take on coastwise freights. The present rate of $3.25 from Hampton Roads and $3.50 from Baltimore has been in effect since April, and it will not be many weeks before the trade will insist that the authorities make some statement of policy. As it is, the differential over all-rail rates is so great that all the coastwise shippers will be seriously hampered in any effort to place coal on contract. The Shipping Board, of course, has the matter in its own hands, and nothing but public opinion can force any reduction in rates unless the authorities turn back to their owners a sufficient number of steamers to affect the freight market. It is rumored that some of the largest ships withdrawn from the trade last year will be returned within a few weeks. Meanwhile, it is likely that the Railroad Administration will interest itself in this phase for the reason that so much railroad fuel is brought by water from Baltimore and from Hampton Roads.

An increase the past week in movement all-rail is largely due to railroad fuel coming forward on purchases made a month or so ago. Only in scattered instances is there any increase in the movement of commercial coal. Low output is still characteristic of most of the operations in central Pennsylvania, and for a month or two no heavier shipments are looked for. As for the railroads, all buying has ceased and probably will not be resumed until the present large reserves are worked down. All the New England roads have had very light traffic the past two months, and to such extent is this true that the Boston & Maine, for instance, is using 1000 tons less per day than a year ago. Contract shipments by water have been stopped and the steamers diverted on other business.

Mild weather and the curtailment in manufacturing of all kinds are having their combined effect. The textile centers especially show the result of this, and the day is simply postponed when there will be any active buying interest in coal for next season. There is every indication that when buying is resumed there will be more discrimination as to quality and shippers than we have known for at least three years. Practically all Government requisitions through the several district representatives are now off, even for railroads and public buildings, and this will undoubtedly mean a new effort on the part of the shippers affected to place their coal in the open market. There are no signs of new contracts, however, and as yet there is no intimation what next season's price will be on high-grade coal.

The Government price has been shaded the past fortnight by shippers of medium grades; $2.80@2.90 has been freely quoted for spot coal, but the tonnage has been small rather than large, and there are few traces of actual sales. The railroads would naturally be among the first to get these offers, and it is a commentary on the general situation that each time a price is heard it is 5c. or so less than the previous quotation. And this is at a time when most of the mines are on 30 to 40 per cent. output. So far the highest grades that are open to bunker pools have not been shaded.

Clearances from Hampton Roads for New England continue light. Disposition at this end is increasingly hard to arrange, and the agencies are making every effort to place their coal in other directions. Bunker business, of course, is most attractive, and all the shippers who can get such business have a wide margin on which to go and come, before there is any question of reducing the regular f.o.b. price for cargo coal. Bunkers will not take care of all the coal that will shortly be pressing for outlet, and either the export market will have to be enlarged or the mines will be forced to curtail. Nothing comprehensive in the way of business can be looked for from New England for months to come.

Notwithstanding the removal of zone restrictions all-rail, Georges Creek is not coming forward any more freely than before, when it was restricted to the water route. It becomes increasingly evident that this once popular grade will be available for this territory only for forge purposes. The past year or so the largest proportion has gone for naval and special Government use, and it is quite likely that this coal, which once had the call in New England, will practically disappear as one of the steam grades.

Anthracite—Shipments continue to improve both by rail and water, and there is now practically no anxiety in any direction over continuing supplies. The "independent" shippers are actively soliciting orders, and shipments that were impossible to get two or three months ago are now coming forward in considerable volume. Retailers are so much encouraged that they are cancelling orders previously on file with such shippers, and for the balance of supply are looking to sources which they regard as more dependable in off seasons.

Mr. Storrow has announced that all active regulation on his part is now practically at an end. All but a few members of his staff have been dismissed, and except for clearing up loose ends there will be little done in his office from now on. His own resignation has been tendered to take effect at the pleasure of Dr. Garfield. "Emergency" coal has been reduced to five cars daily, effective Jan. 5, and it is likely that another week will see this movement discontinued. Four cars daily are being distributed in Maine and one car in Rhode Island. It is rumored that all allotments will be withdrawn by Jan. 15, and distribution will once more be in the hands of the regular shippers. There are now only a few cases where communities are seriously behind in their quotas, and these arrears can be promptly made up when the shippers themselves are left free to make deliveries at those points.

Broken, egg, and pea are in ample supply in most cities and towns. Stove and chestnut are still scarce, but the proportion has gradually increased as Government requisitions have been cancelled. In cargoes from New York ports the usual assortment now is egg, stove, chestnut and pea in about equal proportions.

It is understood that all restrictions on the use of anthracite for steam purposes are now taken off. This should help the movement of egg and pea sizes, which are fast becoming a drug on the market.

NEW YORK

The anthracite market shows little activity. Dealers are well supplied and demand is slow. No serious trouble expected in providing for needs for balance of coal year. Orders for Independent coals cancelled. Anthracite steam coals plentiful, with prices easy. Good supply of bituminous on hand. Demand slow except for high grades. Trade marking time and buyers hesitate.

Anthracite—There has been little activity in the local market. Dealers are well supplied with coal and, because of the unseasonable temperatures until the early part of this week, consumption has been slow. The trade does not now look for any serious trouble in the way of supplies during the balance of the current coal year unless there should be transportation difficulties. Although production figures do not show any increase, but on the contrary the reverse, there is enough coal being shipped here to take care of the demands made on the dealers and to enable them to get ahead on certain sizes.

Producers and shippers of Independent coals are beginning to feel the effects of the continued mild winter, by the refusal of retail dealers to either accept deliveries of coal or to place orders for more. Dealers find it possible with the supplies they now have to secure sufficient tonnage through the larger producers and to save the 75c. per ton they must pay for Independent product. As a result it is probable that nothing short of a decided change in temperature can keep the market for individual coal from breaking. Consumers are so well supplied that they are now particular as to getting the size they prefer and are refusing to take any other.

There was a further decline in the dumpings at the local Tidewater docks during the week ended Jan. 3, a total of 5546 cars having been dumped as against 5691 cars the previous week. For December the reports show that 26,261 cars were dumped here, as compared with 21,891 cars in November, an increase of 4370 cars.

The quantity of the individual sizes of domestic coals the various shippers and dealers have on hand depends considerably on their trade. Egg is plentiful with most shippers, while stove and chestnut are tighter, but not scarce. This is caused by local conditions, certain sections of the Greater City using more of one size than another, the retail dealers being governed entirely by such conditions. Broken, pea and No. 1 buckwheat are long, more of the first named size being in dealers' yards than is usually the case in this market.

There has been little movement in the small coals. All sizes are accumulating rapidly and demand is small. Buckwheat is plentiful, some shippers being so well stocked that it is reported concessions are being made to move it. The same can be said regarding rice and barley. These coals have been purchased in larger quantities than has been the case under ordinary conditions, with the result that many retail dealers have large stocks on hand.

Bituminous—Lack of demand for the fair grades and a continued good demand for the higher grades of bituminous coal continues. This condition does not affect all producers and shippers, but is general.

The threatened strike among the marine workers, and which did result in several hundred workers stopping work for a few days, was one of the reasons why embargoes were placed on shipments at St. George and Port Reading late last week. There is an accumulation of coal at these two docks and movement has been slow.

Reports show an increase in the dumpings at the local docks for the week ending Jan. 3, 5451 cars having been handled as compared with 5128 cars the previous week. During last month 25,169 cars were dumped as compared with 24,582 cars the month of November. Receipts here are not expected to show any increase for the next couple of weeks. The mines have not recovered from the holiday season, and as the Greek churchdays are ahead, added to the scarcity of labor, the disinterestedness displayed by some workers, and the falling off in car supply on some roads, the prospects for increased shipments are not bright.

That New England is in good condition is borne out by the resignation of Fuel Administrator Storrow, announced on Saturday, Jan. 4. Mr. Storrow, according to reports, stated at the time that the situation both as regards hard and soft coal was now satisfactory and might be left to ordinary channels for the rest of the winter.

The removal of price restrictions and their effect on the market continue to be one of the chief topics of conversation among the trade. Shippers are not inclined to bind themselves to contracts and will not do so until they know the exact situation. Some of the trade look for the discontinuance of the zoning system this month, to be followed almost immediately if not at the same time, by the removal of the price regulations.

The pools containing coal suitable for bunkers are well stocked, but the demand is good while the keen competition among the small operators tends to keep the quotations where they were last week.

PHILADELPHIA

Anthracite growing more plentiful. Moderate weather still holds back demand. All companies making good shipments. Individuals likely the first to be affected when market breaks, which seems imminent. Egg and pea draggy. Dealers showing signs of independence. Retailers start advertising. Bituminous well taken. Short production. Export business starting.

Anthracite—It is known that some shippers and many retailers are actually wishing for severely cold weather. It is also developing that many hours of unnecessary work were devoted to figuring allotments and percentages of increases and reductions in tonnages as based on previous shipments to various dealers. This is convincingly proved by the fact that the largest shipping company feared to enter January orders for its numerous customers based on the tonnages due them. Knowing the condition of the market here, it deemed it advisable in order to avoid having refused coal on its hands to write all to whom coal is due, asking if it was their desire to have orders booked for their allotments. Naturally the rejections were few, for it will not be the big companies, with their prices 75c. or 95c. below the smaller houses, who will be the first to have their orders suspended.

The operators are showing signs of being pleased with their success in mining sufficient coal and in its distribution to all markets, notwithstanding the loss of about two million tons due to the epidemic. We have interviewed many buyers who are inclined to believe that the unusually mild weather to date has saved the situation and not the elaborate system of distribution, with its figures and percentages. It is also stated that tonnage lost through the idleness at the mines was in realty not necessary on account of the lack of severe weather.

Several of the largest shippers frankly admit the situation is causing them concern, while some of the smaller houses like to appear optimistic. To date we have been unable to find where they have been cutting into the differential, but anything is likely to happen, and we are watching for a genuine slump. A representative of one of the big companies reports that unless it soon grows cold and stays cold the whole system of distribution will go to smash and there will be a wild scramble for business. Surely the days of great activity in the Fuel Administration are numbered.

This week saw the demand for egg and pea continue to grow less. Aside from a few suburban dealers, the trade is well covered on egg, while pea is flat in all sections of the city. Some shippers report that most of their trade is even fairly comfortable on stove coal, but the demand for it is still good and very far in excess of that for egg and pea. For some reason little chestnut, as compared to the other family sizes, has been coming here and we know many dealers who are extremely short of it. No dealer can be found who will say his trade will take coal regardless of size. Unlike a year ago, when the householders were grateful for coal of any size, they now insist on the size to which they are accustomed and will accept no other.

With coal getting easier dealers are already showing some signs of independence. They seem to realize that they may soon be again able to buy their coal where they want and not only where they did during the 1916-17 coal year. They are recalling that all shippers have not refunded the state tax for the last six months of 1915. While coal was so tight no one pressed his claim, but it has not been forgotten and the question is soon to be forcibly brought to the attention of some shippers when the time is more propitious.

The representative dealers are concerned as to how their smaller competitors will hold prices after the retail trade loses the controlling interest of the fuel authorities. They dread the return of price cutting with the devious methods of that practice. Just now they are greatly displeased with a suburban dealer who for some months received coal only through brokers and whose prices were correspondingly high. This week he received quite a substantial tonnage from one of the big companies, his entire quota for several months. Immediately he inserted an advertisement announcing in big type "Reduction in Prices." Although he was no lower than many of his competitors his "ad." was misleading and his method condemned. In this connection it is noticeable that an increasing number of retailers who formerly used newspaper space are again advertising. There is no mention of prices, most of them referring to service, and some others to the fact that they have all sizes of coal in stock.

When consulting one of the largest houses as to the status of the steam trade we were informed that the least said about it for publication the better. Unquestionably it is dull, and even the dealers who supply the small trade are complaining. The only desirable size is buckwheat, and we believe all shippers are able to dispose of their entire tonnage of this size; but the other sizes are becoming a greater problem with each day.

Bituminous—There is a firm demand for all coal coming into the market. Shippers continue to report only a moderate car supply and a shortened production due to the holidays which is making itself felt with full force at this time. The railroads continue to pile up reserve stocks of motive power fuel, which still causes much difficulty to supply the commercial demand for high grade fuels. There is no tendency to price recession, as coal continues in good demand, and this is especially so since there is some indication of foreign export business starting in good volume very shortly. It is understood that several foreign cargoes are already contracted for.

BALTIMORE

New year begun with a number of problems yet to be solved but a plentiful supply of soft coal pouring in. Embargo necessary at times at Canton pier. Good run of hard coal with a decreasing demand. Nut only real scarcity.

Bituminous—The coal trade here is off on a new year with every feeling of confidence, although it is realized that many matters must be adjusted before a stable basis for trading is set. For the present there is a plentiful supply of coal pouring in. Indeed the rush was so great the past week that all the fuel was not absorbed promptly, and a brief embargo had to be placed against the Canton coal pier, where fuel from the Pennsylvania, Baltimore & Ohio and Western Maryland is concentrated under Government control for harbor delivery. Numerous industrial sidings also have been congested recently, and the railroads were busy urging more prompt unloadings.

Some industries, however, find that their coal supply is now running far ahead of their consumption under the reduced output incident to the close of the war. The fact that many industrial coal piles will last for weeks longer than was expected as a result of the coming of peace is also sharply reflected in orders for fuel.

Shipment of the less desirable coals is rapidly dwindling in the face of the release of better coals to the general market. Many representatives of coal mines are arriving here with offers of coal, but an encouraging feature is that none is talking of cutting the Government maximum.

As soon as the Government can release ship bottoms for the export trade and make some readjustment for the protection of freight rates in competition with British shipping handling Welsh coals, a giant coal export is expected. Baltimore in 1915 reached a total of more than 2,000,000 tons on export bituminous, anthracite and coke combined, and if this can be resumed or bettered here and elsewhere excess production in this country can be readily handled.

Anthracite—The first real winter weather has come to this section. Weeks of mild temperature vastly cut consumption here. The end of the war has brought to an end the "fancy" salaries of many war workers. All of this is having an effect on the situation here, and the expected new demands for coal have not developed. With coal prices so high many are "mothering" fires to save coal and are hoping for an early spring to enable them to pull through on the original two-thirds delivered, or just being delivered, by their coal men. Not a few are now refusing to receive the remaining one-third of their orders. There is enough business still undelivered on the books of the two-thirds of absolutely needed coal, however, to keep the coal men busy for a time. All incoming fuel, and it is now liberal in supply, is rapidly absorbed. Egg and pea coal at times is probably a little too liberal in supply, but stove is short in spots and nut hard to get. Buckwheat, which the public here never took kindly to as a domestic substitute for other sizes, even for mixing, is a drug on the market.

Lake Markets

PITTSBURGH

Production still below normal. Steam coal fairly steady with gas coal strong.

Coal production in the Pittsburgh district last week was well below normal and not much heavier than in Christmas week. There is now observable a tendency on the part of mine managements to allow their men to celebrate holidays as freely as they like, and in several cases mines have been closed entirely, partly as a contribution to the general market situation.

All observers agree that the Pittsburgh district is faring much better than other coal districts in connection with the general decrease in demand for coal and the tendency on the part of consumers to reduce their stocks. The weakness in steam coal is not pronounced, while gas coal is decidedly strong, rather than weak. Except for decidedly off grades, concessions on steam coal are usually confined to the allowance of brokerages of 10 or 15c. to dealers, who charge the consumer or retail dealer the full Government limit, but of course without the brokerage that the regulations permit the dealer to ask. In the case of gas coal brokerages are not usually allowed by the producer, and dealers have been able to effect sales without much difficulty at Government price plus brokerage.

There is an insistent demand for gas coal, and mine-run usually has to be taken, as the ⅜-in. being produced is absorbed by contracts, as is the slack resulting. The mine-run being sold in spot lots is chiefly from wagon mines. Some of the wagon mines producing steam coal have closed, but the gas coal wagon mines are still operating. As a rule they now secure only the Government limit, without the extra allowed for trucking. Government limits remain at $2.10 for slack, $2.35 for mine-run and $2.60 for screened, per net ton at mine, Pittsburgh district, and the market may be quoted at Government limits to consumers for steam coal and at the Government limits up to the limit plus brokerage in the case of gas coal.

BUFFALO

Bituminous very quiet. No prospect of early improvement. Jobbers still wait for a stir. Plenty of anthracite. Light consumption.

Bituminous—The demand is still slack. Consumers no longer fear a shortage and are using up their surplus. Most of them have a heavy supply. They see in the big production a prospect of lower prices, but are not generally willing to buy on the offer of reduction. As a rule the sellers are not cutting the price, but it looks as if they would do so before long. New mines are sending representatives to this market, and they do not expect to do business on full prices.

Jobbers complain about as freely as they did when the operators had no coal to turn over to them. Now it is the consumer who has no use for them. Still they are much more hopeful than they were. When

the surplus in consumers' hands begins to disappear they will get business again. The railroads are buying pretty generally, but they refuse to pay any profit to the jobbers. This leaves the jobbers pretty nearly out, but this condition is not likely to last, for the consumers must have more coal soon.

Anthracite—The supply increases at such a rate that all uneasiness has disappeared. The prospect is that there will be plenty of hard coal in a few days, so that a retailer can go to a city trestle anywhere and get what he wants. This is a state of things that has not occurred in two or three years, and is quite different from what was feared even a month ago. The shortage has been overcome for the most part by an increase of supply. It is true that the consumption has been extremely light all the season so far, but there has also been a great shortage of natural gas, which has in part offset the extra amount of coal. It is not now believed that any amount of cold weather will be able to cause a further shortage this winter.

And now comes up the question of anthracite surplus. Already the independent shippers are finding it hard to sell their output, especially if it is not known to be of the very best quality. Few consumers will order it unless they need it urgently or are acquainted with the quality. It is predicted, even by the jobbers who handle independent anthracite, that it will go at a discount before long, mainly because the regular prices are so high.

CLEVELAND

Signs that some steam coal will be bought in January are becoming brighter. The movement is not expected to be large, but undoubtedly will prove quite sustaining in the present weak market. Holiday celebrations have cut heavily into production, a thing which is not now causing operators here any concern.

Bituminous—One large user of steam coal in the greater Cleveland district has directed the interest with which it has been doing its coal business to resume shipments, at the full Government price, on Jan. 10. Other industrial consumers are also showing activity, and many operators look forward to a brisk—in a comparative sense, of course—market by the latter part of the month. Stock piles have been well depleted by those interests that have not been taking any coal since the middle of November or thereabouts, and it is expected they will be forced into the market shortly.

For this reason, mainly, operators declare they are holding firm to the Government price schedule. Actuating this stand to a degree is the belief of some operators that quite a few steam-coal users quit buying soon after the armistice was signed to try to weaken the market. While some standard No. 8 coal may be bought here and there slightly under maximum prices, it doubtless is the case that an overwhelming percentage of standard coal has not been shaded. Stripping coal has been pretty well swept out of the market by the oversupply of standard No. 8 coal, and continued offers at 50 to 70c. off have not proved successful stimulents.

Cold weather has finally set in, and domestic demand has responded to this change. Retailers' business, however, still is only a fraction of normal, and a revival in earnest is no longer expected. Receipts both for industrial and commercial use have fallen in proportion, for holiday celebrations at the mines were severely felt. In most cases they were of two days' duration, but with the market as it now is, operators did not object.

Anthracite — Receipts are increasing somewhat, dealers formerly satisfied with five to six cars a week now being able to get eight and ten. Demand has improved slightly because of the coming of winter weather, but not much more than present receipts could be disposed of because of the large domestic stocks of bituminous.

DETROIT

Various conditions, prominent among which is an over-supply of stock on hand, contribute in creating an inactive market for bituminous coal in Detroit.

Bituminous—Business of jobbers and wholesalers in the Detroit market is pronounced far less satisfactory than is usual at this season of the year. Their efforts to interest buyers of steam coal and retail dealers in the product of West Virginia and Ohio mines, which has again become available, is disclosing that quite a number of the buyers believe they are already holding more coal than they should.

Other causes tending to diminish the volume of buying in the local market in the closing week of the year include the general reduction of industrial activity that comes with the period for taking an annual inventory. To this may be added the cutting down of operations following the cancellations of numerous Government contracts for supplies for war purposes; the holding back of settlements on such contracts and the difficulties some manufacturers are meeting in trying to get materials they need to replace their plants on a peace basis of operation.

The stocks that some of the retailers and steam plants seem to find burdensome are said to include quite an amount of the coal from Indiana and Illinois, which was sent into the local market in large amount during the late summer and was bought because of the uncertainty that then seemed to obscure the outlook as regards ability of the buyers to get more desirable stock. The comparatively warm weather through November and December prevented the materializing of the expected retail demand.

Anthracite—Though not very much anthracite is coming into Detroit, the weather so far has been favorable to light consumption and dealers have not been subjected to any considerable degree of urgent demand from domestic consumers. The pressure for anthracite is also being relieved to a noticeable extent by a more plentiful supply of coke and by the fact that household consumers are now permitted to use coke to the full limit of their fuel requirements, although, in the case of anthracite, they are still required to provide a supply of bituminous equal to one-half of their fuel needs. The fuel administration has announced that the maximum price for coke delivery anywhere in Michigan will be $10.75 a ton.

COLUMBUS

Coal trade in Ohio still rather quiet, but there are signs of revival of interest. Domestic trade is stimulated by colder weather. The steam business is dull, as consumers generally are overstocked. Prices are fairly well maintained.

Because of the fact that most steam users are heavily overstocked with fuel, there is little steam trade in Ohio territory. Consumers are loath to buy under present conditions, and they are following the policy of using up their reserve stocks. Railroads are not using as large a tonnage as formerly, and in addition there is a movement on the part of the purchasing department to hold off in the hopes of beating down the price. Consequently, current business in steam grades is not large. Quite a few of the users who cancelled orders several weeks ago are asking that they be reinstated, showing a better feeling in steam circles. But on the whole the steam trade is quiet and not a great deal is expected for some time. Michigan is fairly well stocked up, and the same is true of the manufacturing localities in northern Ohio.

The domestic trade is slightly more active, due to lower temperatures which have prevailed. Retailers have been fairly busy in the past few days making deliveries, but the activity in domestic grades is not long enough to have it reflected to any great extent on the operating end. Retail stocks are fairly large, and consequently dealers are inclined to use up reserves. There is a fairly good demand for Pocahontas and other fancy grades. Prices in the retail trade are generally well maintained, but there is some shading on the part of certain dealers. This is not sufficient to demoralize the market, however. Retailers look for a better demand when the expected cold wave arrives. The season so far has been unusually open.

CINCINNATI

Colder weather has stimulated consumption somewhat, but supply is much in excess of the demand and consumers' stocks seem ample for the rest of the season.

Business among the coal trade in this section remains almost wholly under the influence of the heavy stocks of fuel which were stored by both industrial and domestic consumers in preparation for the current season, coupled with the comparatively small consumption, especially of steam fuel.

The quiet of the reconstruction period is prevailing with the manufacturers, many of whom have greatly curtailed production as a result of the cancellation of war orders, while others have closed down completely, for the purpose of changing their plants back from a war to a peace basis. The net result is that industrial activity, aside from the normal year-end and holiday quiet, is less than at any time in the past two or three years. Moreover, the remarkably mild weather so far experienced, broken as it was at Christmas by a light snow, and by colder weather just now, has made the consumption of fuel for heating purposes much less than normal, and stocks laid in for the winter have been reduced very little.

Present indications are that unless the remainder of January and the following winter months bring a sustained period of cold weather, consumers in all classes will carry over considerable stocks of fuel. However, indications are also favorable to cold weather, at least during the current month, to help consume the stocks on hand and thus prepare the way for a good spring season. The resumption of industrial activity in many lines is also looked for, with a corresponding increase in the use of fuel for steam purposes.

LOUISVILLE

Drop in temperature improves demand from small steam plants. Domestic demand quiet. Industrial demand fair only. Market slightly firmer.

Since Jan. 1 cold weather has about doubled the consumption of small steam plants in office buildings, central stations, etc., and has made things slightly more active for the retailer. However, domestic demand is not increasing materially, as consumers were well stocked and for the early fall and winter used coal considerably under expected requirements. The general steam demand is dull, due to the fact that industrial consumers are not especially busy. Coal is generally plentiful, and yards and bins are well stocked. Some river coal is now coming in and much larger shipments are expected within a few days.

Things at the mines show little improvement. Most of the mines are getting back into the running again after being down for the holidays, but some are not turning a wheel until a larger volume of business is booked. In several sections the mines have considerable coal in box cars and are trying to find a market for it. However, there is little unsold coal in transit.

Except for the small production of the past few weeks and the holiday shutdown, it is believed that the market would have broken sharply. However, reduced production has strengthened the market all around. Retailers are holding prices firmly. There is some coal being offered at mines at prices slightly under Government maximum quotations. However, this is mainly in connection with small mines and wagon mines, although a few producers are absorbing brokerage.

There has been a better demand for railroad coal during the past month than for some time past. Several of the Eastern and Southern roads have been buying freely. However, several of these are now loaded up, and by Jan. 15 it is claimed that the railroads will be fully stocked and this market cut off.

Excellent boating stages in the Ohio River are expected to result in considerable coal coming South. One local concern received ten barges a few days ago, which is the best shipment of river coal received in many months. More river coal would be moving except for the fact that river coal companies are still heavily stocked on rail coal. However, with a high river stage, free of ice, indications are that big operators will carry coal South on the rise, and await a market for it.

BIRMINGHAM

Domestic coal unusually scarce and demand heavy. Inquiries for steam coal good, but not specially insistent. Production took a big slump around the holidays.

Inquiries for domestic coal are especially strong at this time, both locally and from points throughout this zone, reports indicating a shortage at most all the chief consuming centers. Local dealers have little coal on hand and are unable to secure tonnage requisite to their requirements.

While steam-coal users were unable to stock much coal to carry them over the holidays in view of the restricted production which has been the order for the last month or six weeks, inquiries are not as strong as might have been expected. However, ample business is being booked to absorb fully the tonnage now being produced. Shortage of stocks is more manifest with the railroads than any other class of consumers, receipts and consumption running on a close parity with some of the lines.

Coke

CONNELLSVILLE

Coke scarcity increased. Operators show some indifference in matter of production. Furnaces indisposed to pay advances in event of Government control being relinquished. Market lower for screenings.

Coke has become extremely scarce, blast furnaces having felt for the past ten days the effect of the sharp decrease in Connellsville coke production and in shipments of byproduct coal that occurred during Christmas week. Several blast furnaces have been forced to bank, while many others are operating at reduced rates in hope of avoiding banking. Last week's production was not much heavier than that in Christmas week.

Many coke operators seem disposed to allow or even encourage their men to celebrate holidays whether on the calendar or not, and the Greek church holidays occur this week on account of the difference in the calendar. Evidently it is felt that reduced output of coke will prove an advantage to coke producers in the long run.

There are no prospects of an early removal of Government price restrictions, and while predictions have been made that if the control were removed when coke is as scarce as at present the market price would advance sharply, second thought indicates that the blast furnaces would hardly bid against each other for coke as they have sometimes done in the past, but would rather be disposed to bank.

Last week the blast furnaces generally reduced their pig iron prices $3 a ton, tardily following the program of price readjustment that had been mapped out by the American Iron and Steel Institute Committee for presentation to the War Industries Board Dec. 11. While the board did not receive the recommendations, they were given publicity and have had some standing. Having reduced their product $3 a ton the blast furnaces would hardly be disposed to pay any fancy prices for coke in the open market. The market is quotable at Government limits on furnace and foundry: Furnace, $6; foundry, 72-hour selected, $7, per net ton at oven. Crushed, over ¾-in., is nominally held at the Government limit of $7.30, but there is little being done. Clean screenings from old dumps, over ½-in., on which the Government limit is $5.50, no longer bring that price, and $5.25 is not easily obtained, as dealers who stocked up in anticipation of good demand for this material for domestic use have found their stocks move very slowly.

Buffalo—The situation grows easier, especially as the coal supply is no longer short. Besides, the output of pig iron has succeeded the demand of late, and the furnaces are not crowded. A Buffalo furnace owner is reported to have said within the past week that he had shut down one furnace and would follow with more if the iron sales did not pick up, for he was not going to stock up on this outlook. He was sure that prices would be easier soon. All this reduces the consumption of coke, so that the demand is quite moderate. Off grades are not selling well, but best quality is fairly active. Fuel coke is quiet, on account of the slackness of the coal trade.

Middle Western

GENERAL REVIEW

Brief storm followed by cold spell did not help coal situation as much as was expected. Tonnage decreasing. Coal carrying equipments not in demand at mines. Operators believe export of coal would help.

The Middle West recently received its first touch of winter. The storm that swept over the territory lasted two days, and was serious enough to hamper traffic to a small extent. This was followed by cold weather, which was of short duration, the temperature having climbed upward steadily for the last few days. The weather man predicts a storm on its way from the Rocky Mountains in the Northwest, which will affect our territory, including the Ohio Valley. Last week's blizzard proved one thing to the satisfaction of the coal man, and that is the present situation is beyond any substantial help from ordinarily favorable weather conditions. There was scarcely any noticeable difference in the market after the storm. Of course, it cannot be denied that the prolonged cold weather will have a beneficial effect on the market, but this effect will not be as great as previously hoped for by the coal operator.

A sharp decrease in tonnage continues, both for Illinois and Indiana, and in our opinion no improvement is to be looked for until perhaps the middle of February, or later. The coal-consuming public are seizing on the present weak market to dispose of their stored coal, and developments have shown that much more coal has been held in reserve than heretofore suspected, with the result that the public will not come into the market in any great force until some six to ten weeks hence.

The operators are facing the present condition with an admirable spirit. They have seen that very little, if anything, is to be gained by price cutting, and they have made up their minds to let their mines remain idle, rather than operate on a basis below the present Government price, and consequently at a loss.

It is a very unusual thing, at this time of the year, to note long strings of empty coal-carrying equipment in the various railroad yards, but the fact of the matter is that the yards in Chicago are practically cluttered up with strings of empty coal cars, which have not been sent down to the operating fields because there is no demand for them.

One of the problems that the Illinois and Indiana operators are engaged in solving at this time is the question of whether or not all coals will continue to be sold on the basis of Government price. It is generally known that there are a great many qualities of coal coming from both of the states mentioned, and an operator cannot expect the public to pay the same price for an inferior product that they would pay for the best coal that the state has to offer. The operators will have to adjust this question themselves, and, of course, the poorer grade products will have to be marked down from the Government price. In our opinion, this matter is a question for the coal operators' associations in the different producing districts of Illinois and Indiana, and is a question that should be handled and settled at as early a date as possible, in order that the market may the more readily adjust itself to new conditions.

The Western operators are looking at the situation in the Eastern coal fields with a great deal of interest, as they feel that if any immediate relief is to come, it will be through the East. The feeling is that there is a great demand for coal in Europe and South America. In fact, the press contains numerous mentions of the fact that coal is selling on those two continents at from $60 to $120 per ton. The coal operators feel that if the proper authorities took the matter in hand, and exported coal to these countries, that the situation in the United States would be relieved to some extent. Of course, this would take time, but the sooner it is undertaken and got under way the better. The general opinion in the West is that if any relief is to be looked for, it will have to come from our exporting activities.

If a substantial tonnage was exported it would keep Eastern coal out of Indiana and Michigan, and thus allow the Western coal to resume the place it had in Indiana and Michigan before the signing of the armistice.

CHICAGO

Domestic consumers seem to be stocked with coal. Large operation works only two days a week. Railroad buying a little more active.

There is practically no demand for domestic coal in the city. The recent storm, if it did nothing else, brought to light the fact that the average householder has a good supply of coal in his cellar, and is not a bit nervous about the prospects of a serious spell of cold weather. A look into the average dealer's yard showed no signs of extra activity; in fact, business was carried on just as sluggishly during and after the storm as it was before.

Some of the higher grade products of Franklin County suffered on account of this lack of market in Chicago. In fact, we understand that one of the biggest mines in the field, with a production of over 4000 tons per day, has only run two days in the last two weeks. This fact will give a general idea of the situation in Chicago.

There is some buying of steam coal, but not enough to make itself felt in any degree. The railroads are coming into the market a little more generally than they have heretofore, but are not making any purchases, merely giving instructions to renew shipments on orders previously placed.

MILWAUKEE

Order reducing the price of byproduct coke is rescinded. Mild weather slows up consumption and makes the outward movement slow. Solicitation renewed.

The reduction in the price of byproduct coke to $11.50, announced by the Fuel Administration last week, did not stand long, and this class of fuel is now retailing at $12.25, except pea size, which is listed at $10.25. There is no extra charge for delivery into bins, however. The reversal of the order reducing coke was brought about by the producers, who brought influence and argument to bear upon the administration.

A continuation of mild weather has a depressing effect upon the trade, and it is reasonably certain that a sudden withdrawal of price regulation would precipitate a slump in soft coal, as holders of eastern bituminous are meeting with increasing competition from western producers. Last year at this time there were no agents on the road, and orders were accepted subject to regulation as to delivery and price. Now dock companies are soliciting business.

It is an assured fact that there will be no coal famine. The last run of hard coal by lake helped out wonderfully, and under present weather conditions and with supplies coming daily by rail, there will be enough hard coal for those who are unable to burn bituminous. The rule allowing two-thirds of last year's supply to consumers with magazine heaters or hot-air furnaces, and one-third to those with steam or hot-water plants, is being adhered to.

There is no trouble in securing cars for rail shipments this year, and absence of deep snow makes rail hauling steady and more reliable.

ST. LOUIS

A slow and heavy market with a better tone at the end of the week and indications for better conditions. Steam demand is easy but domestic demand shows improvement. Surplus of all grades and sizes of coal. Transportation fairly good.

Expressions on the local situation are optimistic. The present winter has been the mildest since 1877. Up to the first of January there was not what might be called one cold day in the season. On the first of the year the weather got cold and at the end of the week it was below zero.

There has been a good supply of coal in storage, but this has affected the market only to a small extent. Here and there, however, are little indications of what is to be expected if seasonable weather continues. The steam demand everywhere still continues light. There is a little buying, but the storage piles are receiving the most attention. Some of these piles have been on fire and they are being gradually cleaned out, the consumer purchasing just enough coal on the open market to mix with the storage coal to help the general situation. The domestic demand with the first of the year picked up, and retailers everywhere are optimistic as regards the future. The demand, however, has not been sufficient to create any great change in the wholesale prices. Standard coal is still heavy, and many mines are idle on account of their failure to move the screenings. The railroad buying has been light but it is expected that the new year will bring in considerable railroad business. This will help the screening situation.

The country demand for Standard is easy. Cars are plentiful and there are no labor troubles nor anything out of the ordinary other than lack of business to keep the mines going. The domestic demand for Standard is not good, the call being for the higher grades.

The Mt. Olive situation continues to be the most satisfactory. There are plenty of cars, mines are working on rather good time, and although there is some coal unbilled, it is not in sufficient quantities to cause any worry. These prices are holding up to practically the Government maximum, whereas the Standard 2-in. lump is down to as low as $1.50 to $1.75, screenings as low as $1.30 to $1.50, mine-run $1.65 to $1.70, and 6-in. lump from $1.75 to $2. The domestic demand is fairly good for the Mt. Olive grade, although steam in St. Louis proper does not call for much of this coal. The steam demand is farther north, and in the country.

Conditions in the Carterville field show considerable improvement. Cars are not as plentiful as they might be, but there is an oversupply of them for some mines that are idle on account of no business. This affects the Williamson County field more than it does Franklin County.

There is plentiful supply of this coal coming in right now, but nothing to indicate that it will continue to come in if extreme weather grips the northern territory for any length of time. Then this coal would be diverted north. There is, however, a fairly good supply of this coal in storage by the retailers, and such steam users as have been able to get it are fairly well supplied. This coal practically holds to the Government maximum, although screenings are in some quarters long and in other sections are short.

For the first time in many months some anthracite buckwheat was offered on the St. Louis market but found no takers. There is a little Arkansas anthracite and smokeless coal coming in, but not in any great quantities. In a general way the market shows some improvement, and the coming week will probably develop better prices on Standard coals, with also a possibility of higher prices for retail, which are now below the figure fixed by the St. Louis Fuel Committee.

COAL AGE

Volume 15 New York, January 16, 1919 Number 3

Coal-Mining Results in the United States in 1918 and the Present Outlook

The Production of Coal in 1918 was the Greatest in History

The total output was	689,652,110 short tons
An increase of	38,526,110 short tons
Or nearly 6 per cent. over 1917.	
Anthracite production was	99,514,334 short tons
Or 179,334 tons more than in 1917.	
Bituminous production was	590,137,776 short tons
Or 38,346,776 tons more than in 1917.	
Coke output was	56,670,000 short tons
Or 1,603,000 tons more than in 1917.	

Byproduct coke increased nearly 4,000,000 tons while beehive coke decreased upward of 3,000,000 tons.

THE year that has just passed proved conclusively that in time of crisis, the ability of American mines to produce fuel is greater than the ability of our industries to consume it. If the war had continued through the year, the production of coal would undoubtedly have been in excess of 700,000,000 tons. Following the signing of the armistice in November the coal output decreased materially, the production in December reaching the lowest total of the year.

The country may look with satisfaction upon the record that was made in the emergency that existed. The stocks of coal in November were nearly three times as great as those that were in yards one year ago. Since bituminous coal is a product that cannot be satisfactorily stored for long periods, the natural outcome of the situation in recent weeks has been for the mines in most districts to curtail production. Only in this way can the large stocks of coal on hand in industrial yards be used up and normal conditions in the coal trade be resumed.

A backward look at the history of coal mining shows that only three times did it require an interval of two years for production to come back and exceed the last peak that was established. It is likely that the coal output in 1919 will be less than it was last year, for during the early months of this year the Nation will be going through a serious time of reconstruction. More than 10,000,000 tons of coal have already been released by the cancellation of war work in powder, airplane and small arms plants. The navy consumption will be 4,000,000 tons less this year. The railroads have effected plans that should save upward of 8,000,000 tons during 1919. Conservation measures that were forced on industries by the needs of the war will bear fruit during the coming months and bring about other material savings.

On the other hand, there is very little cessation of work in most of our great steel plants, and many businesses that were restricted during the last year are again resuming operations in a most hopeful fashion. One of the promising spots in the situation is the probability of greatly increased exports. For the first time in a generation America possesses a merchant marine. France is on the verge of a coal famine. The mines of both Belgium and France cannot be counted upon to relieve the situation, due to the fact that for the present there is absolutely no place for miners to live in the regions devastated by Germany. In most localities where mines existed there is not a single house to shelter anyone within ten or twenty miles of these collieries. Italy is also begging for American coal. These important foreign markets are ready for the American producer if only the Nation will immediately effect a program that will provide sufficient ships and establish reasonable rates. America should send 30,000,000 or 40,000,000 tons of coal to foreign markets in 1919 instead of the measly shipments of 10,000,000 or 15,000,000 tons heretofore exported.

Due to the war, Europe is minus the labor of 20,000,000 men killed or disabled. America today is not only the richest nation on earth but the greatest storehouse for raw materials that exists anywhere. Labor and capital understand each other better here than in any other country. This will result in a degree of coöperation that should introduce an era of unexampled prosperity. Fuel is the product necessary to turn the wheels. Before the last snow has fallen this winter, industries will be humming and America will have started on its career of greater internationalism in all its industries. The few weeks of hesitation furnish the coal operators with a much needed opportunity to rejuvenate and reëquip their plants. In 1919 competition will again be in force, and the best designed and best equipped collieries will enjoy the greatest success.

Activities in Different Coal-Producing States During 1918

THE year just passed has been a strenuous one. It was the first year in the history of the industry when Government control was exercised throughout the entire twelve months. As a general rule, however, operators who regarded Federal regulation with fear and trembling approach the return to normal, that is competitive, conditions with the same foreboding. Throughout the entire land a shortage of labor has been experienced. Enlistments and draftings into the army and navy have had their effect in reducing the operating forces of the mines. While no region was exempt, miners from the eastern and western fields were powerfully attracted by the high wages and steady work offered by the munition plants and shipyards. The coal digger, proverbially nomadic in his habits, promptly "pulled up stakes" and sought employment in more promising fields whenever his earnings from fuel production became lower than he thought they should be. Strenuous efforts were exerted by many of the coal companies in an effort to keep their working forces somewhere near normal and adequate. Car shortage, which has been the great handicap to maximum production in past years, was less felt in 1918 than was anticipated. Because of embargoes and priorities, however, shortages of mining supplies developed in some places. As a rule these were not in the main serious, and they exerted only a minor depressing effect upon production. As to the future, much is uncertain and few in the coal industry are willing to hazard a prediction. It is but natural that the problems of the immediate future, those that affect the destinies of the nation and in fact the entire race, should also possess a powerful influence over the third industry of the land. Most leaders of those engaged in coal production are agreed, however, that the immediate future is bright. There appears to be no reason why both output and consumption can not—within reasonable limits—be maintained. The following reports, written especially for *Coal Age*, in most cases by the chief mine inspectors of the various states, set forth in detail the results of the past year's effort. It is regrettable that the fiscal years of some states do not coincide with the calendar year. This is confusing, and a change to the calendar year would be beneficial to all concerned.

Alabama

By C. H. Nesbitt
Chief Mine Inspector, Birmingham, Ala.

THE coal production of Alabama for the year 1918, from present estimates, will total 19,000,000 tons. This is a decrease of 1,500,000 short tons as compared with 1917, notwithstanding that many new mines were opened and all operations ran with fair regularity throughout the entire year. To a certain extent the decrease is attributable to the influenza epidemic that prevailed the greater part of the last three months of the year; also to the fact that the mining industry of Alabama, like all other industries throughout the country, has been handicapped by a lack of labor. The state has been drawn upon heavily for men for military needs.

C. H. Nesbitt

The mining business in this state has been exceptionally good, and all grades and qualities of coal have not been equal to the demands for coking, steam and domestic purposes. Many improvements have been made during the year at different plants, notwithstanding the increased cost of material and the labor shortage. The fatalities recorded thus far have been those of a regular nature, and equal the record of 1917.

Proposed Government control of the transportation facilities on the Warrior River holds a bright prospect for the mining business in that section of the field. This will furnish a long desired outlet for Alabama coal as it is anticipated that shipment by river will enable a cheaper rate to Gulf ports.

The prospects for a good trade for 1919 are promising. This, however, depends upon industrial activities in other lines.

Alaska

By Sumner E. Smith
Alaska Engineering Commission, Eska, Alaska

PROBABLY about 75,000 tons of coal were mined in Alaska during the calendar year 1918. Of this amount the Alaskan Engineering Commission, operating leasing units Nos. 7 and 12 in the Matanuska Field, produced about 60,000 tons. Henry Baxter, manager of the Matanuska Coal Co., produced about 3000 tons early in the spring.

The Chickaloon Coal Co., of which Walter A. Gompertz is manager, ran several thousand feet of tunnels and has now started operations with diamond drills on its lease covering units Nos. 10 and 11 in the Matanuska Field. The Little Susitna Coal Co., operating near the main line of the Government R.R., not far from the Little Susitna River, produced about 2000 tons of coal; and the Cache Creek Dredging Co., operating a dredge on Cache Creek, mined about 5000 tons, which was used to generate electric power for the dredge.

Maitland & McNally, of Anchorage, Alaska, are operating what is known as the Wharf Mine at Bluff Point on Cook Inlet, producing coal for the cannery trade. They probably sold some 5000 tons during the year.

It is reported that the Alaska Coal and Petroleum Co., of Katalla, has mined about 1000 tons from its property on Canyon Creek in the Bering River Field. Operations have also been started by a company promoted by Falcon Joslyn and George Hazlett on a lease coving a portion of what was the old "English Company" ground at Katalla.

Several thousand tons of coal were mined in the Nenana Field for use in construction work on the Government

R.R. Most of this was produced from free-use 10-acre leases by small operators. The balance of the total tonnage was made up entirely from the production from free-use 10-acre permits scattered throughout the territory from Chicken Creek on the Upper Yukon to Candle on the Seward Peninsula. All of the foregoing figures of production are in short tons.

Arkansas

By Claude Speegle
State Mine Inspector, Fort Smith, Ark.

TO GIVE a review covering all the developments of the coal-mining industry of this state during 1918 is impossible. The coal region of Arkansas covers about 2000 square miles and comprises the six counties of Sebastian, Scott, Franklin, Johnson, Logan and Pope. The production of coal in each of these six counties is of commercial importance, but the counties producing the largest amount of coal are Sebastian, Johnson and Franklin. Sebastian County alone produces more than one-half the output of the entire state.

The approximate amount of capital invested in the coal-mining industry is $2,896,600. The production for the fiscal year ending June 30, 1918, was 2,373,687 short tons. The market value of this coal was approximately $7,777,080.

To produce this amount of coal 4425 miners and company men and 394 mules were worked in the mines. The miners used 99,028 kegs of black powder, at a cost to them of $198,056. The mines hoisted coal during 15,725 mine days.

Fatal and Nonfatal Accidents

Fourteen fatal and 150 nonfatal accidents occurred during this period. There were 169,549.14 tons of coal produced for each life lost and 15,824.87 tons for each nonfatal accident.

There were 378 office men and mine officials employed, making a grand total of 4803 persons actively engaged in and depending upon the mining industry. The total number of coal mines in the state is 155.

Washington and Crawford counties produce a small amount of coal, but owing to the thinness of the bed this fuel is only mined for local use. Ouachita County has a bed of lignite coal 15 miles in length and 7 miles wide, with coal 5 to 6 ft. in thickness. However, this field has never been developed, and its coal is only mined for local consumption. A great number of small mines and five large ones have been opened up in this state within the last year.

The amount of coal produced in Arkansas for the last six months of 1918 was approximately 1,257,434 short tons. This is as nearly correct as can be given at this time. The exact figures are available for five months, but the output for the month of December had to be estimated.

Colorado

By A. R. Tibbits
State Mine Inspector's Office, Denver, Colo.

DURING the year 1918 the coal industry of Colorado was confronted with many changes, but no effort was made tending toward stabilizing conditions. Early in the year there were insistent demands for increased production. Coal consumers both in this and the surrounding states were alarmed by reports of an impending coal famine, and there were strong indications that such a condition might be forthcoming.

In 1917 Colorado produced 12,515,305 tons, and in the beginning of 1918 the demand was such that it appeared we should face a shortage of approximately a million and a half tons. In order to avoid this danger every effort was made to speed up production. However, the industry was hampered by the issue of rules and regulations by the Federal Fuel Administration, often conflicting in their terms. The labor situation became serious, many of our best miners enlisted, others were drafted, and it should be remembered that Colorado for many months had been decidedly short of genuinely competent miners. Therefore, the operators were left to face the increasing demand with vastly reduced competent help.

James Dalrymple
State Mine Inspector, Colorado

The car situation on the other hand showed some improvement over previous periods. During March, April, May and June quite a number of mines at which small beds are being worked were compelled to close down because of the inability to operate at anything approaching a reasonable profit at the selling prices established by the Federal Fuel Administration. Later on, this matter was taken up with the authorities and partially adjusted, but this adjustment took considerable time, which resulted in a serious reduction in the tonnage of the properties involved.

Colorado consumes nearly all of her output, in 1917 only 2,634,458 tons were shipped out of the state, but when the system of zoning was put into effect by the Federal authorities, there was created a greater market outside of the state for Colorado to supply. A great drive for increased production was made, and all the mines worked full time. Early in the summer all the individual consumers who could pay for a winter's supply of fuel, and had the storage room, filled their bins. Also the yards of the local dealers and railroads were stacked up to the limit with coal, to meet demands for some time to come. In fact there is more coal stored in Colorado and by the jobbers in the adjoining states than in any previous year.

On Nov. 1 the production amounted to 10,812,548 tons, an increase of 516,379 tons compared with the same period of 1917, and about one-third of the expected increase. However, instead of a coal famine, there came a slump, which the sudden cessation of the war with the consequent cancelling of war orders and closing down of munition plants made more acute, with no prospect of an early revival of the business. The mines have slowed down, in some localities working only half-time, and many of the small operations have closed down altogether for lack of orders for their product. The drop in the production brought the increase of 516,379 tons of the first ten months down to 197,932 tons increase by the end of December.

With wages and the cost of production high, the retail selling prices were correspondingly high; but the wholesale prices per ton at the mines were slightly lower than in 1917.

The western slope, where a good grade of domestic coal is mined, was seriously affected by the closing down of the Colorado Midland R.R., leaving a number of small towns without direct railroad connections. This situation affected a number of mines in Garfield, Gunnison and Mesa counties.

In 1917 Routt County produced 1,057,685 tons and in 1918, as seen in the table, the production shows a decrease solely due to poor railroad facilities. In the winter and spring the heavy snowfalls almost completely blocked transportation, but an efficient railroad service could have overcome this to some extent. There is a steady demand for the coal of this district in Kansas and Nebraska because of its high thermal content and its fine storing qualities, also because it is not subject to spontaneous combustion. It can be shipped any distance and stored for a long time without impairing its value. In November 1000 cars of this coal was ordered, but could not be delivered, because of a lack of cars and the existence of snow blockades.

The only drawback to the free development of the mines in this district is the lack of an efficient railway system. However, the Denver & Salt Lake R.R. officials are making strenuous efforts to improve the system, and have built adequate snow sheds, installed new equipment and relaid the tracks where necessary. It is now the hope of all concerned that in the future transportation of cars will improve.

In the northern field where the lignite or sub-bituminous coal is mined, the question of slack is a serious one. This variety of coal makes about 49 per cent. of slack. The cost of production is as high as in the other coal-producing localities, but the product sells at a lower rate. This slack, in competition with the slack of other coals, is not in demand both on account of its slightly lower heating qualities and the fact that it will not stand storing. Unless quickly sold and used, it has to be dumped and represents money lost.

Many solutions to this problem have been considered. The making of briquets is not practicable because no cheap binder is available. The great sugar plants that operate in this field and can use this low grade fuel to advantage solved the problem to some extent by storing this slack in concrete pits covered with water, removing it as needed. One hundred and ten

PRODUCTION OF COLORADO BY COUNTIES FOR 1918, ALSO INCREASE OR DECREASE COMPARED WITH 1917

Number of days worked per mine			196
Number of mines in operation			230

thousand tons of lignite were thus stored in the past year. This method of storing the lignite slack in the summer season eliminates any shortage of coal that may be caused by the increased demand for cars to move farm products in the fall and winter and makes a steady market for a product that is difficult to dispose of.

Most of the coal mined in Las Animas County is made into coke and is consumed at various plants in Colorado. As a domestic fuel none can be rated higher than that of Huerfano and Fremont counties, which is in great demand because of its splendid heating qualities and cleanliness.

There were no labor troubles other than a scarcity of experienced miners to add to the difficulty of the coal situation. In the northern field there was a moderate demand for the soft coal, resulting in the mines working only half time and cutting down the wages of the men. This prompted many of them to leave the state to seek better paid employment.

There were substantial improvements made at many of the mines in spite of the fact that the cost was extraordinarily high. The welfare of the employees received attention, and in many of the coal camps the living conditions were considerably improved. The rate of fatalities was about 4.7 per thousand men employed. While this is a high death rate, yet considering the preponderance of inexperienced and foreign-born men working at the mines it shows that safeguards to protect life were enforced to an appreciable extent.

It is difficult to say what the effect will be on the industry when the various restrictions placed upon it by the war are lifted. With an overstocked market, selling prices are bound to drop. However, in common with other coal producing states, Colorado will solve the new problems and work out matters satisfactorily.

Idaho

By Robert N. Bell

Boise, Idaho

THE Horseshoe Creek coal field of Teton County, Idaho, is the only portion in the whole State of Idaho that has so far developed a commercial coal mine. It embraces a portion of the famous coal-bearing formations of Wyoming, which extend for a short distance over the border into Idaho. The Horseshoe coal field is situated on the eastern slope of the Big Hole Mountains, 12 miles due west of Driggs, in Teton County, southeastern Idaho. Driggs is an agricultural center and the county seat of Teton County, with a population of 1000 and

Robert N. Bell

the end of Teton Valley branch of the Oregon Short Line Ry. The elevation is 6000 ft. above sea level. The Big Hole Mountains comprise an L-shaped spur of the Tetons, one of the major ranges of the Rocky Mountain system. The "Grand Tetons," as they are called, have some of the steepest and most spectacular, as well as the highest peaks, in the United States. They are plainly visible from the coal property, towering to an elevation of nearly 14,000 feet.

These coal deposits have been operated since their discovery in a desultory fashion by the original claim owners and were locally known as the Brown Bear, Boise, Horseshoe and Packsaddle claims. They were held by local people without means to push the development to a point where a large tonnage could be produced. This, in connection with the long wagon haul of ten miles to the nearest important settlement, kept the output limited strictly to local demands of the nearby agricultural communities.

In December, 1917, these properties were taken over and placed under one head, by R. S. Talbot, of Spokane, Wash., who successfully developed the large magnesite deposits of eastern Washington. The area of the coal property involved in the transaction is upward of 1200 acres. It is roughly oblong in shape lying northwest and southeast along the strike of the coal seams. The workable seams so far proved are nine in number and range from 30 in. to 12 ft. in thickness. The measures are interspersed with shales and sandstones of Cretaceous age. The average dip is 60 deg. to the southwest, and the principal seams upon which development work has been done produced a remarkably clean low-ash coal, which parts readily from the top and bottom rock.

A typical analysis of several of these seams is as follows: Moisture, 3.60 per cent.; volatile, 41.50 per cent.; fixed carbon, 52.60 per cent.; ash, 2.30 per cent.; sulphur, 0.40 per cent.

The present development work is being confined to the Brown Bear seam, and it was on this 5-ft. seam that the most noteworthy development work was carried on by the former owners. The old development work consists of a 400-ft. rock tunnel cutting the seam at a vertical depth of 80 ft. From this intersection, 2000 ft. of entry has been driven and from this opening mining has produced about 50,000 tons of coal; this was removed prior to the taking over of the property by the Talbot interests in December, 1917.

As soon as the new management took control of a slope 500 ft. long with a parallel air course was sunk, and at that depth about 800 ft. of entries have been driven in the seam; the coal exposed on this entry and air course above with a 30-ft. chain pillar is to be worked by 100-ft. rooms with 100-ft. pillars between.

A modern headframe has been built and a hoist and skip installed, together with all neccessary surface improvements. At present the skip delivers 20 tons of coal per hour to the tipple, and as the underground development progresses this capacity will be rapidly increased. The coal brought to the surface is run over bars which grade it into lump, egg, nut and slack, all except the slack being delivered to a 350-ton bin. At the present time this coal is being disposed of to the ranch-

ers and others who come to the mine with wagons and haul the product away. About 7000 tons of coal was produced in 1918, all from development operations.

A main development tunnel, 9 x 7 ft. in the clear and to be 6000 ft. long when completed has now advanced several hundred feet; it is designed to intersect the whole series of coal seams at an average vertical depth of 500 ft. The portal of this tunnel is slightly lower than the present entry on the 5-ft. seam. When this seam is reached, entries will be driven and connection made with the present workings. This main tunnel is about one mile north of the present slope on Horseshoe Creek, and at this point a lower camp has been established which will be the terminal of the railway spur now under construction. When the improvements are completed the upper camp will be abandoned.

A modern tipple, capable of handling 1000 tons per day, will be built at the lower camp. A powerhouse (almost completed) contains a boiler, Atlas-Corliss engine, an alternating-current dynamo of 125-kw. capacity and a Laidlaw-Dunn-Gordon compressor; the latter for supplying air to the drills in the tunnel. There is also a ventilating fan.

A railway spur ten miles in length is under construction from the main line of the Teton Valley branch and will terminate at the tipple site. The grading on this spur has been completed to the mouth of Horseshoe Canyon, a distance of 17 miles, and track laid to this point. Bad weather has interrupted railroad construction along the canyon which, however, is not a serious problem; and it is confidently expected that the branch will be completed to the lower camp by early spring. Pending its completion, coal is being hauled on sleds from the 500-ft. slope operations to the temporary railway terminal over a good easy grade recently completed. It is expected that the daily output of the mine will soon be from 200 to 300 tons. After the cross-cut tunnel is in operation it is expected to increase this output to 600 tons per day.

There are 40 men employed of whom 15 are engaged in underground work. The underground force is to be increased as rapidly as conditions will warrant in order to get out the tonnage intended. During the past summer and autumn 30 new buildings have been constructed, which include family cabins, quarters for single men, boarding houses, store buildings and so on. A saw mill was installed to supply lumber for these buildings and most of the new buildings at the upper camp are so constructed as to be readily moved when the camp is abandoned.

The various coal seams have been tested out and the property thoroughly surveyed and proved by surface work in addition to its 500-ft. slope development. From the data obtained as a result of this work and the uniformity of the seams, for a distance of two miles along their strike, it is conservatively estimated that the coal available above the level of the long cross-cut tunnel now being driven will be in excess of 130,000,000 tons.

The future of this field is decidedly promising, chiefly on account of the geological location and the quality of the coal. Though close to the Wyoming border, high mountain ranges intervene and shut off communication and competition with this part of Idaho. It is one of the most extensively developed areas of the state, embracing as it does within 50 miles of the mine three large sugar factories using approximately 50,000 tons of coal per year and three other factories of similar capacity now in process of construction. The comparatively short railway haul from this field to the extensive Snake River valley settlements will afford a splendid local market for the output of this field; it is far shorter than from the nearest Utah or Wyoming coal mining operations, which are the only likely sources of competition. Coal famines, in this rich agricultural territory from now on, should be a thing of the past and a good market is assured for the output of these deposits, for a long time to come.

Illinois

By Martin Bolt

Assistant Director, Department of Mines and Minerals, Springfield, Ill.

DURING the year 1918 the coal mines of Illinois will probably produce a larger tonnage than ever has been produced in any year of coal mining in this state. There are a number of reasons why the production will be greater than last year, and I will give these reasons.

Martin Bolt

In the year 1917 there were in operation in Illinois 810 mines employing 80,893 men, who produced for the fiscal year ending June 30, 1917, 78,983,527 short tons of coal by working 179 days as an average.

The mines are divided into two classes, shipping and local. The shipping mines, working 215 days and employing 78,056 men, produced 77,412,054 tons. The local mines, working 154 days and employing 2837 men, produced 1,571,473 tons of coal.

On the other hand, in the year 1918 there were in operation 967 mines, employing 91,372 men, and these men produced for the fiscal year ending June 30, 1918, 89,979,469 tons. There was an increase in the number of mines in operation of 157, of which 47 were in the shipping class and 111 in the local class. The increase in the number of mines in operation does not necessarily mean that there are that many new mines; a great many are old mines reopened, and very probably when the present conditions no longer prevail they will be closed down.

The new mines that have been opened are of the large up-to-date kind, equipped with all the latest improved mining appliances. They will in nearly every instance be large producers of coal.

In addition to the increase in the number of mines in operation, the number of men employed has also increased to a large extent, notwithstanding the fact that a great many mine workers are in the service of the country overseas and have done their part toward winning the war.

The figures given below are for shipping mines only, and are nearly correct for the first ten months of the year 1918, with estimates for November and December.

The number of short tons produced was 89,325,962, and there were 88,200 employees, who worked an average of 245 days. These figures, together with the tonnage produced by the local mines, will bring the total above 90,000,000 tons; had the production of July been maintained for the entire year, the production, in round numbers, would have been above 112,000,000 tons.

In addition to the increased production the conditions of the mines of the state have been improved to a marked degree; the coal companies are taking a keen interest in matters of safety, which will surely bring a reduction in the number of mine accidents, because the mines will be made more safe.

The coal industry of Illinois did its bit during the time of the war, and it can be depended upon to do the very same thing in times of peace.

Indiana

By John Ogilvie

State Mine Inspector, Indianapolis, Ind.

COAL output in the state of Indiana during the fiscal year ending Sept. 30, 1918, broke all records for this state. There was some time lost on account of the shortage of railroad cars, which was the principal cause of throwing some mines idle more than they otherwise would have been. There were some days lost during the year on account of strikes, but these

were few. Owing to the large demand for coal in this country, the miners of Indiana stood loyally behind the Government, laid aside their petty grievances and kept at work while their differences were being adjusted. Some time was lost on account of incendiary fires occurring at several mines. All the surface plants at two mines were completely destroyed, and this threw these mines idle for about sixty days.

The production of coal for the fiscal year was 28,795,682 tons, including block and bituminous coal. This was divided as follows: Block coal, 551,184 tons; bituminous coal, 28,244,498 tons. The wages paid by the various coal companies was $39,776,916.19, making an average wage earned per employee of $1424.06 per year.

The total number of mines employing more than ten men in this state is 245, of which 51 are new operations sunk during the fiscal year. This is a large increase of new mines for this state, and everything points to a bigger production of coal in the future.

The American Coal Co. at Bicknell has the largest producing mine in this state, having produced 5900 tons in one day. This company has sunk another new mine, which is being equipped to hoist over 6000 tons per day.

More Days Worked This Year

The average number of days that the coal mines were in operation during the year was 254. This is an increase of thirty days over last year. There was a considerable shortage of men during the year, owing to a large number of the best miners joining the army.

The stripping plants and small mines, those employing less than ten men, do not come under the jurisdiction of the mining department, but the following is a summary of the production of these operations for the fiscal year.

Steam shovel mining has become an important factor in the coal-producing industry in this state. These operators maintain an organization known as the Coal Producers' Association, which has twenty-one members who produced approximately two million tons during the fiscal year ending Sept. 30, 1918. The stripping system is used where the overburden can be removed economically by steam shovels or drag lines. From 15 to 40 ft. of overburden is removed. Bucyrus shovels with 8-cu.yd. dippers and 90-ft. booms are used where stripping is heavy. Nos. 3, 4, 5 and 7 beds of bituminous coal and Brazil block coal are excavated by this method. Stripping plants are operated in ten counties in the state.

There are about 300 small mines in the state, and it is estimated that the production of these for the year was 2,500,000 tons. Most of this coal is consumed within the state. Taking the production from mines coming under the jurisdiction of the state mine inspector, stripping plants and small mines, the state had a total production for the year of 33,295,682 tons.

The general condition of the coal market will, in my opinion, continue to hold good for some time to come. The war being at an end will allow other industries to get back to their regular work of producing commodities for which there is a great shortage, owing to many factories being employed in the manufacture of war supplies.

There were 114 fatalities in and around the mines during the year. The number of tons produced per fatality was 292,067. These fatalities were from the following causes: Falls of coal, 3; falls of slate, 49; mine cars, 15; mine motors, 3; explosions of powder, 8; gas and gas explosions, 14; exploding shots, 3; mine cages, 3; falls into shaft, 3; other falls, 2; electricity, 6; railroad cars, 4; miscellaneous, 1.

The mining laws in this state are inadequate, and it is to be hoped that the coming Legislature will place on the statute books some laws that will state specifically the safeguards to be used to protect the workmen.

The movement for prevention of accidents and knowing how to protect oneself from the dangers met with in coal mines is finding favor with the miners and operators in this state. The Federal Bureau of Mines is installing a rescue car to be located at Terre Haute; also a mine rescue station at Vincennes, to be equipped with oxygen apparatus for fighting mine fires and explosions. This station will have a large motor truck, which can reach the scene of any disaster in that district in a very short time. Many first-aid and rescue teams will be organized in the mining districts, through the use of these two stations.

The Knox County coal companies have in operation a mine rescue station at Bicknell, which has two separate teams of men, who can be reached in a short time should they be required. This team has done good work all over the state in the past year in fighting mine fires, and it also helped at the mine explosion at Clay, Ky., where 62 men were killed by an explosion of gas.

The Industrial Board is using its best endeavors in assisting the Mining Department to carry out to a complete development the safety movement.

Iowa

By L. E. Stamm
Secretary, Iowa Mine Inspectors

COAL-MINING conditions in Iowa were good throughout almost all of the year 1918, better, in fact, taken as a whole, than for a number of years past. As a usual thing the Iowa mines work fairly well during the fall and winter months of the year. With the coming of spring the small local mines of the state shut down, to again reopen some time in August. The larger mines, and especially those having railroad connections, and supplying railroad coal, work through the summer, but not with as lively a business as in the winter, when commercial coal is shipped in addition to the railroad trade.

In 1918 the mining business was good during the months of January, February and a part of March; then there began to be a slump that may be traced to two conditions confronting the trade just at that time. The first was the warm weather prevailing in March, which caused a falling off in the commercial coal trade, and the second was that many of the contracts for coal for railroad use expired in March and the roads refused to enter into contracts paying the Government price for coal at the mouth of the mines.

The operators of the state refused to sell for less than the Government price. The result was that no contracts were made for some time, and many of the mines of the state were idle a part of March, all of April, and some of them until well along in May. Mines in other states were working, and this caused a large number of miners from this state to leave for other mining fields. It is estimated that between 1200 and 1500 miners left the southern Iowa fields for this reason.

Prices Higher Than Before

Iowa used to be one of the favored states, getting her coal at a low price by reason of having so many mines within her borders. During the war all this has been changed, until present coal prices are the highest in the history of the state. Beginning with the prices fixed at mine mouth by the Government in August, 1917, the price of coal has been advanced on several occasions. An advance was given to the miners and other mine workers by the Washington agreement, which became effective in this state on Nov. 1, 1917. The Government allowed this advance to be added onto the cost of coal at mine mouth, and later the fuel committee fixed the price of coal placed in the bins here in Des Moines at $5.65. A general freight rate advance became effective in June, 1918, but no advance in coal was made here until September following, when the fuel committee fixed the price for Des Moines, put in the consumer's cellar, at $6.15 per ton. This is almost double the price paid for the same kind and grade of coal three years ago.

The year 1917 was a banner year in the production of coal in this state. Previous to that time the highest production of the state had been but little over seven million tons of coal per year. In 1917 this was increased almost two million tons, the actual figures for 1917 being 9,049,806 tons produced, while 15,464 men were given employment in and around the mines of the state for that year. This increase in tonnage was made with but few more men employed than in former years, and was possible because the mines were able to keep going the most of the summer months.

Had the mines of the state been able to keep busy during the months of

March and April, 1918, I am sure that the production of coal during the past year would have compared favorably with the amount produced in the banner year 1917. Taking everything into consideration, however, I am inclined to think that the 1918 production will be slightly less than that of 1917. I believe the returns will show about the same number of men employed in the mines. The actual figures as to production, men, etc., will not be available until about Feb. 1, as statistical blanks are sent out from this office Jan. 1 and the operators are given 30 days under the law in which to file their reports.

Labor conditions were exceptionally good in and around the mines of the state in 1918, and but few suspensions of mine work were caused by strikes or disagreements. These were chiefly on account of differences as to the meaning and terms of the agreement between the miners and operators, as affecting some particular work done in the mine, or some action taken either by the miners or operators.

Hard to Predict Future of Coal Industry in State

As to the outlook for coal production in this state for 1919, so many things have entered into the production and distribution of Iowa coal the past few years that it would be hard to make a sensible prediction for the coming year. Of one thing we are assured, and that is that the mines of the state are in good condition for future production. Since the war is over and the Government has ceased to control the output and distribution of coal as in war times, fuel from other states may now come into this commonwealth, and this may have the effect of lessening the production of Iowa coal.

Of another thing we are assured by the operators themselves, and that is that since the Government has exercised control in a measure over the mines of the state, the operators have a much better system of cost accounting and know better now the cost of coal production. This will be of value to them in the future. The year 1918 has seen a number of new operations in the state, and all these new mines are being well equipped for future production. We can therefore hope much for the coal business in Iowa for the year 1919.

Michigan

By M. D. King
Chief Assistant, Department of Labor, Lansing, Mich.

THE output of coal from the mines of Michigan during the twelve months ending Nov. 30, 1918, amounted to 1,501,053 tons. This included 154,303 tons of pick-mined coal and 1,346,750 tons of machine-mined coal. The details of operation are shown in the accompanying table. (See top of the next column for table.)

SUMMARY OF MICHIGAN COAL MINING STATISTICS FOR 1918

Number of mines in operation during the year	21
Average number of men employed	2,137
Average number of hours worked per day	7.8
Average number of days worked per month	22.4
Average daily earnings of each employee	$5.45
Aggregate amount of wages paid	$3,113,028.83
Total number of kegs of powder used	16,403
Aggregate tonnage of pick-mined coal	154,303
Aggregate tonnage of machine-mined coal	1,346,750
Total number tons of coal mined	1,501,053
Aggregate cost of output	$5,022,151.96
Average cost of coal per ton	$3.35

Missouri

By George Hill
Chief Mine Inspector, Bevier, Mo.

THE year 1918 breaks all records in Missouri's history in the production of coal. The total output reached approximately 6,000,000 tons, which shows a gain of 500,000 tons over 1917. This tonnage was produced in 32 counties, Macon, Lafayette, Barton, Adair and Ray counties being the chief producers.

Missouri is unfortunate, in comparison with some adjoining states, as our largest coal beds do not exceed over 5 ft. in thickness, and sometimes our largest annual tonnage comes from the Lexington seam, which averages from 20 to 22 in. in thickness. The mines have worked full time and practically every mine is in operation.

The production was curtailed in some respects in many counties on account of the shortage of labor, as many of the miners have joined the colors. The operators and miners have worked in harmony this year, as there has been no labor disputes and both sides seemed to agree that it was their patriotic duty to produce coal.

The outlook for 1919 appears good, as numerous new mines will be in operation. With the return of the miners Missouri should produce more coal in 1919 than in any previous year of the coal-mining industry of the state.

Montana*

COAL production in the State of Montana for the year ended June 30, 1918, was the largest in the history of the state, in spite of some adverse influences which were experienced in the shape of a scarcity of labor and a shortage of cars. The increase was due to industrial activity, the demand being far in excess of the supply at all times.

During the year in question many new mines, mostly wagon operations, were opened, while some old ones temporarily abandoned were reopened and at present are producing coal.

The only labor trouble of any importance occurred at the mine of the Republican Coal Co. at Klein, in Musselshell County. At this mine the men were on strike for a period of about ten weeks. This reduced their output for the year by about 100,000 tons. With the exception of this strike, the year in question was free from labor troubles and as a general rule the relationship existing between the employer and the employee was pleasant, each striving to adhere to the conditions and obligations that all had assumed.

No great disaster, such as a mine explosion, occurred at any of the mines of the state. This avoidance of disaster has been due to the constant vigilance and care of the foremen, whose duties require them to oversee the welfare of the miners under their charge. There have been fatalities—too many of them—but just as long as coal mines are operated, injuries and fatalities will occur. All that can be done is to safeguard the workmen as far as it is humanly possible to do so. This has been done, and the Department of Mines is receiving the active coöperation of the management of the various mines throughout the state. Many operators not only coöperate, but also take the initiative, devising means for reducing injuries and fatalities. This is particularly true of some of the larger companies that are sparing no expense to bring about conditions of safety in their mines that are decidedly worthy of emulation.

Twenty-one fatal accidents occurred in the coal mines during the year from July 1, 1917, to June 30, 1918.

*Abstract from Annual Report of ex-State Mine Inspector John Sanderson.

SUMMARY OF COAL-MINE OPERATIONS OF MONTANA

Number of mines reporting to the Mines Department	88
Machine operators employed	228
Loaders	1,032
Miners	1,496
Inside daymen	1,151
Outside daymen	839
Total number of men employed in and about the mines	4,746
Total tonnage produced	4,515,414
Total number of lives lost	21
Tons produced per life lost	215,020
Number of men employed per fatal accident	226
Number killed per thousand men employed	4½
Number of kegs of powder used	101,913
Tons of coal mined by machine	1,961,743
Tons of coal mined by hand	2,553,671
Per cent. of coal mined by machine	43%
Per cent. of coal mined by hand	57%
Total value of mine output	$9,525,386

New Mexico

By W. W. Risdon
State Mine Inspector, Albuquerque, N. M.

A YEAR of unusual activity in coal mining was witnessed in New Mexico in 1918. No strikes or labor disturbances have occurred during the year. The demand for coal has been unlimited. The railroads have given the mines excellent service. There has been but little loss of time on account of a shortage of cars. The scale of wages paid to the mine workers has been the highest ever known. Yet notwithstanding these favorable conditions, the state has fallen behind the production for the year 1917. The decrease totaled fully a half million tons less than the mines are capable of producing.

The output for the year 1918 amounted to 4,037,726 short tons. Of this 47,050 tons were anthracite; 3,229,387 tons bituminous; 761,289 tons semi-bituminous. The value of the coal mined amounted to $9,876,361. In operating the mines 40,506 tons were used; 1,126,935 tons were shipped to the coke ovens, and 2,870,265 tons were sold. The coke ovens made 607,241 tons of coke, valued at $2,448,494.57.

The number of men and boys employed at the mines were: Miners, 3070; day men underground, 837; boys underground, 45; 876 day men and 45 boys were employed on top; 315 men were employed at the coke ovens. There were 1,209,401 tons of coal cut by machines and 2,828,325 tons pick-mined.

Making an analysis and comparison of the reports of the large companies for the years 1917 and 1918, and reducing them to a like basis, we find the average loss per man per day for the year 1918 is 0.83 ton. This—including only the three largest companies—amounts to over 300,000 tons. The companies have been short of men and have been compelled to hire everybody who came looking for work. The high scale of wages paid at the mines, together with the fact that coal miners were placed in a deferred class by the draft board, caused many men to seek work in the coal mines.

W. W. Risdon

Many of these men not only had no experience in the mines but were indolent as well. There were enough of these shiftless and inexperienced men, together with a few Austrians, who worked only enough to make expenses, to cut down the production and cause the loss hereinbefore mentioned. Daily records kept of the men who report for work in the mines show that for nine months there were from 25 to 35 per cent. of the men laying off every day.

In addition to large reinvestments of earnings into permanent equipment, thus making for efficiency, the large companies are devoting much time, attention and money to bettering the social and living conditions of their employees. During the year several hundred thousands of dollars have been spent in the mining towns in renovating, repairing and repainting the dwellings; in removing old shacks and replacing them with comfortable houses; inclosing the yard of each dwelling with a fence; in building coal-houses and providing garbage cans and making a general clean up of the camps.

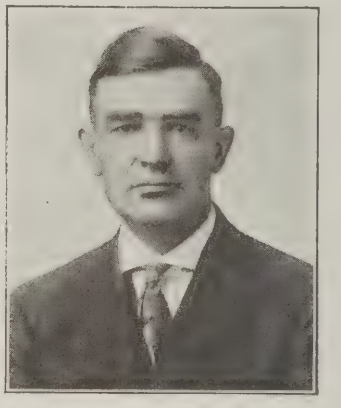
The living conditions of the average mine worker in these towns is equal—if not superior—to the living conditions of the workingman in the large towns of the state, and far ahead of anything New Mexico has to offer in its country districts. No additional revenue will be derived by the companies for the improvements mentioned. Comfortable homes will lessen the desire to move about and will work for a more friendly feeling toward the employer. When men are contented they have a higher efficiency than when they are dissatisfied. The respect and confidence of its employees is the biggest dividend paying asset a company can have.

North Dakota

By W. H. Robinson
State Engineer, Bismarck, N. D.

THE estimated coal production of North Dakota for the calendar year 1918 is about 1,000,000 tons. This estimate is based on the assumption that the same increase over that of the previous year will be shown in 1918 as was attained in 1917. The forecast for the coming year is difficult and uncertain. It is considered doubtful if the production for 1919 will exceed that of 1918 to any great extent. This belief arises from the scarcity of labor and the high wages demanded by what miners are available. Much, will however, will depend upon how rapidly and in what numbers men are released from the army.

South Dakota



By Otto Ellerman
State Mine Inspector, Lead, So. Dak.

AS A coal-mining state South Dakota has, as yet, gained but little prominence, and for the year just ended the annual production was 10,100 short tons. The entire output was used in the immediate vicinity of the mines as a domestic fuel, no railroad shipments being recorded. The annual output shows a decrease over the previous year, the decline being due to a shortage of labor. With wages ranging from $4 to $6 per day, the operators experienced difficulty in obtaining satisfactory help and in some instances were forced to suspend work. With the return to normal times this barrier to the development of this natural resource will be removed and steady increases may be anticipated.

The mines, with the exception of those in Dewey County, are situated so far from railroad transportation as to make shipments to other localities impractical. This condition limits the output to an amount that can be used locally. Until railroads enter the area, no great progress will be made in coal mining. The coal is a lignite that disintegrates readily upon exposure to the air and would not withstand being transported any considerable distance. This, however, can be overcome by briquetting; tests have shown that this can be done with success and at a profit.

The field is a large one, and the estimate by the U. S. Geological Survey places the amount of minable coal in Harding and Perkins counties alone at over one billion tons. In addition to these counties, coal is found in commercial quantities in Meade and Dewey counties. Near Isabel and Firesteel, in Dewey County, the coal beds have an average thickness of 6 ft. and have been opened by entries several hundred feet in length.

To determine the extent of these deposits drilling has been done, and the figures obtained indicate over one million tons as available. The Lindt mine at Firesteel and the Robbins mine at Isabel have near railroad connections, the road being only two miles distant. In past years coal was hauled to the railroad and shipped, but during 1918 the scarcity of labor prevented this. The coal is clean and sells at the mine for $4 per ton.

Otto Ellerman

At the November election in this state, Amendment F to the State Constitution carried by a large majority. This authorizes the state to engage in the coal-mining business and for that purpose to acquire by purchase or appropriation all necessary lands, structures, easements, tracks, rights-of-way, equipment, cars, motive power, implements and materials. The amendment further provides that the state may pledge its credit to secure funds for this purpose. No expenditure of money, however, shall be made except upon a vote of two-thirds of the members of each branch of the Legislature.

To investigate the coal possibilities within the state, a commission was appointed and its report will be made to the next Legislature, which meets during the early part of 1919. The action of the Legislature in voting funds for the development and commercializing of the coal deposits will depend largely on the report of the commission.

The deposits are of sufficient size to warrant operations on a large scale, and with railroad connections and a briquetting plant, there is no good reason why South Dakota cannot be supplied with an economical fuel from its own fields. There were no accidents attributable to the coal-mining industry during the past year.

Ohio

By Jerome Watson

Chief Deputy and Safety Commissioner of Mines, Columbus, Ohio

THE coal industry in Ohio during the year that has just closed reached a magnitude never before attained. Ohio produced 41,677,986 tons of coal during the year 1917, and reports collected from the various coal-producing districts indicate that there will probably be an increase of 20 per cent. in production for the year 1918, bringing the tonnage to a figure something near 50,000,000 tons.

Lake shipments alone amounted to 29,388,242 tons from April until navigation closed Dec. 4. This represents cargoes amounting to 28,153,317 tons and 1,234,925 tons for fuel, shipped from the docks of Toledo, Sandusky, Huron, Lorain, Cleveland, Fairpoint, Ashtabula, Conneaut and Erie, and transported to these docks over the Baltimore & Ohio, Hocking Valley, Toledo & Ohio Central, Pennsylvania, Wabash & Lake Erie, New York Central and Delaware & Lackawanna railroads.

Unusual Demand for Fuel

The demand for fuel was unusual, and every effort was put forth to meet it. Of material aid in this respect was the fact that there was no such shortage of cars as was experienced during 1917. In the early part of 1918 such a shortage made itself felt pretty generally over the state. This was most acute in the Hocking Valley, and was the cause of the mines of that district averaging only about three days a week for the first three months. However, the evolving of the "zone system" greatly facilitated the supplying of cars, and during the summer and fall most of the districts had a car supply of from 80 to 100 per cent., while practically all districts reached a supply of 100 per cent. during the last two months, when the signing of the armistice closed many of the mines.

Another factor to consider when viewing the fact that the tonnage will probably not reach a figure so high as anticipated, is the shortage of labor due to many of the miners being of military service age. While many old mines that had been abandoned for years were reopened, and hundreds of small mines were opened up during this period of unusual activity in the coal business, it is estimated that there were no more men employed in 1918 than in 1917, if as many. In 1917 the mines averaged 51,286 employees. In spite of this the deputy mine inspectors of this state reported over 1600 mines operating during the last year.

The past year's record is indisputable evidence of the patriotism of the Ohio miners, for during the critical period through which we have just come, when the slogan was always "Produce More Coal," there were no labor troubles. True, the fixing of prices by the United States Fuel Administration left less cause for disagreement, but the customary petty disputes were noticeably absent.

The stripping operations of this state are coming to take an important place in the coal production. Figures for 1918 will show a marked increase over 1917, when more than 1¼ million tons were produced in this manner.

Ohio mines were singularly fortunate in having experienced no serious explosions or mine fires through the pressure of producing a high tonnage. While any accident causing a single death or injury is regrettable, the total number of such accidents reported for the year 1918 was in no way exceptional in proportion to the output, the total number of fatalities being 147. Of these, 91, or 62 per cent. of the entire number, were caused by falls of roof. Thirty of the total number of accidents occurred in Belmont County. There was quite an increase in the number of deaths due to this cause as compared with 1917, when 62, or 55 per cent. of the total number, were due to falls of roof—the total number of fatalities for 1917 being 112.

There was a decrease of four in the number of deaths due to mine cars, the total number being 17. There were eleven deaths from miscellaneous causes, an equal number having occurred from such causes in 1917. Six were the result of falls of coal, an increase of two; five were attributable to motors, an increase of three; six to explosives, an increase of one. The remainder of the fatalities occurred as follows: Three from railroad cars, two from gas, two from electricity, two from shots blowing through rib, one from a mining machine and one from a premature explosion.

Increase Shown in Output

All of the larger coal-producing counties showed increases in the number of fatalities. Belmont County reported the greatest number—43, as compared with 31 in 1917; Jefferson County showed 22, an increase of 4; Guernsey County which reported 15 fatalities in 1917, had an equal number in 1918; Athens County, 14, this being an increase of 2; Perry County, 14, an increase of 8, and Tuscarawas County, 10, an increase of 2.

Undoubtedly the closing of the year witnessed the final abandonment of a great number of the small mines, but if the present car situation continues, with the miners returning from military service, there is no apparent reason for a falling-off in the coal mining activity for the coming year.

Oklahoma

By Edward Boyle

State Coal Mine Inspector, Cumberland, Wyo.

THIS country's participation in the great conflict in Europe enabled the mines of Oklahoma during the year ending June 30, 1918, to work almost continuously. Assured of prosperity, operators made many substantial improvements on their properties. The miners also showed great loyalty toward the Government by overlooking many petty differences, and as a result the numerous shutdowns caused by local troubles, which prevailed before the war, were almost entirely done away with. The production of coal was thus greatly increased.

But a peculiar condition exists in Oklahoma, one that does not exist in the old coal-mining states and one that has retarded the mining industry to a great extent. The coal area being largely on Indian lands was segregated by the Government and has been leased to the operators of the state through the Secretary of the Interior on a royalty basis. Several years ago the Secretary of the Interior decided that it was unwise to make any more leases, and as a result there are thousands of acres of coal in the State of Oklahoma as yet undeveloped. Congress, however, eventually provided for the sale of coal and asphalt Indian lands, and many tracts have been sold recently while the rest is subject to sale at any time.

Edward Boyle

This is going to bring about the rapid development of the coal fields of Oklahoma, and will be the means of this state forging to the front and coming to be one of the foremost among the states of the Union in the production of fuel. There is a vast area of the state underlaid with a good grade of bituminous coal.

The mines of this state, generally speaking, generate large quantities of gas and a dust of a highly combustible nature. This requires strict legal regulation and supervision by the Mining Department in order to safeguard the lives of the miners. I think that under the conditions of the past year and the greater carelessness arising from the rush of business, accidents both fatal and nonfatal are naturally to be ex-

pected Under these conditions the public and the Mining Department should feel fortunate that under the existing circumstances, the state was able to mine 4,489,064 tons of coal with a total of fatal accidents numbering only 33. Concerning these fatalities, the reports show that seven men were killed by falling rock, five by runaway trips, one fell down a slope, six were killed by dust explosions and five were burned by gas. The other fatalities were caused by accidents of a minor nature, such as windy shots, etc.

The chief inspector does not desire to take unto himself all the credit for this enviable record. The coal operators are entitled to share in it because of the way they have coöperated with the department in this work; the district inspectors also were largely instrumental for the successful way the industry has been conducted during the year.

The tonnage produced in the year ending June 30, 1918, and the different grades of coal made are as follows:

Lump	633,688
Nut	180,035
Pea and slack	468,841
Run of mine	3,206,500
Total	4,489,064

The gains in the different grades of coal over the year ending June 30, 1917, are as follows:

Lump	84,911
Nut	48,319
Pea and slack	14,702
Run of mine	479,435
Total	627,367

Pennsylvania

By Frank Hall
Deputy Chief, Department of Mines, Harrisburg, Penn.

ACCORDING to most careful estimates, the production of coal in Pennsylvania in 1918 will reach about 272,373,714 net tons, of which 99,514,334 net tons were anthracite and 172,859,380 net tons bituminous. The coke production will probably be 24,000,000 net tons. The number of employees in the anthracite region was 147,868 and in the bituminous region 172,600.

The number of fatalities during the year was 1009, of which 541 occurred in the anthracite mines and 468 in the bituminous mines. In 1917 the production was 271,519,710 tons and the number of fatal accidents 1075. The record of the past year both as to production and accidents is one to be proud of, and this is particularly true regarding the fatalities. The usual dangers that meet the mine workers from day to day were increased by the number of unskilled men employed and by the frantic haste to produce coal, with the consequent carelessness on the part of the miners.

The Federal regulation of mining operations and of practically all the other branches of the coal industry has not, although a most radical innovation, proved an unmixed evil. Indeed the violent protests at first heard when the Government made known its intention to control and supervise the trade to a certain extent have been superseded in some quarters by expressions of positive approval. Perhaps the experience of the past two or three years may demonstrate the wisdom of closer relations between the Government and the business interests.

One of the results of the war, so it is predicted, will be a closer union between labor and capital. There seems to be a trend toward mutualism, but just what the outcome ultimately will be no one can tell. War is a leveler of all distinctions, at least temporarily, and it is probable that employers and employees having reached, amid the hardships of war, a juster and fairer view of their relations to one another,

Seward E. Button
Chief, Pennsylvania Department of Mines

may in the future work together with less of the antagonism that in the past has militated against competency, efficiency and social harmony. The great fact should be more generally apprehended that their interests are identical.

Profits from investment for the employer and compensation for service for the employee are still fundamentally necessary in the coal trade, as in other fields of endeavor. Beyond this, however, there should be consideration for the needs of the community. A fair profit to the operator, a fair wage to the employee, a fair price to the consumer (all of which is possible), and the coal mining industry would be conducted to a much greater degree than ever before in conformity with the Golden Rule—the rule that must sooner or later be the guiding principle in all business transactions.

The year just past has been one of particular stress in all branches of business, and the coal industry has been no exception. The war made an imperative demand for a maximum production of fuel, but at the same time depleted to a great extent the number of mine employees. However, notwithstanding the almost insurmountable difficulties encountered, the operators and employees both bent their energies to the fulfilment of the great task laid out for them, and the result attained in the way of production stands as a testimony to their loyal, patriotic, untiring efforts.

In addition to the shortage of labor the uncertainty of car supply was a potent factor in keeping down production. The epidemic of influenza also interfered greatly with output. But these difficulties will be helpful in causing greater activity at the mines in the future.

It is gratifying to know that the general readjustment from war to peace conditions is being made with much less friction and disturbance than was expected. In fact, few operations have closed down and few of the working forces have been reduced. Working overtime, an abnormal phase that has characterized the industry during the year, has been eliminated, and operations may now be expected to proceed with the usual celerity.

The cancellation of war contracts lessened to some degree the need of coal for many of the industries directly concerned in war work, but the delayed work of many manufacturing

concerns that was put aside to make way for manufacture for the Government will create for a considerable time, perhaps for several years, a heavy demand for coal.

There is, however, a difference of opinion as to the immediate future of the trade. Some of the state inspectors and some of the operators look for a continuance of the present heavy output, while others are of the opinion that our home industries, no matter how active they may be, cannot absorb the tonnage that has been consumed under war conditions. It remains a fact, however, that the many industries that were practically eliminated during the past two or three years, in so far as nonwar materials were concerned, will resume their usual line of manufacture with a greater energy and force than ever before. This will certainly mean a demand for fuel.

Unquestionably the labor situation is one of great concern. There may be a shortage of labor owing to the fact that the miners now in the service of the army and navy will probably not be released for months to come. And if the foreign countries should find it desirable to keep their citizens at home, and therefore stop migration to this country, the greatest source of labor will have been eliminated. In some parts of the mining region many of the men are anxious to return to their native lands to see the destruction that has been wrought by the contending armies, and to get a first hand acquaintance with the new conditions thay are led to expect will exist. Many of these men may never return to this country. It may be that the number of immigrants for some time to come may not exceed the number in 1917 and 1918. In the former year this was 295,403, and in the latter, 110,618. These figures present a marked contrast to those of five years earlier, when the number was 1,218,480.

Another element of uncertainty is the wage question. At present the miners are receiving high wages. Any reduction in their compensation before the necessities of life have been reduced might cause serious dissatisfaction and bring about an unsettled condition of labor that would be decidedly detrimental to coal production.

Texas

By Bruce Gentry
State Inspector of Mines, Rockdale, Texas

THE production of coal in Texas during the year 1918 differs little from the records of previous years, being about 1,500,000 tons of bituminous and 1,300,000 tons of lignite coal. The number of bituminous mines in operation was 18, and of lignite 38. One new bituminous mine was opened and two were abandoned; ten new lignite mines were opened and five abandoned.

Progress of development of the bituminous fields is very slow, and the present outlook is that few new mines will be developed in the near future. One of the largest producing companies operating in the northern part of the state has developed a large oil field adjacent to its coal lands. Naturally the production of oil is more lucrative than that of coal, and this condition does not tend to boost the coal industry in this section.

The lignite industry is progressing rapidly and the outlook is that many new mines will be developed during the coming year. One of two strip-pit mines are being contemplated, these to be located near Rockdale in Milam County. There is here considerable territory where the overburden is shallow.

Some of the larger power companies are making investigations and studies of different points along the lignite formation with a view toward locating a large central plant for distributing power over transmission lines to different parts of the state.

The fuel shortage which has made it impossible to secure bituminous and anthracite coal in some parts of the state has led to the use of lignite as a domestic fuel, and the results have been satisfactory, as people have found that the lignite is a good fuel for domestic use. This introduction to the use of lignite is doubtless a good thing for the people, as the principal fuel deposits of Texas are of these coals and it will be necessary to look more each year to lignite as a fuel for all purposes.

The operators and miners have coöperated with the Government in increasing production and in delivering cleaner coal as requested for war needs.

Texas has been practically free from strikes during 1918. There has, however, been considerable labor shortage in both the bituminous and lignite fields. Some mines have suffered from car shortage.

The mines of the state have continued their good record for a small number of fatal or serious accidents. Better methods of mining are being adopted at some of the mines, but at many there is room for improvement. The outlook is that all mines will be active during the coming year.

Utah

By A. C. Watts
Salt Lake City, Utah

UNLIKE 1917, the year 1918 has had few unusual or exciting incidents which influenced the coal industry in Utah. With the beginning of 1918, the excitement attending the entrance of this country into the world war had given place to a grim and steadfast purpose to do everything possible to help win the conflict, and our miners had settled down to work in earnest.

The mild fall and early part of the winter of 1917 had permitted a steady flow of coal and coke to the markets, and when on Jan. 8, 1918, winter began in earnest with heavy snowfalls, the domestic consumer, heedful of repeated warnings, had a goodly supply of coal on hand, and the retailer had coal in his yard. But, having ever before him the tales of severe shortage and suffering in the East, which was bound in an arctic grip, our local fuel administrator gave orders for heatless nights which resulted in many good people going to bed early with their socks on and the relinquishment by many of their cheerful grate fires. The attention of office men was also called to the wasteful habit of having windows open in the office to lower the temperature instead of shutting off the steam. Unfortunately, that was the only way the poor clerk had to get fresh air.

As a reward for our sacrifices, coal came from the mines in an uninterrupted stream, and in three weeks the fuel administrator rescinded his heat-

less night order and coal dealers beban to solicit business. By the middle of February the mines were running only two-thirds time. With the return of spring, the fuel administrator began urging the consumer to start storing for the coming winter, without at first meeting with much response. To the coal operator, it was important that the market be maintained so that the mines could be kept working full time, for in the spring quite a large proportion of the miners become restless and with high wages all over the country they were not content to remain idle part time and have their earnings reduced.

Mindful, however, of the past and apprehensive of the future, the domestic consumer and many industries began early in the summer to store coal, all except certain railroads. More care and intelligence has been exercised in storing large quantities of coal because of dearly bought experience in the past. When fall set in, and this year winter started early in November, almost everyone who could had from 50 to 100 per cent. of his season's coal stored in the bins, and dealers had a good supply on hand. Such universal storing was done that in October the mines commenced to have idle days and there were many cars of unbilled coal on hand.

Now that the war has ceased and the tremendous demands of war industries for fuel have been curtailed and even stopped, there seems no reason why there should not be an ample supply of coal for all normal demands in the intermountain region. Up to January, 1918, there had not been a time for 16 consecutive months when the established operators were caught up with their orders. The situation at the end of this year is much different, and the operators are now looking for new business.

No Disasters During the Year

Fortunately there were no disasters in the mines of the state during the past year. In one important mine the coal in an old part of the workings took fire by spontaneous combustion, and although strenuous efforts were made to load it out, it finally became necessary to seal off that portion of the mine. The area affected was near a district in which in times past the coal had been burned out, and there was considerable residual heat remaining in the strata. Earlier operators of the property had not left sufficient pillars in their advancing work and had not pulled these pillars in a systematic way. The result was a considerable sloughing of the pillars remaining, which caused the broken coal to pile up around their bases to a depth of several feet. With temperatures of upward of 150 deg. F., spontaneous combustion occurred.

The method of allotting railroad cars during 1918 has been the same as followed during the previous year—it is called the idle hour method and was described in the columns of *Coal Age* last January. The car supply throughout the year has been exceptionally good—much better than in 1917.

For the fiscal year ending Nov. 30, the production of coal for the state was 5,175,813 tons, as against 4,036,069 tons for the fiscal year ending Nov. 30, 1917, or an increase of 28 per cent. Apparently the increase is due to approximately a 20 per cent. growth in production of the older mines and 8 per cent. due to new mines and small operations. No new properties of any consequence were opened during the year.

Exact figures for the first ten months of the calendar year and approximate and estimated figures for November and December show that the total production for the calendar year 1918 amounts to about 5,302,070 tons. This includes 756,460 tons made into coke.

Hard to Keep Forces Intact

It has meant strenuous effort on the part of the operators to maintain an adequate force of men in the mines. In the main coal producing districts of the state, those of Carbon County, the coal miners constitute the greater part of the population. The War Department gave no deferred classification on the grounds of industry, and, as stated before, patriotism ran high in the camps. Because of the young men being drafted or enlisting, specialized work such as driving, machine running, mechanical and electrical work suffered. Construction work was extremely difficult to prosecute efficiently, as many skilled mechanics had left for the cantonments, shipyards and other direct war work. From one company employing about 2200 men, 182 entered the service of the United States.

However, a study of the average number of men working for this company shows that it managed to maintain a larger force than in 1917. This was largely due to efforts made to secure men, but the high wages paid, good living and working conditions and prospects for steady work undoubtedly exerted a great influence. The same conditions should hold true for the whole district.

The turnover for this same company was about 100 per cent. as against 107 per cent. during the previous year. A large turnover of course affects the efficiency of an organization besides being directly the source of great expense.

The curves of average production per miner and per man employed in and around the mines shows a decrease from last year, and its steadily declining curve for this year. This is undoubtedly due to the large turnover for both years, but it may also arise from the increased wages the men earned.

The prospects for 1919 are not very clear. The mines of the state can easily supply all demands and with steady work overproduction instead of a shortage is to be feared. New properties opened in Wyoming and Idaho will increase competition which, if pushed to the limits reached in past years, will mean hard sledding to the weaker organizations.

Virginia

THE estimated production of coal in the State of Virginia for the calendar year 1918 was 10,100,000 tons. The total number of mines in operation—drift, slope and shaft—was about 313. The total number of fatal accidents occurring in the mines during the fiscal year ending Aug. 31, 1918, was 41. These arose from the following causes: Falls of roof, coal slate, rock, etc., 23; falls of top coal, 2; mine cars and locomotives, 8; suffocation from gas, 1; explosives, 3; electricity (shock and burns), 2; other causes, 2. The total number of all accidents, fatal and otherwise, entailing the loss of two weeks' time or less was 887. Permanent disabilities numbered 7, while the number of men hurt but losing less than two weeks' time amounted to 546.

Washington

By James Bagley
State Mine Inspector, Seattle, Wash.

DURING the first ten months of the year 1918 the coal mines of the State of Washington produced 3,488,008 short tons. This, with the estimated tonnage for November and December, will make the output for the state about 4,200,000 net tons for the calendar year 1918. This is the largest output this state has yet had and is an increase of about 200,000 tons over 1917.

The largest production was recorded in the month of August, when there was 137,343 days of labor performed, an average of 5430 men working 25.3 days and producing 379,965 tons for the month.

It is estimated that 95,000 tons of coke was produced at the mines in 1918, or about the same amount as in the previous year. This does not include the coke produced at the plant of the Seattle Lighting Co., located at Seattle, Wash. Fifty-seven mines and openings of all kinds operated during the year, with an average of about 5800 men employed, this being an increase of 500 employees over the previous year. They worked an average of 270 days.

While the production during the past year was the largest the state has had, it could have been increased if the market demanded it. A shortage of labor reduced the output at some of the mines during the summer, due to the large number of men drafted into the army and to many of the mine employees securing employment at the shipyards on Puget Sound. In the closing months of the year no labor shortage was reported.

The mines of the state are operated under agreement with the United Mine Workers of America. No serious labor trouble occurred during the year, the operators and their employees both working together for larger production.

The number of fatal accidents was large because of an explosion at the Burnett mine on Aug. 28 in which twelve persons were killed. The mine was worked with approved safety lamps and the explosion was thought to have occurred when one of the firebosses ignited a shot when gas was present. Thirty-three fatal accidents occurred to Dec. 21. These were due to the following causes: Falls of roof, 12; mine cars and locomotives, 3; gas explosions, 1; coal dust explosions, including gas and dust combined, 12; electricity, 1; suffocation in chutes, 1; falling down chute, 1; surface, 2.

Many improvements have been made in and around the mines during the past year tending toward the safety and comfort of the employees. All mines that generate explosive gas, in any quantity, have been placed on approved safety lamps. Mine rescue equipment has been placed at all mines where over twenty men are employed. Wash and changehouses, for the accommodation of the employees, have been built at all mines where a majority of the men have petitioned for them. New cottages and up-to-date hotels have been built at several of the mines for the accommodation of the employees, and on the whole the living conditions improved over former years.

COMPARATIVE TONNAGES, BY COUNTIES, FOR 1917 AND 1918—LAST TWO MONTHS ESTIMATED

County	1917	1918
King	1,314,366	1,347,300
Kittitas	1,741,237	1,776,500
Lewis	130,578	179,600
Pierce	606,449	618,500
Skagit	1,000	6,400
Thurston	204,688	267,500
Whatcom	4,841	4,200
Totals for state	4,002,759	4,200,000

C. J. Smith has opened a new mine at Ravensdale on the Northern Pacific Ry. A new preparation plant is under construction. Two beds that underlie those formerly worked at Ravensdale have been opened, and prospecting is being done on other measures that may be opened later. A new mine is under development at Bellingham known as the Bellingham Coal Mines, under the management of John C. Eden and Michael Earles. The seam of coal on which this mine is opened is classed as a good grade of subbituminous and was worked in the early history of the state, and coal shipped therefrom was sold in the San Francisco market. The old mine was abandoned about 35 years ago. Part of the output of this mine will be used at the plant of the Superior Portland Cement Co., at Concrete, of which Mr. Eden is president.

Contracts have been let and work started in sinking a shaft 300 ft. to a newly discovered 12-ft. bed of coal on the property of the Wenatchee Orchard Land Co. in Moses Coulee, near Wenatchee, Wash. The coal is classed as sub-bituminous and is thought to be about the same in quality as that mined in Lewis and Thurston counties. If development proves this field to be as extensive as it now promises, it will mean cheaper fuel for that part of central Washington, as coal is now shipped from King and Pierce counties to supply that market.

The problem that confronts the Washington coal operators in competing for business with surrounding districts and fuel oil is to find a market for the smaller grades of coal produced at the mines. In some of the districts, especially King and Pierce counties, where the coal is mined on the heavy pitches, the proportion of slack and pea, in some cases, runs as high as 50 per cent of the output, causing the market to be supplied with a surplus of these grades of coal.

The Pacific Coal Co., the largest producer of commercial coal in the state, some years ago installed a briquet plant near its mines which produces a briquet from this coal that is widely used on the commercial market. During the past few years it has carried on experiments to develop the use of powdered coal. During the last year it has spent considerable money in creating a market for the powdered coal, and during the last year some of the largest office buildings in the city of Seattle have changed from fuel oil to powdered coal, claiming it was cheaper than fuel oil at the present price and eliminating, to some extent, the smoke nuisance attendant upon coal and oil as ordinarily used.

No shortage of coal has existed during the past year in this state. During the last two months of the year there was a falling off in the demand for domestic fuel, due to the mild weather and the fact that the domestic consumer had stored his fuel during the summer and fall months as advised by the state fuel administrator.

West Virginia

SPECIAL CORRESPONDENCE

THE only figures obtainable on coal production for 1918 in West Virginia are those covering the fiscal year ending June 30, 1918. These reveal a material increase over the preceding fiscal year, and it is probable that were figures available for the calendar year of 1918 still further increases would be shown unless the sudden softening of the coal market following the signing of the armistice terms caused a slump in operations sufficient to offset gains made throughout the rest of the year.

The total production of coal in West Virginia during the period between July 1, 1917, and July 1, 1918, was 80,674,913 gross tons, which reduced to net tons gave the state a total production of 90,355,903 tons. This was an increase over the previous fiscal year of 868,261 gross tons, or 972,447 net tons. This large tonnage was produced by 71,075 inside employees and 18,272 outside employees, but only 710 more inside employees and 2542 outside men were used in the latter year to bring about the increase given.

There were 667 companies with 1203 mines in operation during the fiscal year ending June 30, 1917. This number was increased to 793 companies with 1359 mines during the year ending June 30, 1918—an increase of 126 companies and 156 mines. Despite the fact that a less number of men were engaged in the manufacture of coke during the 1918 fiscal year than was the case during the previous year—the figures being 2518 as against 2570—yet there was an increase in the coke manufactured, the figures being 3,122,722 tons as against 2,533,314 tons or an increase of 589,408 tons.

During the year the County of Summers began to produce coal for the first time. The county producing the largest tonnage during the fiscal year ending June 30, 1918, was McDowell, with a total production of 17,806,400 gross tons. Logan ranked next with 9,230,078 and Fayette next with 8,828,080 gross tons. The county producing the smallest amount of coal was Summers, with only 5338 tons.

It is estimated by the State Department of Mines that there were between 250 and 300 wagon mines in existence at the end of the fiscal year, many of which have ceased to operate since the signing of the armistice.

The mining industry labored under many handicaps at the beginning of the 1918 calendar year. Chief among these were inadequate transportation facilities and a totally inadequate car supply. With the advent of spring, however, the car supply improved, but floods interrupted operations. When the old system of car distribution was abolished and the mines were given an adequate car supply, production shot upward although affected by the drafting of men for the army, reaching a peak the latter part of July. The mines also gave promise of eclipsing their previous performance in October, when the influenza epidemic spread throughout the state, seriously affecting production. About the time the industry was beginning to recover from the influenza epidemic, hostilities ceased, and following a slum in the market, production dropped materially, reaching its lowest point during Christmas week.

While the coal trade is unusually quiet insofar as West Virginia is concerned, nevertheless coal men of this state look forward with optimism to the year 1919

On a rough guess it is estimated that the production for the calendar year of 1918 will exceed production for the fiscal year by 10 per cent., or that the total amount of coal mined in West Virginia up until Jan. 1 was about 100,000,000 tons. At least this is the opinion of the Department of Mines.

Northern West Virginia

By H. A. Williamson
Fairmont, W. Va.

COAL affairs in northern West Virginia are so involved one within another that it is an almost hopeless task to attempt to line them up. Government interest and control, or partial control, if not the most important feature of the year just past, is at least the one attracting most attention at the moment.

Some operators may not be quite satisfied with the coal prices fixed by the Government, yet it is evident that these prices have not in any way curtailed production. Just what will happen when this control is removed is, at this time, an important question; numerous opinions have been advanced, but in reality it looks much as if the operators, as a whole, are considerably more nervous about the removal of the price restriction than they were over its original application.

Pooling Meets with Approval

In a general way the same thing is true of the Tidewater Coal Exchange. Numerous operators were extremely pessimistic as to the pooling arrangement, but now a number of them are wondering what is going to happen when the system is abandoned.

In one direction at least the fixed price and pooling have helped the consumer. The snowbird, or wagon-loading, mines have not been so active this year. It cannot be denied that on the average the price of snowbird coal has been high, as that was the incentive for such operations; likewise it is undisputable that they require a longer time for loading cars than do tipple mines, hence if these cars are given to mines of the latter type they go out anywhere from 5 to 15 hours sooner than if the snowbird loaded them.

After all that has been written and said, the following seems a mere rehash, yet it is impossible to discuss events of this region for the year without bringing up again a condition which may now be justly stated to have become "chronic." In spite of statements at various times from the Federal management the car shortage here has been severe. It is possible that the average percentage of cars furnished has been somewhat higher than last year, but actually the long continued shortage has affected the situation in other ways than through a simple lack of cars. During the year 1917 and well into 1918 many of the larger companies carried extra equipment and continued work on various projects to increase tonnage. With the continued car shortage this equipment and work were gradually curtailed until at this time it is probable that there could not be a large increase in tonnage turned out other than what could be got by working six days a week with present equipment and labor. The longer this car shortage continues the more serious this condition will become, as there is, of course, a decided tendency for equipment and labor to shrink to a point where all factors balance. There is, for example, no incentive for the operator to repair the damaged mine cars on his car shop siding so long as he has more than enough in operation to take care of his output.

Due exclusively to shortage of railroad cars the labor actually available in the region had, up to the first of October, lost on an average two days' work from each week throughout the entire year. If we accept the figures as shown weekly by the U. S. Geological Survey, we find that almost without exception the car shortage has been more severe in northern West Virginia than in any other coal region. The Survey, in addition to showing time lost on account of car shortage, also shows percentage of time lost on account of what is termed "Labor Shortage," "Strikes," "Mine Disability," "All Other Causes" and "No Cause Given." The mere fact that other regions had more cars and were therefore able to work more days per week, would lead to the conclusion that the shortages due to these other headings listed by the Survey would be greater in northern West Virginia than in other regions; yet directly the opposite is the case. In many instances the percentage of shortage for the region due to these other causes is as low or lower than any other district, and almost without exception such percentages are far below the average for all regions. All this would certainly tend to show that both miners and operators must have made concentrated and well directed efforts to get out coal, and that had cars been available there would have been an increase in tonnage of at least 30 per cent. over what was mined for the year.

New Developments Under Way

Tonnage figures for northern West Virginia have always been difficult to obtain in any reasonable time. It appears now that the coal tonnage will be slightly less for 1918 than the production of 1917, while the coke production will be about the same or slightly more. About 20 new mines were opened, including a number on the Monongahela R.R., and one or two having arrangements for loading river coal. Work has been steadily continued on the new mines of the Consolidation Coal Co. at Wyatt, W. Va. There are three of these mines, at present loading coal over temporary tipples, with a steel tipple under construction to take care of the entire output, which is to be 4000 tons per day. It will be a relatively short time until this steel tipple is in operation. Construction work is being carried on at several other operations of smaller capacity, but owing to the car situation already outlined these new mines have had little or no effect on the total tonnage produced.

Based on normal production it can be said that there is a labor shortage; based on the car supply, however, it can be replied that the labor shortage has had no appreciable effect on tonnage.

The Lake trade, which has always been one of the mainstays of this region, suffered probably more than any other one branch of the business; 1917 saw this trade badly crippled, due to lack of cars and other items, but the shipments in 1918 will not be over 65 per cent. of those of 1917 and possibly not that much. This is due not only to lack of cars but also to Government instructions and orders applying fuel elsewhere under the zoning system. This is probably the only bad effect the zoning system has had on this region

Many Sales of Land Recorded

Numerous transfers of coal properties have been recorded during the year, and there has, as always, been ready purchasers for anything offered. Owners, however, have great faith in their holdings and transfers of large areas are rare—during the present year 200 acres being the largest one noted. There are purchasers for Sewickley coal and some small amounts of the Redstone Seam, while at points where they are available one or two beds below the Pittsburgh Seam are opened. The Redstone Seam is about 60 ft. above the Pittsburgh Seam, and the Sewickley about 60 ft. above the Redstone, while below the Pittsburgh about 635 and 705 ft. respectively the Upper and Lower Freeport occur. All these beds have received some attention and show at points conditions more or less favorable for operation, but from various causes such as poor quality, disturbances due to removal of Pittsburgh Seam, variations in thickness and limited area of workable coal there is a strong tendency on the part of experienced operators not to attempt their operation. The normal price of Pittsburgh Seam lands, with full mining rights, seems to be in the neighborhood of $500 per acre at this time.

A particularly gratifying feature of the past year has been the steady growth of safety work. It might appear that this phase of mining was somewhat overworked, yet when it is considered that nearly all mines worked shorthanded and with many inexperienced men, an increase in accidents should have been expected. This was, however, not the case, and unless something happens in the last few days of December, when the accident list for the year is compiled, it will be found well under the record for 1917. The compensation paid for accidents is a fair index of their extent and nature, and this figure will be in the neighborhood of 40 per cent. under that of last year.

For the future, miners and operators appear to feel that while it is quite possible, and more or less to be expected, that the removal of price restrictions and pooling arrangements will upset affairs for a time, the car

situation is bound to be bettered eventually and the available labor will increase with the letting up on Government contract work and other war activities—while sooner or later immigration, which has always been a large source of supply for coal-mine labor, will resume.

What will probably prove a most important event as affects the future, although it may not appear so at this time, is the entrance of the labor union into a field hitherto almost entirely nonunion. Labor had previously resisted attempts at unionizing and the operators had not been in favor of it. In a general way it appears to have been the opinion of all concerned that it was desirable, if not absolutely necessary, as a "war measure," and was carried out on this basis. The relationship between miner and operator has been most excellent in this region, and it is confidently expected that this will continue.

Many Byproducts Plants Building

Operations looking to future business appear on every hand. The Monongahela Valley Traction Co. is working steadily on a new electric power plant located at Rivesville, W. Va., which, with the plants and substations already operated by that company, will supply ample electric power to the various industries of the Monongahela Basin all the way from Morgantown to Clarksburg. The Domestic Coke Corporation, of Cleveland, is working steadily on the 60-oven byproduct plant located at Fairmont; these ovens are being erected under contract by the Koppers corporation. The Lymn byproducts producers of the Monongahela Valley Traction Co., also at Fairmont, are just about to start operation. If these producers are the success that is confidently expected, additional units will be started immediately. One or more of the large glass companies, so numerous throughout this region, are arranging for the erection of gas producers. All these operations call for the use of coal; not only this, they also will supply cheap fuel and power. This will attract allied industries whose normal growth will supply the final link of an endless chain demanding additional fuel and power, consequently more coal.

It would appear then that the future of this region now looks like one of rapid growth in many lines of industry calling for cheap fuel and power and, consequently, presents a bright prospect for the local coal trade. All of this makes for betterment of the region's interstate coal trade, which, of course comprises the bulk of the business.

It is the opinion of most operators that while the arrival of peace will, sooner or later, bring about a certain reaction or slacking up of industries, the extent of which it is impossible to predict, coal is nevertheless so essential that the coal industry will feel the minimum effect of such a reaction. Further, the enormous amount of reconstruction work necessary in various parts of Europe, the destruction of many coal mines in France and Belgium, and the complete or partial disorganization of the mining industry of Russia, Austria, Germany, Belgium, France and even Great Britain to some extent, will tend to stimulate American coal exports. The numerous vessels built and building under the American flag will furnish ocean transportation heretofore largely lacking. Altogether there will be a large market for coal in which this region will participate. And if the future prospects are not as brilliant as might be, they appear at least anything but gloomy or discouraging.

Southern West Virginia

By Josiah Keely
Kayford, W. Va.

Tables I and II give a monthly and yearly summary of car supply and loadings for the years 1917 and 1918 in the southern West Virginia fields served by the Chesapeake & Ohio Ry.

Josiah Keely
General Manager, Cabin Creek Consolidated Coal Co.

For the one interested in the study of statistics these tables will afford a history and a comparison.

In November, 1917, the car supply took a sudden and what as yet seems an unaccountable drop. The New River field, however, was favored to the extent of four supplies above other fields in December, ending that year eight suplies ahead.

With the beginning of 1918 the coal industry was well launched into the controversy with the railroads, the Government and the public as to what was causing the coal shortage. It did not seem to occur to publicity agents at first that the fact that the records showed the Chesapeake & Ohio was supplying only about half the cars required had anything to do with the shortage. The war industries started the previous spring had began clamoring loudly for coal, and there was considerable suffering in domestic markets. So uninformed was the general public that one railroad organ, which must have known better, had the temerity to publish an article laying the blame on coal operators, insinuating ulterior motives for curtailments and making an open accusation of unpatriotism.

In the meantime the operators of southern West Virginia began a daily record of the car supply. This was published, at first in obscure columns on back pages, but finally getting to front page space. The public was interested. As absurd as it may appear, it seems that it took an article by Jere H. Wheelwright, of the Fairmont field, written in simple language for the public, to make it understand that a mine was a dead proposition without railroad cars at the tipple.

Then there started in a system of railroading on paper. Allotments were cut down so that the railroad reports began showing increasing supplies of cars to the mines, apparently on the principle that if one loaf is not enough cut it in two and make two loaves of it. However, this was a good move, as all mines were more or less over-allotted, and some on what appeared to many an unfair basis.

By this time, early in 1918, the transportation failure had risen to be a national problem, recognized and discussed by the public; but before remedies could be applied, unheard-of wages were being offered in war work, especially at the Nitro plant below Charleston; furthermore, the selective draft had begun to operate. So by the time cars began to come in reality instead of on paper, many miners had become tired of two and three days per week and had left for the steadier industries.

About the latter part of June a new effect of war methods began to be acute. In order to get coal cars and keep them moving to and from the mines, all other freight was sidetracked and embargoed. It was not

TABLE I. COAL LOADING IN SOUTHERN WEST VIRGINIA FOR YEAR OF 1917

Month	New River		Kanawha		Coal River		Guyan Valley	
	Car Supply	Loaded	Car Supply	Loaded	Car Supply	Loaded	Car Supply	Loaded
January	4.45	209,830	5.47	276,765	5.62	77,155	4.79	341,560

Grand total Chesapeake & Ohio Ry								24,464,170 tons

unusual to experience curtailments of output on account of non-delivery of supplies, mine timber, feed, rails and repair parts. Labor was not sufficiently paid by the railroads to compete with other industries, so the branch lines over which the coal must be moved to the main lines were neglected. More money was spent cleaning up wrecks than would have made the needed repairs. It was not unusual to see a section foreman working alone or with only one man. Still, the cars did continue to come, and for the closing months of 1918 few operators on the Chesapeake & Ohio can say they did not have all they wanted.

A review of the year would not be complete without mention of the power failure beginning in the early part of the year and still causing occasional losses. The New River and Kanawha fields are supplied largely from the Virginia Power Co., at the mouth of Cabin Creek. This plant, instead of keeping a reserve unit, loaded everything up to the limit with increasing business, so that when one of its units went down New River and Kanawha had to alternate in power consumption. The Fuel Administration directed that these districts take a weekly turn working nights and early mornings. The miners stood it loyally for several weeks, then came strikes to force power service.

However, on the whole, labor loaded from one to two tons per day per man more than in 1917. This was due partly to the few loaders having a better chance to work, partly to the operation of the West Virginia thirty-six-hour-per-week law, and, I believe, largely to patriotism as nourished by speakers, placards and proclamations.

The increased value of coal made it possible for many companies that had not previously spent money on welfare work to extensively repair houses, build Y. M. C. A.'s and amusement halls, and to install playground equipment. Anyone passing through the field will be struck with the many evidences of prosperity as shown by the more attractive appearance of the camps.

On account of steady work the last half of the year, accidents per tons mined have been reduced as compared with 1917, when "big days" were attempted to make up for periods of car shortage.

Again turning to figures, the car allotment for this region has been cut just about half, it being 97,940 tons per day now, as against 189,260 tons in 1917. Also, the number of operations has nearly doubled. Probably few individual mines have put out more coal than in 1917, but with all the new operations the region shows an increase of nearly 20 per cent. over 1917, Guyan Valley showing as much increase as all the older fields put together.

Wyoming District No. 1

By George Blacker
State Mine Inspector, Cumberland, Wyo.

COAL production of District No. 1, of Wyoming, for the year ending Sept. 30, 1918, was the largest in its history. The mines have been working full time, with a scarcity of men. The demand for coal has never been greater than it has been during the past year. Each mine was taxed to its utmost, with each striving to meet the demand in order to bring the war to a victorious conclusion. Relations between the operators and miners have been pleasant, and only one object has been in view, that of winning the war.

Thousands of dollars worth of Liberty Bonds were purchased by the different

George Blacker

locals throughout the district. Every wage earner, man or woman, understood that he or she was expected to purchase at least one $50 bond. Permission was given the operators by the miners to collect 50 cents per man per month as long as the war lasted, this amount to be given to the Red Cross. I am indeed pleased to be able to report that our operators and miners during our national crisis have proved themselves patriots of the truest type.

The tonnage for 1918 was 6,244,731 short tons, as compared with 6,047,748 short tons in 1917, showing an increase of 196,983 tons. The number of fatal accidents for 1918 was 30 as compared with 36 in 1917, a decrease of six. Many new mines were opened during the year, but their development has been slow because of the great scarcity of men.

SUMMARY OF PRODUCTION, ACCIDENTS, ETC., OF WYOMING NO. 1 DISTRICT FOR FISCAL YEAR 1918

Number of counties producing coal	4
Number of shipping mines	45
Number of coal miners	1,628
Number of loaders	737
Total number of employees	5,165
Number tons of coal undercut by machines	2,195,254
Number tons pick mined or blasted off the solid	4,049,477
Total net tons of coal produced	6,244,731
Average days of active operation all mines	277
Number of fatal accidents	30
Number of nonfatal accidents	190
Number of employees to each fatal accident	208,158
Tons of coal produced to each fatal accident	172
Ratio of fatal accidents per 1,000 employees	5.7

Wyoming District No. 2

By R. V. Hotchkiss
State Mine Inspector, Sheridan, Wyo.

DURING the fiscal year ending Sept. 30, 1918, the production of District No. 2, Wyoming, was greater than ever before. The total tonnage produced was 3,172,538.25 short tons. The average number of eight-hour days worked was approximately 250.

CHIEF MINES OF WYOMING DISTRICT NO. 2—THEIR OUTPUTS DURING FISCAL YEAR 1918

	Tons
Sheridan Coal Mines, Nos. 7 and 8	326,932
Acme Coal Co.	421,492.1
Amalgamated Coal Corporation	116,312
Carney Coal Co.	413,953
Wyoming Coal Co.	430,099.9
Kooi Coal Co.	273,591
Cambria Fuel Co.	361,088.5
Owl Creek Coal Co.	309,384
Big Horn Collieries Co.	264,735
Poposia Coal Co.	254,950.65

Seven fatal accidents occurred, four arising from mine cars, two from falling coal and one attributable to explosives. One other fatality was listed, but was not charged to coal mining.

This made one man killed for every 453,219.75 tons produced, or 2.737 men killed for each 1000 employed. There were 48,068.76 tons produced for each nonfatal accident. Of these about 45 per cent. arose from falling coal or rock, about 25 per cent. from cars and 25.8 per cent. men were injured for each 1000 employed. The tonnage produced was disposed of as follows: To railroads, 1,265,068.05 tons; to commercial users, 1,752,855.46 tons. The slack shipped amounted to 219,786.2 tons.

As a whole, the miners have been well satisfied during the past year, laying aside their personal grievances

in order to back up the United States during the war overseas. The total number of men employed amounted to 2558. These men used 39,437 kegs of black powder, 13,108 lb. of giant powder and 73,008 lb. of permissible explosives. The working forces of the mines were distributed as follows: Miners, 1441; daymen, inside, 647; daymen, outside, 470.

The Sheridan No. 8 mine is the only new one now producing coal. It has been producing for ten months of the last fiscal year. It reaches a 47 ft. 6 in. bed of clean coal that is characteristic of the coal measures of northern Wyoming.

All the necessary improvements for bigger tonnage were maintained by all companies.

Seven certificates of competency were granted during the year, all of which were foreman's papers.

Alberta

By J. T. Stirling
Chief Inspector of Mines

THE estimated production of coal in the Province of Alberta for the year 1918 is approximately 3,250,000 short tons, and as the production for the year 1917 was 4,863,414 tons, this means that there will be an increase during 1918 over 1917 of approximately 1,300,000 tons. Exact figures are only available for the ten months ended Oct. 31, 1918. The total output during that period was 5,165,581 tons, as compared with 3,738,679 tons during the same period of the year 1917.

ALBERTA COAL PRODUCTION FOR TEN YEARS

Year	Output in Short Tons
1909	2,174,329
1910	3,030'757
1911	1,694,564
1912	3,446,349
1913	4,306,346
1914	3,821,739
1915	3,434,891
1916	4,648,604
1917	4,863,414
1918 (estimated)	6,250,000

The market for Alberta coal has been extended to such an extent that 433,331 tons were shipped into the Province of Manitoba during the first ten months of the year 1918, as compared with 188,647 tons during the same period of 1917. This additional market to a great extent was obtained owing to the fact that the shipments of coal from the United States to Canada were considerably decreased during 1918, and also because an extensive publicity campaign was started by the provincial government of Alberta warning consumers to put in a supply of fuel at the earliest opportunity; as a result a much larger proportion of the fuel required was stocked throughout the western provinces during the summer months.

Sixty-four new mines were opened during 1918 and 58 abandoned; the number at present in operation being 289 as compared with 283 at the end of 1917. Twenty-one fatal accidents occurred during the year as compared with 24 during the year 1917, and 119 nonfatal during 1918 as compared with 101 during 1917.

There are nine mine-rescue stations in operation in the province, three of these being installed in railway cars; 106 men have obtained certificates of efficiency in mine-rescue work. A large number of the bituminous coal mines in Alberta are now using electric lamps of the Edison type. There has also been a considerable increase in the number of coal-cutting machines in use.

Notwithstanding the increased production which has taken place during the past twelve months, the operation of the mines is being limited at the present time to about 60 per cent. of their capacity owing to lack of market. A large number of the mines—particularly in northern Alberta—have, during the last three months of the year, only been in operation on an average of about two days per week. It is estimated that if there had been sufficient market to keep the mines operating fairly steadily during the year 1918, that approximately 10,000,000 tons of coal could have been produced without increasing the number of men employed.

J. T. Stirling

DISPOSITION OF COAL PRODUCED IN ALBERTA DURING THE TEN MONTHS ENDING OCT. 31, 1918

	Short Tons
Sold for consumption in Alberta	2,884,259
Sold for consumption in British Columbia	85,147
Sold for consumption in Saskatchewan	1,147,590
Sold for consumption in Manitoba	433,331
Sold for consumption in Ontario	555
Sold for consumption in United States	113,151
Used in making coke	49,350
Used in making briquets	51,286
Used under colliery boilers	273,831
Put to waste	127,081
Total output (for ten months)	5,165,581

British Columbia

By George Wilkinson
Chief Inspector of Mines, Victoria, B. C.

DURING the year 1918 there was mined in the Province of British Columbia 2,881,915 short tons of coal, an increase of 195,354 short tons in comparison with 1917. Of this amount 1,866,571 tons was mined by the collieries of Vancouver Island, 195,191 tons by the collieries of the Nicola Princeton district, 819,785 tons by the collieries of the Crows Nest Pass district and 367 tons by the new mine at Telkwa in the northern district. The following are the comparative tonnages (in long tons) of the various companies and districts for 1918 and 1917:

COAST DISTRICT—VANCOUVER ISLAND

	1918	1917
Canadian Collieries (D), Ltd.	789,614	797,348
Canadian Western Fuel Co., Ltd.	731,922	658,427
Pacific Coast Coal Mines, Ltd.	82,629	150,538
British Columbia Coal Mining Co.	14,716	61,586
Nanoose Collieries	30,436	27,822
Granby Consolidated Mining Smelting and Power Co.	17,265	.....
Totals	1,666,582	1,695,721

The production of Vancouver Island collieries for 1918 was thus 1,666,582 long tons (1,866,571 short tons), a decrease of 29,139 tons (32,635 short tons) from the output of 1917.

COAST DISTRICT—SUBDISTRICT OF NICOLA PRINCETON

	1918	1917
Middlesboro Collieries, Ltd.	100,000	83,458
Merrit Collieries, Ltd.	.....	13,357
Pacific Coast Colliery	.....	206
Fleming Coal Co. (successors to Inland Coal and Coke Co.)	31,000	7,296
Coalmont Collieries, Ltd.	4,500	.....
Princeton Coal and Land Co.	38,778	46,926
Totals	174,278	151,243

The production of this district thus shows an increase of 23,035 long tons over the output of 1917.

CROWS NEST PASS DISTRICT

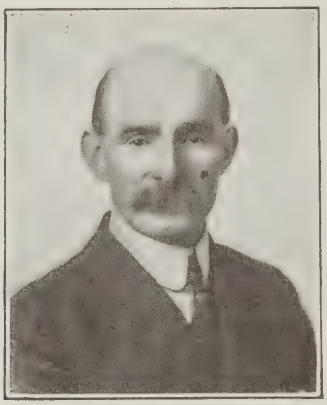
	1918	1917
Crows Nest Pass Coal Co.	605,979	456,686
Corbin Coal & Coke Co.	125,972	101,065
Totals	731,951	551,751

NORTHERN BRITISH COLUMBIA

Telkwa Collieries	328	.....

These two districts thus show an increase of 180,200 long tons, or 201,824 short tons, over the output of 1917.

Of the total amount of coal mined approximately 280,746 long tons or 314,435 short tons were converted into coke. The total coke production for British Columbia was approximately 190,696 long tons. Of this amount the Crows Nest Pass Collieries made 166,003 tons. The Canadian Collieries (D), Ltd., made 39,776 tons at its ovens at Union Bay, Comox colliery.



Strikes, mine fires and the ravages of the influenza epidemic have been responsible for a considerable loss in output during the year 1918. To these causes must also be added a serious shortage of labor during the year.

The monthly tonnages produced were fairly steady for the first seven months. The maximum tonnage for any individual month of the year was reached in August, when 249,237 long tons were mined.

On Sept. 4 a strike was called in the Crows Nest Pass district, a demand (based on alleged dangerous conditions) being made from the miners for the single-shift system. After the strike had lasted a month the mines were ordered opened by Commissioner Armstrong on the single-shift system pending an investigation into mining conditions by a royal commission to be appointed by the Minister of Mines who will report on conditions and determine if the demands made by the men for a single shift is warranted.

The commission is to be composed of one person recommended by the company, one by the men, and a chairman appointed by the Government. The commission has not yet started to investigate owing to the failure of the men to appoint a representative.

The strike in the Crows Nest Pass district was responsible for the loss of approximately 60,000 long tons, while the adoption of the single shift, and the ravages of the influenza epidemic,

GEORGE WILKINSON

have been responsible for the loss of approximately 75,000 more in the same district.

On Vancouver Island the East Wellington mine of the British Columbia Coal Mining Co. was closed down the first eight months of the year on account of a fire in the workings. This resulted in a loss of output of approximately 50,000 long tons. The influenza epidemic in this district has been responsible for a further loss of 50,000 tons.

NEW MINES OPENED DURING THE YEAR

The Granby Consolidated Mining, Smelting and Power Co. has opened and equipped a large mine at Cassidy's, Vancouver Island, where it has acquired a large area. The bed being mined is the famous "Douglas seam."

The mine is opened by three slopes driven in from the outcrop, one slope being used as a haulageway, one for a traveling road for the men and one for ventilation. The workings are being laid out along the most modern lines. The surface equipment is of the best, and nothing but the most up-to-date machinery is being installed.

About 100 acres of land has been cleared and some 75 houses built for the accommodation of the officials and employees. A water system has been installed and the houses are electrically lighted and fitted with all modern conveniences.

At Anyox the company has almost completed a battery of byproduct coke ovens, where it is the intention to make coke for use of the smelter at that point.

During the year the Canadian Western Fuel Co. started sinking operations on two shafts which will be known as the Wakesiah mine. Coal was reached in August at a depth of about 300 ft., the bed being the famous Wellington. The hoisting shaft is rectangular, 9 x 16 ft., and the air shaft is 10 x 8 ft. in cross-section. The surface equipment will be designed along modern lines.

The Harewood mine, which had been long closed, and was reopened by the same company last year, is producing approximately 1000 tons daily.

The new No. 5 mine opened by the Canadian Collieries (D), Ltd., at South Wellington is now producing about 300 tons per day. A good substantial tipple and surface equipment has been installed and this operation is capable of handling large tonnages.

In the Nicola Princeton district the Fleming Coal Co. has acquired the interests of the Inland Coal and Coke Co. and has reopened the mines, which have been closed for some time. The Coalmont colliery has also been reopened, and production started. A new mine has been opened in northern British Columbia at Telkwa and has been shipping a small amount of coal to Prince Rupert.

Improvements have been carried out at the various collieries during the year in an attempt to further safeguard operations. Safety inspectors have been appointed by some of the companies.

The Burrell gas detector has been adopted at all the collieries for testing for percentages of gas lower than can be detected by the ordinary safety lamp. In addition to the test made with this detector, mine air samples are taken monthly from the splits and returns of the various mines. These are sent to Ottawa for analysis, and records are tabulated and checked with the results obtained by the gas detector.

Some 4000 Edison electric lamps are now in use in the various mines of the Province. Training in mine-rescue work has been vigorously carried out by the various mining companies and by the Government of British Columbia.

The new Gibbs apparatus is finding much favor in British Columbia. The provincial government has installed six sets in its mine-rescue station at Fernie, which was the first consignment of apparatus of this type to Canada. Several of the mining companies are installing this apparatus, there being some twenty sets now on the way for installation.

A highly successful meet was held by the Vancouver Island Mine-Rescue Association at Cumberland on Sept. 2, and six mine-rescue teams competed for prizes. First-aid events were also held, and seven teams competed in the various events.

The annual meet of 1919 will be held in Nanaimo, and preparations are being made to make it a successful event. The Hon. William Sloan, Minister of Mines, was present at the meet held at Cumberland and presented the prizes to the winning teams. Mr. Sloan takes a keen interest in mine-rescue work, as well as all other things pertaining to the welfare of the workers.

Saskatchewan

BY E. PIERCE
Mine Inspector, Roche Percee, Saskatchewan, Can.

THE record output of coal for the Province of Saskatchewan, Canada, for the year 1917, was 336,726 tons, produced by 264 miners and 131 laborers from the 51 mines in op-

E. PIERCE

eration. It is noteworthy that there were no fatal accidents and only two nonfatal for the year. In the year 1916 the tonnage was 267,234, from 49 mines employing 236 miners and 131 laborers. There were no fatal accidents but an increase of two nonfatal over the record of 1917—four men were injured in or about the coal mines of the state in 1916.

The amount of coal produced in the province for the ten months ended Oct. 31, 1918, was 209,799 tons, and while figures are not available for the remaining two months, it is predicted that the record output of the preceding year will not be reached during 1918.

The mechanical equipment underground was increased slightly in 1917, when six electrical coal-cutting machines were in operation in the province, whereas four mining machines were used here during each of the previous two years. Of the four principal mines of Saskatchewan, two have electrical equipment. The Western Dominion Collieries, Ltd., produced 113,287 tons of coal in 1917 and is equipped with four electric coal-cutting machines and two electric motors underground; at the tipple of this company there is a mechanical box-car loader.

Coal—Now and Next Year

By C. E. LESHER
Statistician, United States Geological Survey

THE production of more than 585,800,000 tons of bituminous coal and lignite and 99,500,000 net tons of anthracite in the United States in 1918—a grand total of nearly 685,300,000 tons—has set a new high mark for the industry and the country; there is little likelihood of again reaching this record in the year now beginning, or even in 1920. Coal is produced in the United States to meet the requirements of industry and the domestic and public needs of the people of this country and Canada—not more than 1 per cent. of the output leaves the shores of North America. The needs of industry currently supplied, the mines have no choice but to stop, for, excepting by the larger anthracite companies, coal is not stored by the producer. Unless for production against a real or imaginary future inability to obtain fuel, the consumer does not invest in abnormally large storage piles of coal.

C. E. LESHER

The production of all kinds of bituminous coal in 1918 was ample for all needs. Despite the inroads of the influenza epidemic among mine workers and railroad employees, it would easily have been possible in November and December to have produced and transported 100,000,000 instead of 86,000,000 tons, and the year's total would have reached the coveted 600,000,000 mark. But the country did not need the coal. Even before Nov. 11, when word came that no more guns and shells and new plants for making these engines of destruction were needed, it was evident that the Fuel Administration's estimate of 623,000,000 tons from April to April would not be required; that, having seen that the coal mines and the railroads could get the coal into their stock piles, consumers were fast losing their anxiety.

In the six months from May 1 to Oct. 30, 1918, 319,000,000 net tons of bituminous coal were produced, six months in which the lowest monthly output was only slightly less than 51,000,000 tons and the highest more than 55,700,000 tons. At this rate 600,000,000 was easy and 624,000,000 not out of reason. The results, by months, for 1917 and 1918 are given in the following table; from January, 1915, to December, 1918, results are shown graphically in the diagram (Fig. 1).

Totals for the country as a whole do not begin to tell the story. Coal mines are not evenly distributed over the country, nor are consumers. Coal from each field has even in normal times fairly definite market territory outside of which it does not move, and under the zone system these areas are rigidly prescribed. A survey of the figures given in the table above throw light on the situation this winter.

PRODUCTION OF BITUMINOUS COAL AND LIGNITE IN THE UNITED STATES IN 1917, WITH ESTIMATES FOR 1918, BY MONTHS, IN NET TONS

	1917	1918
January	47,967,354	42,607,000
February	41,352,711	44,385,000
March	47,868,652	48,631,000
April	41,854,320	46,591,000
May	47,086,452	50,927,000
June	46,824,646	51,758,000
July	46,291,572	55,587,000
August	47,372,226	55,732,000
September	45,107,956	51,757,000
October	48,337,726	52,885,000
November	47,689,801	44,393,000
December	44,037,147	40,630,000
Totals	551,790,563	585,883,000

Demand for coal did not take an upward turn, following the depression of 1914, until late in 1915, and

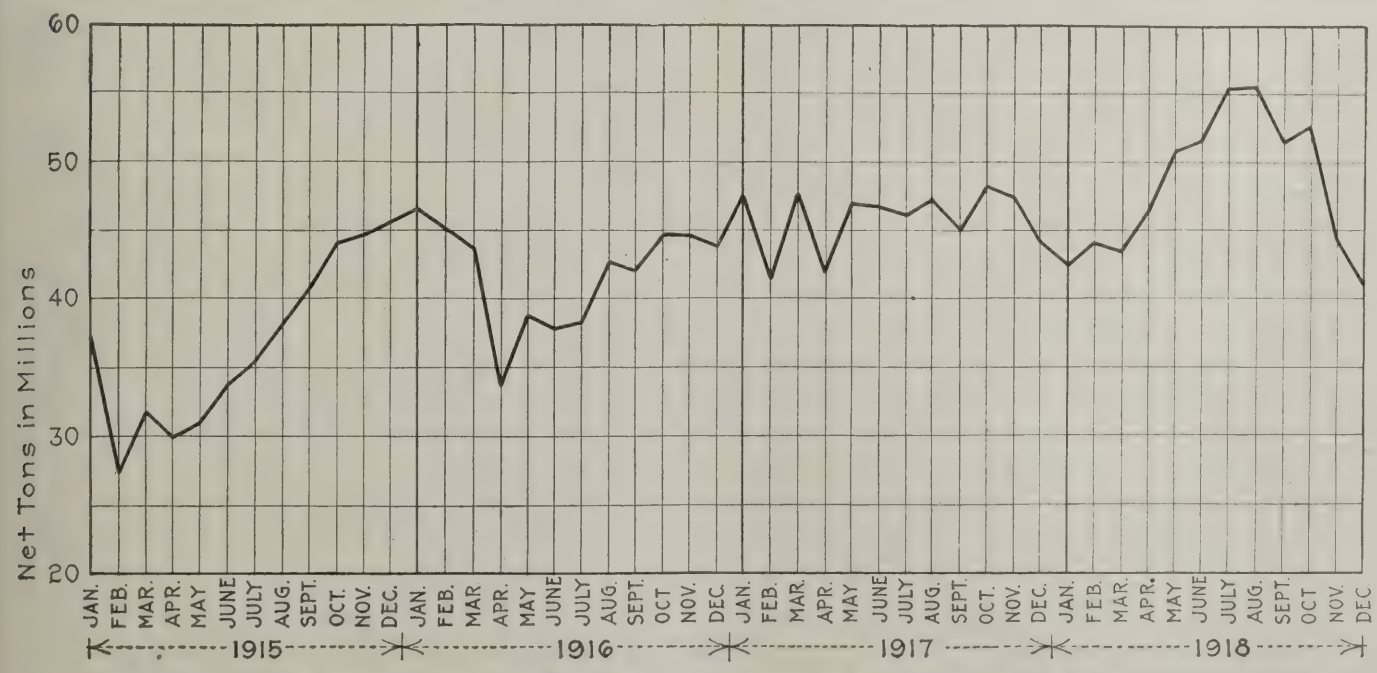


FIG. 1. PRODUCTION OF BITUMINOUS COAL AND LIGNITE IN THE UNITED STATES BY MONTHS, 1915-1918

then was sustained through 1916 only in the easternmost sections of the country. During the summer of 1916, while the mines in the Pittsburgh district were running full time, those in Illinois were suffering from their usual warm weather idleness because, by operating one, two or three days a week, all the coal anyone wanted in the latter state was supplied.

From October, 1916, to October, 1918, there were few dull moments in the coal business anywhere in the United States. Demand for coal to run the factories in the East that had sold munitions to Europe became, in the winter of 1916-17, more than the normal facilities could send forward, and Ohio and even Illinois coal was shipped to New England.

The mines that were to supply this intensified manufacturing activity along the North-Atlantic seaboard in 1917; Illinois, Indiana and western Kentucky, shipping in all directions, from Canada to the gulf and Nebraska to the Hudson, increased nearly 29,000,000 tons, or 31 per cent. There was nothing phenomenal in the record increase of these fields; a steady market permitted the operation of the mines in summer as well as in winter, something new for Illinois.

West of the Mississippi the fields from North Dakota to Texas gained 4,388,000 tons, or 16 per cent.; the Rocky Mountain fields 4,023,000 tons, or 14 per cent., and Washington 971,000 tons, or 32 per cent. In the south, Tennessee, because of strikes in the summer of 1917, made no progress; but Alabama gained 1,982,000 tons, or 11 per cent.

Compare these figures with the estimates for 1918. The most important group, that including Pennsylvania

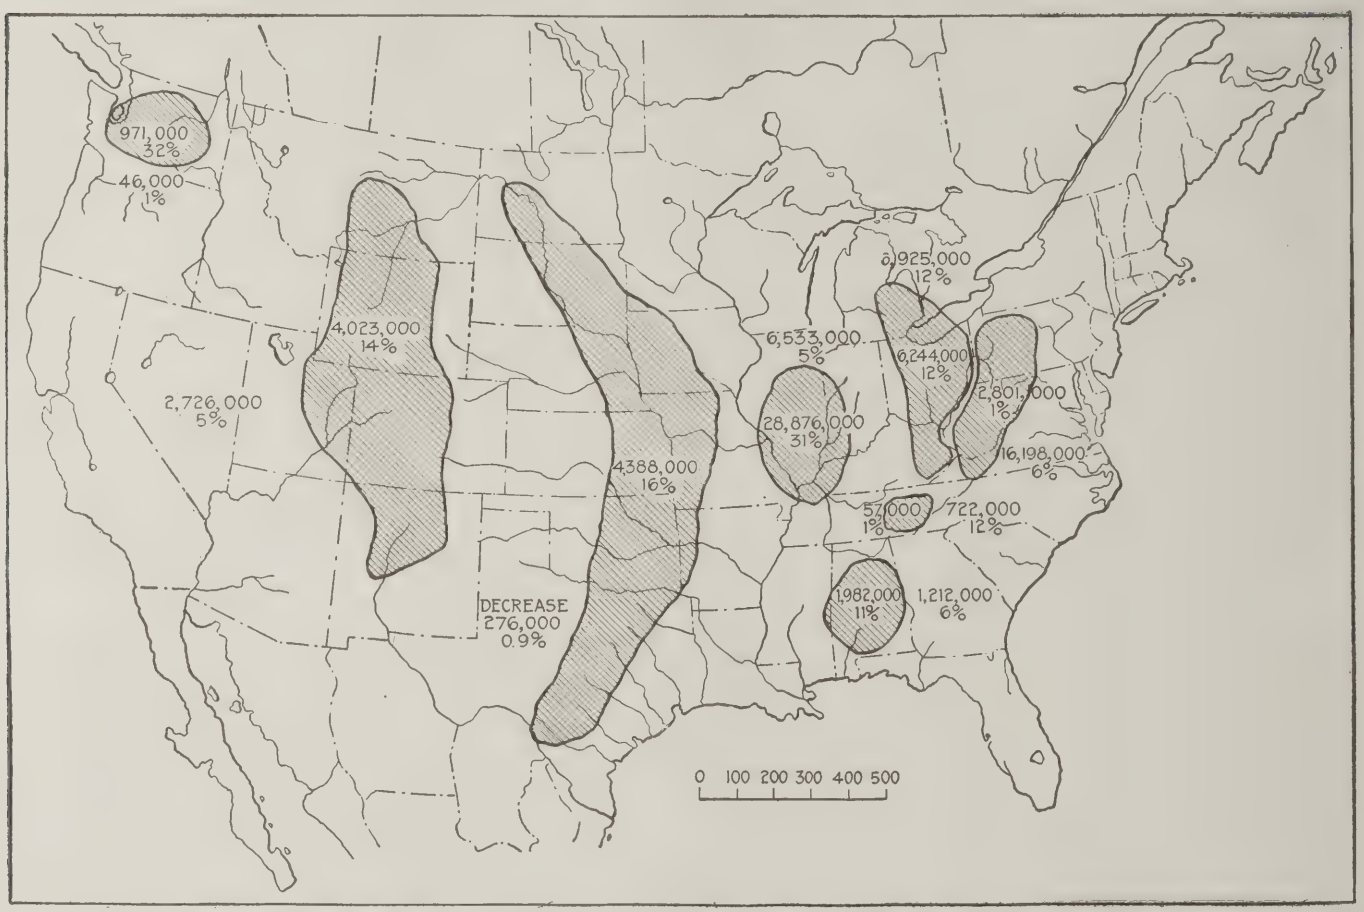

FIG. 2. MAP SHOWING GEOGRAPHIC DISTRIBUTION OF THE INCREASES IN THE PRODUCTION OF BITUMINOUS COAL IN 1917 AND 1918

The figures inside the lines give the increases in net tons and in percentages for the producing fields within the outlined areas for 1917 compared with 1916. The figures outside are 1918 compared with 1917

and as far west as the northeastern section of Ohio are in the four states of Pennsylvania, West Virginia, Maryland and Virginia, states from which, in 1916, came more than 54 per cent. of the bituminous output of the country and 60 per cent. of the total, including anthracite. And in 1917, with the greatest need for coal ever faced in this country (up to that time), a demand that fell heaviest in this section, this group of states—tributary to the North-Atlantic seaboard—produced but 1 per cent. more than in 1916; the group gained but 2,800,000 tons, while the other coal fields added more than 46,000,000 tons to their records.

Ohio and eastern Kentucky, with markets mainly west and north, gained 6,244,000 tons, or 12 per cent., and West Virginia—important because from here comes the major portion of our high-grade coal as well as the total supply for the North-Atlantic and New England States—gained 16,200,000 tons, or 6 per cent. In the country as a whole production of bituminous coal increased 34,000,000 tons, or 6.2 per cent. Eastern Kentucky, Ohio and Michigan gained 6,925,000 tons, or 11.6 per cent., about the same as the increase of 1917 over 1916. Tennessee increased 12 per cent. and Alabama 6 per cent. Illinois, Indiana and western Kentucky gained but 6,533,000 tons, or 5 per cent., against nearly 29,000,000 tons, or 31 per cent., in 1917. In the middle west the group comprising North Dakota, Iowa, the southwestern states and Texas had a slight decrease—

PRODUCTION OF BITUMINOUS COAL AND LIGNITE BY GROUPS OF STATES, 1915-1918

	Production, Net Tons		Increase 1916 Over 1915		Production 1917,	Increase 1917 Over 1916		Estimated	Estimated Increase 1918 Over 1917	
	1915	1916	Net Tons	Per Cent.	Net Tons	Net Tons	Per Cent.	Production, 1918	Net Tons	Per Cent.
Pennsylvania, Maryland, West Virginia and Virginia	247,442,000	270,922,000	23,480,000	9.5	273,723,000	2,801,000	1.0	289,921,000	16,198,000	5.9

* Decrease.
† Does not include production in California, Alaska, Oregon, Georgia, Idaho and Nevada.

276,000 tons, or 1 per cent., compared with a gain of 4,388,000 tons, or 16 per cent., the year previous. The Rocky Mountain states increased 2,726,000 tons, or 8 per cent., nearly equal to the gain of 1917 over 1916. Washington, with a gain of 32 per cent. in 1917, increased but 1 per cent. in 1918. The distribution of the increases in 1917 and in 1918 are clearly shown in the map (Fig. 2).

Measure these production figures against the estimated requirements as shown on the map in Fig. 3. In 1917 there were delivered to industrial and domestic consumers and public utilities in the states north of the Virginia-North Carolina state line and east of the Ohio-Pennsylvania state line, 100,940,000 net tons of bituminous coal. To meet the growing demand of war industries the Fuel Administration estimated that requirements of this section in the coal year ending March, 1919, would be greater by 16,680,000 tons, or 16 per cent., than the consumption in 1917. Similarly for Ohio, Indiana, Illinois, Kentucky and Michigan, with a consumption of 115,354,000 tons of bituminous coal in 1917, the increase was estimated at 15,542,000 tons, or 13 per cent.

The southern states, Tennessee, the Carolinas, Florida, Georgia, Alabama and Mississippi, were estimated to require 7,065,000 tons, or 38 per cent. more than the 18,441,000 tons consumed in 1917. The dock states, Wisconsin, Minnesota, and also the Dakotas, were expected to require but 1,689,000 tons, or 9 per cent. above their figure of 18,279,000 tons in 1917. States west of the Mississippi and south of the dock states consumed 48,210,000 tons in 1917, and requirements in the coal year 1918-19 were estimated to be greater by 11,000,000 tons, or 23 per cent. In addition,

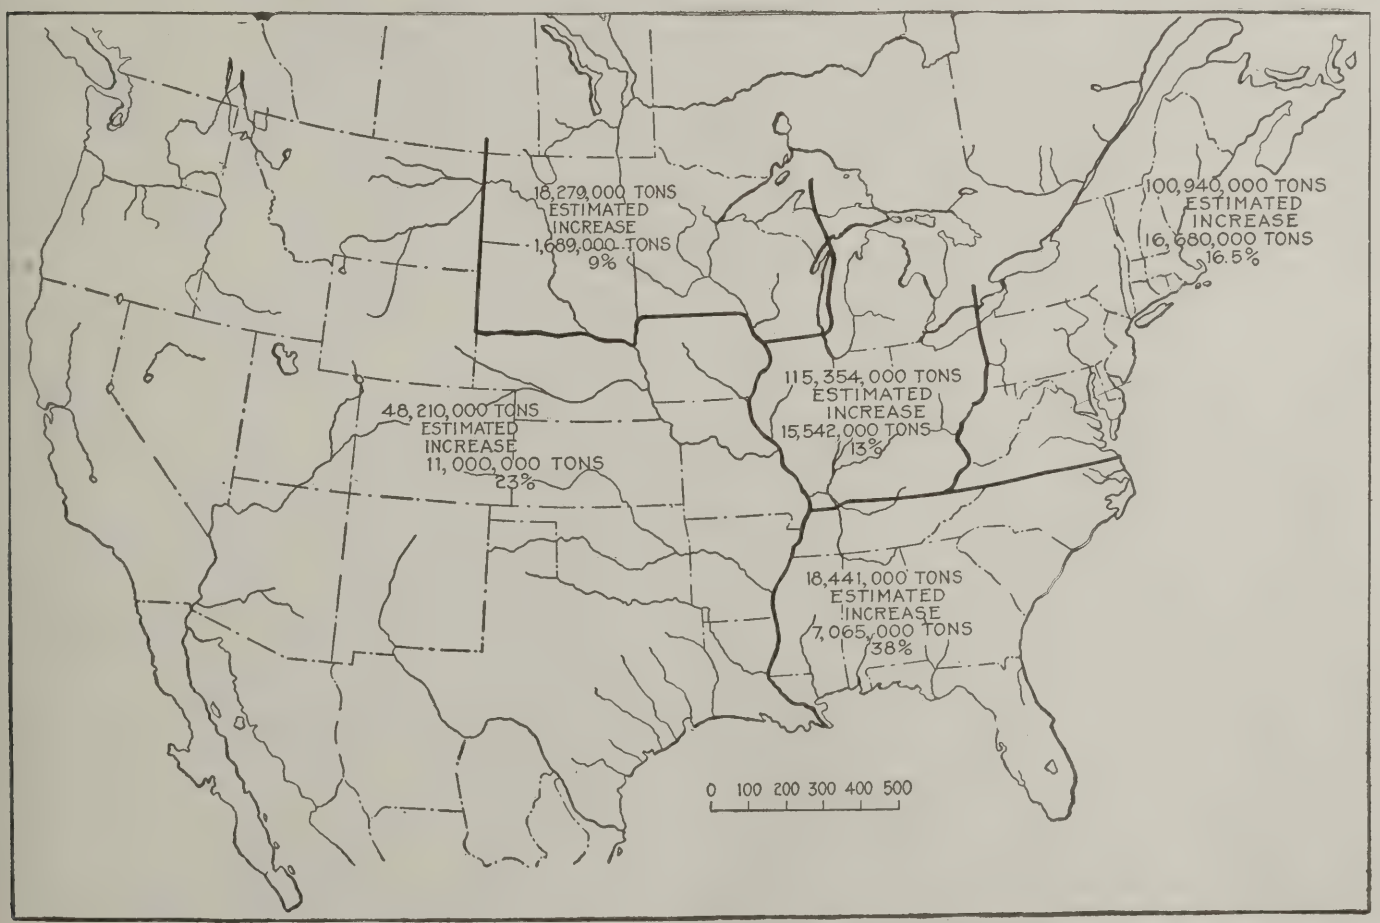

FIG. 3. CONSUMPTION OF BITUMINOUS COAL IN 1917 AND INCREASES IN THE REQUIREMENTS ESTIMATED AT BEGINNING OF COAL YEAR 1918-1919

The Fuel Administration estimated the needs for all industrial and manufacturing establishments, domestic consumers, public utilities and byproduct coke plants. Steam railroad fuel, colliery consumption and manufacture of beehive coke are not included.

the railroads had asked for an increase of 11,000,000 tons, or 7 per cent., from 155,000,000 to 166,000,000 tons, and the navy and Shipping Board asked for several million tons additional. About the only items that were not expected to increase were exports to Canada and abroad, and coal for beehive coke.

The coal fields of Pennslyvania, Maryland, West Virginia and Virginia, from which comes the supply of bituminous coal for the northeast section of the United States, also furnish the greater part of the tidewater supply for steamship bunkers, for the navy and for foreign export. They also ship high-grade coal, both low and high volatile, west by rail and by the lakes.

Lake cargo shipments from these states in 1918 were 16,506,000 tons, a decrease of 2,000,000 tons, compared with 18,453,000 tons in 1917. Deliveries at tidewater in 1918 were 37,489,000 tons against 31,181,000 tons in 1917, a gain of 6,300,000 tons, of which, however, 1,400,000 represented increased shipments to New England by water. All-rail shipments west beyond Ohio increased 2,700,000 tons, and all-rail and Lake Ontario deliveries to Canada, 1,300,000 tons. The net result was that, of the 16,200,000 tons increased production in these states, approximately 10,000,000 tons was available for consumption by all consumers, including the railroads, in the state of Virginia and north and east of the Pennsylvania-Ohio state line.

This increase of around 10,000,000 tons was accumulated after Apr. 1 to meet an expected increase in demand of less than 17,000,000 tons in the twelve months beginning with April. In other words, the northeast section of the United States, the sore spot on the map all through 1917 and early in 1918, has been taken care of this year.

The coal fields supplying the section around the lower lakes had increases in production in 1918 that have nearly equalled the expected gain in requirements. New high records in the movement of lake coal and rail shipments from Illinois to the northwest fully met the increased demands in that section.

In the south the anticipated need for an additional 7,000,000 tons did not materialize. Data have not yet been compiled to show to what extent the gains in production in Alabama—1,212,000 tons—and in Tennessee —722,000 tons—were augmented by increased shipments from Illinois, western and southeastern Kentucky and Virginia; but it is evident that less than half of the 7,000,000 tons additional was delivered in this section.

In the large central and western area shown on the map (Fig. 3), from which eastern coal was largely eliminated by the zones, the increase in production was less than 2,700,000 tons, sufficient, however, to meet actual demand.

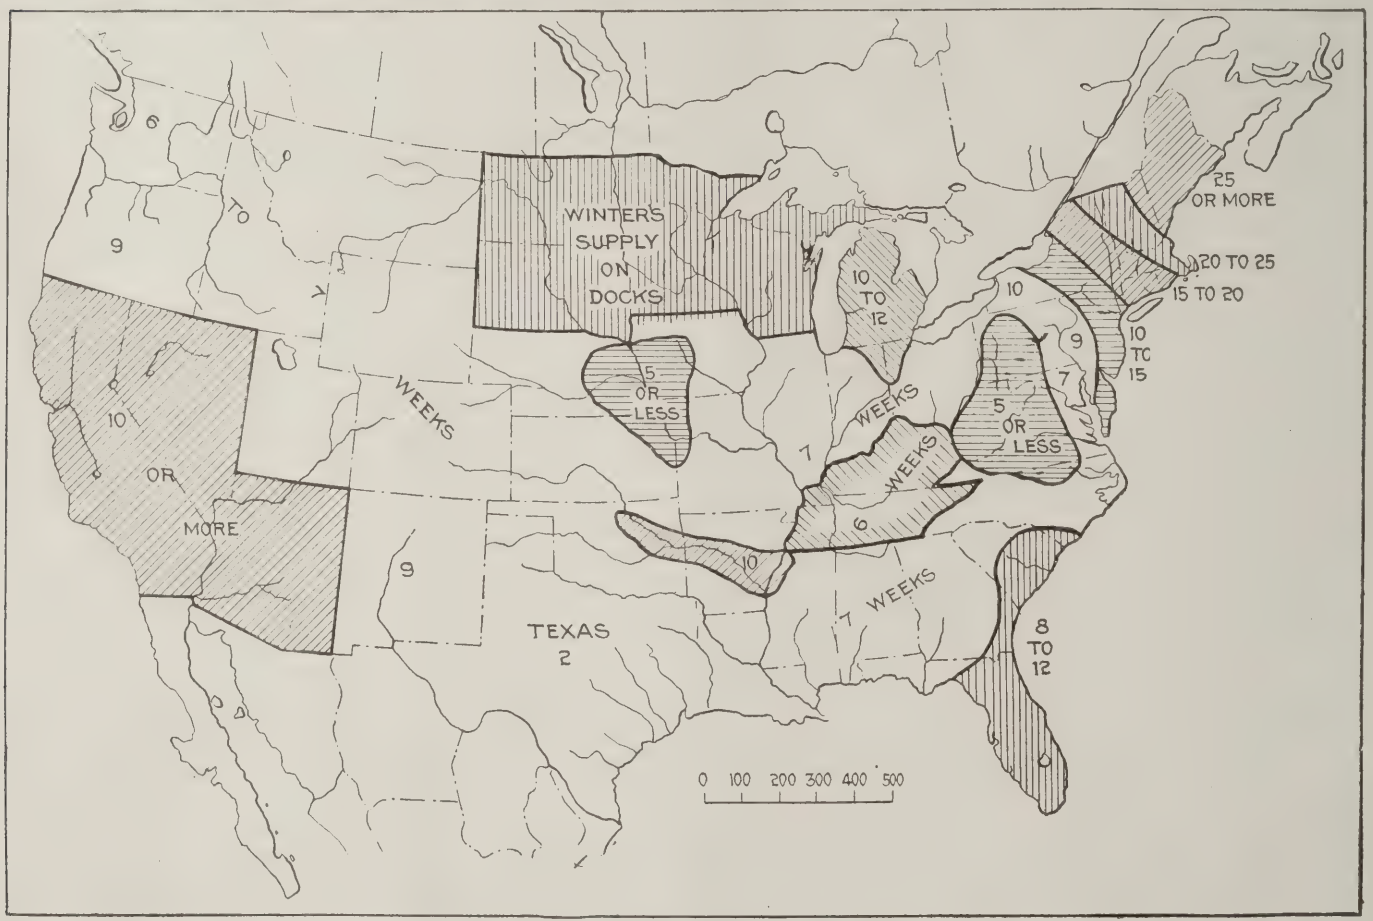

FIG. 1. NUMBER OF WEEKS' STOCKS OF SOFT COAL IN THE HANDS OF INDUSTRIES OTHER THAN STEEL MILLS AND COKE PLANTS ON NOV. 2, 1918

The situation on Nov. 2, 1918, with regard to stocks of bituminous coal in the hands of manufacturing and industrial establishments other than steel mills, and by-product coke plants, is shown on the map, Fig. 4. The most striking feature of the data thus shown is the generally high level of stocks of bituminous coal on hand immediately prior to the signing of the armistice, and the distribution of these stocks. Whereas in October, 1917, stocks were from two to three weeks in Pennsylvania, Maryland, Virginia and West Virginia, on

Nov. 2, 1918, the range was from three weeks in western Maryland, Virginia and West Virginia, five weeks in western Pennsylvania, to seven weeks in eastern Maryland, nine weeks in eastern Pennsylvania and ten weeks in western New York state. Eastward, stocks were greater. Delaware had 13 weeks, New Jersey 12 weeks, southeastern New York State 12 weeks and northeastern New York 16 weeks. In the New England states stocks ranged from 19 weeks in Connecticut to 27 weeks in New Hampshire.

The lower peninsula of Michigan averaged 12 weeks' supply; western Ohio, nine weeks. The industrial section along the Arkansas River in Oklahoma and Arkansas had 10 weeks' supply; southern Florida, 12 weeks. The dock states had their supply assured and in the docks or in the storage piles of the plants. In the Missouri Valley section in Nebraska, Iowa and Kansas only were stocks below the general level of from six to seven weeks. The further from the sources of supply the larger the stocks—a normal and proper condition. Comparative data indicate that stocks of bituminous coal last November were from two to three times those of a year before, even on the basis of augmented rates of consumption.

What of 1919? Will the consumption of coal in the United States be as great in 1919 as in 1918? What, if any, effect will the impending release of centralized control and regulation of distribution, price and labor have on the ability of the coal mines to satisfy whatever the demand that may exist?

The consumption of coal in the United States will not be as great in 1919 as in 1918. The railroads, the largest single users of bituminous coal, will save coal if by no other means can their enormous fuel bill be reduced. A program for the conservation of engine fuel, begun by the Railroad Administration under Eugene McAuliffe, is now said to be conserving coal at the rate of 10,000,000 tons a year. Freedom to select the best and most suitable coals, a privilege largely denied during 1918, will reduce the quantity consumed.

Increased Demand from Industries

Manufacturing industry stopped overtime work in November; overtime operations that required coal. Not only was production of coal at a low ebb in December, but consumption declined and was in some districts below that in the hot months of last summer. However rapidly it may be accomplished, time is required for the transition from a war to a peace basis. The small-arms manufacturing plants are long on help and short on work. The airplane factories have largely ceased operation. The manufacture of smokeless powder is one item, the end of which releases around 4,000,000 tons of coal to other consumers.

The iron and steel industry has shown no indication of lessened requirements for coal, next year, and this is the most hopeful sign that has appeared. This industry, which reached its maximum speed under the conditions obtaining in 1918, consumes in round numbers one-third of the coal used by industrials and public utilities. A study of the reports of fuel consumption by 142 of the larger steel plants shows an increase of 18 per cent. in the average weekly consumption of steam and gas coal (exclusive of that used in making coke) in 1917 over 1916, and an increase of but 3 per cent. in 1918 over 1917. These plants had 54 per cent. more coal on hand Oct. 1, 1918, than on the same date in 1917.

By the summer of 1918 the United States had about reached the upper limit in ability to consume coal, and had the war progressed the ability to consume would have been reached long before the limit of ability to produce.

Conservation has affected and will continue to affect the consumption of coal, but even this praiseworthy doctrine has its backfires. Conservation of transportation exercised through the zones was responsible for making a contractor in Iowa use local coal, two tons of which was required to excavate the same quantity of earth for which but one ton of Illinois coal had previously been required. Many consumers not making ship plate, shells or high explosives found it necessary in 1918 to burn low-grade coal or none. They can now get high-grade coal and will need fewer tons.

Coal saved in 1918 through fear of shortage, and saved because not obtainable, will be coal burned in 1919. The consumer has been reached, however, with the message of true conservation—economy in use. More than ever will the vender of coal be preaching efficiency in use as a selling argument for his particular product. Waste and extravagance will not disappear over night, but the seed of the conservation idea has been intensively sown and the harvest will be greater in 1919 than in 1918.

Foreign Markets Prove Attractive

Eyes are being turned to foreign markets overseas. Exports offshore were 1,500,000 tons less in 1918 than in 1917, and 3,800,000 tons less than in 1916. An increase that will be measured in the millions of tons may be expected here, but to offset it will be a decrease of perhaps as much as 3,000,000 tons in coal for the navy. Bunker requirements will continue to increase with the growth of the merchant marine, but the total is not a significant item and affects but few producing fields.

Viewed in more detail, it appears that the New England and lake coal markets will be easily satisfied in 1919, excepting always the highest grades of coal for which the demand has not been fulfilled for several years. With the certain removal of all restriction in distribution and the adjustment of freight differentials disturbed by the flat 25 per cent. advance of June, 1918, the flow of coal will again turn westward, and West Virginia, Kentucky and Tennessee will compete with Illinois and Indiana, and Illinois and Indiana with Iowa, Missouri and Kansas. To what extent eastern coal will regain its western market is a question as yet unanswered. The time through which consumers were denied the high-grade fuel probably has not been sufficient to permit a proper appreciation of the advantage in use and cost of the local product. Anthracite and by-product coke will again enter largely in the market for domestic use. West of the Appalachians the maximum of production for several years was reached in 1918. The fields from Pennsylvania to Alabama can hardly as a whole expect to exceed the 1918 record in 1919, if in 1920, but the districts in that area from which come the highest-grade coals of the country will have every opportunity to prosper.

Viewed from a distance the progress of the coal industry has been continuously upward, but at close range

it is seen to have had many fluctuations. In the past 38 years, or since 1880, there have been seven "peaks" in the curve of bituminous production—in 1884, 1887, 1893, 1903, 1907, 1910 and 1913, with the expectation of the writer that 1918 represents the eighth peak. In the case of four of the seven depressions following these peaks, but one year was required for the "comeback"; but following 1884, 1907 and 1913, two years elapsed before new high records were established. The records for the past 18 years show but one instance where production was down for three years in succession. The record of 315,000,000 tons in 1873 was followed by three years of depression, and it was not until 1877 that production exceeded the output in 1873.

Activities of the Wholesale Coal Trade Association of New York

By CHARLES S. ALLEN
Secretary of the Wholesale Coal Trade Association of New York, Inc.

THERE is a feeling among the members of the Wholesale Coal Trade Association that there is a useful function to be performed by the organization, if for no other purpose than to cultivate a closer and more cordial relationship among those engaged in the wholesale coal trade. The Coal Exchange, one branch of activity of the association, while in effect but a few weeks, has resulted in bringing together the members in a number of trades, ranging in volume from a few cars to as many as 5000 tons in one transaction. These transactions, without exception, have been consummated between members who were not accustomed to dealing with each other, and the establishing of the Coal Excange has confirmed the judgment of the Board of Directors that it would act as a medium for broadening the field for all members making use of it.

It is the feeling of the members that every effort should be put forth to continue and extend the work of producing clean coal to take every possible precaution to maintain and improve the standard of Pennsylvania, West Virginia and Maryland coals, and it is felt that this work cannot be more effectively done than by a consistent program having this in mind and urged at all times by the wholesale coal dealers. A consistent policy of this sort can but prove beneficial not alone to the wholesaler, who will thus avoid complaints from his customers as to the quality of the coal, but will result in avoidance of the payment of high freight charges on refuse material and generally work a betterment of conditions for the operator by creating a firmer demand for his output, not to mention the economy of railroad facilities in times of car scarcity by avoiding the hauling of refuse matter. This consideration is of especial moment when taken with the effort which is to be made for a more scientific classification of coals in the pools of the Tidewater Coal Exchange.

Many of our members, in common with the trade generally, have suffered loss by reason of the changes made in assessing freight charges on coal moving through the pools in the early days of the Tidewater Coal Exchange, as well as those caused by the change in the rate.

The Association feels that this is a matter which should have vigorous handling looking to placing the work of adjustment where it belongs, certainly not upon the coalmen, and steps looking to this end are now in contemplation and will soon be put into effect.

Since the ruling of the Fuel Administration fixing the export and bunker margin of $1.35, members of the Association have had hundreds of thousands of tons handled through the agency of the United States Shipping Board, on a large part of which this margin has accrued; but as yet there has been no division of this fund among those interested. The Association purposes actively following up this matter with a view to effecting a distribution of the fund to those entitled to share in it.

The advantages to be gained by the extension of the system of trade acceptances in the coal trade generally are so great that the association will urge this matter strongly on its membership with the hope and expectation that it will be generally adopted.

With the beginning of the new year the gathering of information from members as to the standing of concerns with whom they do business will be taken up, and this information will be available to all members.

Occasion having presented itself for the taking up with the Barge Owners' Association of the matter of delays in the movement of barges by those who perform such service, other than the railroads, assurances have been given the representative of the association that the fullest and heartiest coöperation will be given to correct any such difficulties; and it is expected that when our members have troubles of this nature in the future they will be promptly remedied when handled through the secretary's office.

The coal trade has been so accustomed to sit silently by and permit to go unanswered the most vicious assaults upon its good name for business integrity, that it has now become the fashion among the muck-raking newspaper tribe to print anything that comes to hand, regardless of its relation to the truth. This has so long been the case that the public, in the absence of denials, has come to believe these libels. The officers and directors of the association feel that the time has come to make public refutation of these stories as they appear, and the endeavor will be to correctly inform the public on all such matters as they are brought up from time to time.

The ways in which this association can be of service to its members are almost limitless, and there is a most ardent determination with the membership, through the Board of Directors, to avail of those avenues of activity in the coming year.

Work of the Bureau of Mines During 1918

By VAN H. MANNING
Bureau of Mines, Washington, D. C.

A FEW illustrations of the work accomplished by the Bureau of Mines during the past year in connection with coal mining and fuel investigations are given in this article by Mr. Manning. The Bureau's most important duty was to add its small share toward aiding the country in winning the war. That these investigations were helpful and achieved their purpose have been evidenced by the numerous demands made upon the bureau and the comments of those who were in touch with its various work.

DURING the last fiscal year the Bureau of Mines devoted almost its entire efforts toward winning the war. An organization built up primarily for the greater safety of more than a million miners in the United States found upon the declaration of hostilities that it was thoroughly equipped by reason of its years of investigations to be of immediate assistance to both the army and the navy. Its experience with poisonous and explosive gases, such as are found in mines, suggested that its men might be helpful in developing the poisonous gases used in warfare. Its methods in first aid and resuscitation from the effects of mine gases were such that they could be applied in the medical corps of the army and were of great educational advantage to the fighting men as a whole. The sudden and tremendous demand for coal and the distressing experience of last winter, when the essential war-making factories were beginning to speed up in necessary supplies, indicated that the bureau's studies in the utilization of fuel with greater efficiency would come into important use. In fact, with the experience acquired, and its wide knowledge of mining, milling and metallurgical practice throughout the United States, the bureau was in a position to conduct many special investigations that had military importance and to cooperate with the various agencies that were participating in the great task of converting the country from one engaged in peaceful industry to one seeking to throw its overwhelming strength into the struggle for the preservation of democracy.

VAN H. MANNING

Perhaps the most notable work of the bureau during the war was its development of a great laboratory in Washington for the study of the gases used in warfare. The work the Bureau of Mines is doing on poisonous and explosive mine gases, the use of rescue apparatus and masks, the exploring of noxious atmospheres, and methods of resuscitating persons overcome by bad air had its beginning under the Government about ten years ago. Early in February, 1917, when war between the United States and the Central Powers seemed inevitable, the bureau called the attention of the War Department to the organization and facilities that the bureau already possessed for the study of poison gases, gas masks, etc., and offered these facilities to the War Department for such work. At a conference between representatives of the War College and of the Bureau of Mines, the War Department gladly accepted the offer of the bureau and agreed to support its work in every possible way.

The Director of the Bureau of Mines immediately started investigations of these war problems, and until July 1, 1917, carried the work along with bureau funds. The first work was on the development of gas masks. On July 1, 1917, the staff consisted of 50 paid investigators, and the work had expanded from gas mask research to the study of poison gases and other chemical products used in warfare. In order to enlist the cooperation of the universities and research institutions in the United States, personal visits were made to practically all of the important ones. The response was most gratifying, and some extremely valuable work has come from these universities and institutions.

This gas warfare work was started through the small nucleus of men who had been engaged in gas study in connection with the mines. Before it was finally turned over to the War Department at the close of the fiscal year, this laboratory had grown until it employed a force of 1700 chemists.

The Bureau of Mines can fairly claim that because it started this work on gas warfare and received the hearty support of the army and the navy departments, the National Research Council, state, educational and private institutions, the country is months ahead of where it would otherwise have been; American soldiers have had gas masks and gases with which to combat the enemy. Further, the developments in gas mask manufacture by the Surgeon General's office of the army, in gas manufacture and gas proving-ground tests by the Bureau of Ordnance, and the chemical warfare program of the navy, including the use of smoke screens, shells, toxic gases, etc., are results of this experimental work.

It is sufficient to say that through the energy of the research organization of the bureau the large-scale production of toxic gases was far ahead of the supply of shells.

As to the work done by the Bureau of Mines on the gases of warfare, the Advisory Chemical Board said officially: "The efficiency, success, fine spirit and enthusiasm under the leadership of the Bureau of Mines is a matter upon which we wish to congratulate the bureau, as well as upon the splendid group of unselfish, self-sacrificing men who carried on this arduous and dangerous work. The organization is complex and delicate, but well articulated and working with an efficiency and enthusiasm which have impressed us greatly."

It was soon learned that the engineer regiments, if they were to take part in tunneling work, would need the aid of an efficient mine rescue breathing apparatus. The bureau felt that the Gibbs apparatus, the develop-

ment of which had been in progress under its direction for several years, had been shown to be superior to similar devices for use by men entering poisonous or irrespirable gases. The use of the apparatus was recommended to the army for men engaged in sapping and mining operations. Since the Gibbs apparatus had not been manufactured commercially, contracts were entered into by the Engineering Corps of the army, with a certain manufacturing company of high standing, to furnish apparatus for the army and to the public under license from the Bureau of Mines.

At the request of the Ordnance Department explosives problems were undertaken. Many of these investigations were for the purpose of ascertaining the relative sensitiveness of explosives to frictional and direct impact.

DEMONSTRATING THE EFFECTIVENESS OF THE GIBBS BREATHING APPARATUS IN GASSY MINES

Many problems arose involving substitutes for the scarcer and more expensive constituents of industrial and military explosives. Because of the growing scarcity, through military requirements, of certain ingredients used in industrial explosives, it was thought wise to undertake the testing, for mine and quarry use, of a long-known but little tried explosive—liquid oxygen in a cartridge with carbonaceous matter, fired by ordinary caps or detonators. Results of tests in driving the Simplon Tunnel, in Switzerland, had been successful, but the explosive could not be obtained then at a price to compete with dynamite. However, the method was revived in Germany in 1914 soon after the war began, and in 1915, according to a German mining paper, was being used in three mines in Upper Silesia at costs per unit of coal blasted equal to that obtained with dynamite at 12, 13 and 15 cents per pound. American observers in Germany before the United States entered the war reported that liquid oxygen explosive was then being used extensively for general blasting.

To obtain information as to the strength of the liquid oxygen explosive and the best methods of use, a series of tests was made in the bureau's laboratory at Pittsburgh, carrying and soaking apparatus was made, and favorable tests were conducted in a quarry. Results showed that a mixture of liquid oxygen (85 per cent. oxygen) with carbonaceous and absorbent material was equivalent in strength to 40 per cent. dynamite. The chief difficulty in use is that the liquid oxygen evaporates so rapidly that the cartridge must be used immediately after dipping in the oxygen, hence further investigation is needed to determine the best way in which the explosive can be used practically in mines and quarries.

Work was also done and a report prepared on the use of stenches as a warning in mines. Electric gongs have been used as a means of signaling fires or other serious danger, but have not proved wholly satisfactory. Hence, the use of a stench in the compressed air delivered to all parts of a mine, where it would escape either from leaks or in the exhaust of machines, is offered as a substitute for the electric signals. The minimum concentration at which odors of a number of stenches could be detected in a current of moving air was determined in the laboratory, and the more promising stenches were tested at the experimental mine. The results ob-

tained indicated that this method of signaling will be of great value for warning miners and in future may be the means of saving many lives.

At the request of the War Department, the bureau conducted experiments with microphones and geophones, listening devices, which have been in use to a certain extent during the war to disclose the location of enemy artillery and to detect the presence of enemy mining operations. These investigations were so satisfactory that the bureau has determined to use these instruments in connection with rescue work. As these devices record air and earth waves, it is thought that they will be of value at mine explosions in determining the location of men who may be entombed and thus facilitate their recovery. The fuel problem was one of increasing importance as the war proceeded. During the summer and fall of 1917 the growing realization of a possible fuel shortage brought a large correspondence and many requests from the public for advice and for special direction in fuel problems. The need of more information written in a popular style on fuel subjects was partly met by new publications. In September representatives of the bureau took part in a speaking campaign through Tennessee, the object being to arouse the manufacturers of that state to a realization of the necessity of using coal more carefully.

TESTING LISTENING APPARATUS TO BE USED IN MINES TO LOCATE ENTOMBED MINERS

A considerable part of the time of the chief mechanical engineer was spent at Washington in conference with representatives of numerous organizations undertaking fuel propaganda. For a time it seemed as though too many organizations would undertake to advise the public on fuel problems, and it was feared that this advice would not be properly coördinated and hence would be apt to perpetuate many fallacies regarding the use of fuel. Many of these organizations were giving much heed to methods of presenting information and little thought to what was to be presented, assuming that essential information regarding methods of using different fuels with most efficiency could be obtained at any time.

In order to meet an evident need the bureau endeavored to act as a central source of technical information and to see that the matter being given to the public was not contradictory or inconsistent. Many manuscripts from all sorts of organizations were submitted to the bureau for technical criticism; they ranged from those suitable for publication as Government documents to those that were of temporary usefulness in newspapers and magazines.

In order that the bureau might better perform its function of advising Government organizations in fuel matters and do this in such a way as to command a wider support, an effort was made to obtain the advice and coöperation of the engineering societies, and the engineering council was asked to appoint a committee advisory to the Bureau of Mines. This committee later became a general committee on fuel conservation of the engineering council.

It soon became evident that of the many organizations desiring coöperative connection the United States Fuel Administration was the only one likely to persist. In the early period of building its organization, the United States Fuel Administration referred questions of economy in the use of fuel to the Bureau of Mines, and for some weeks a large correspondence addressed to the Fuel Administration was handled by the bureau. With the development of the conservation section of the Fuel Administration under its own engineers, the bureau continued its relations in an advisory capacity as fuel saving. The bureau also arranged for coöperation with the Society of Heating and Ventilating Engineers. The fuel division of the bureau was also called upon to assist the Emergency Fleet Corporation in the designing and baffling of boilers suitable for the new vessels. As a result of the investigation of one type of boiler used on a certain class of ships, the boilers were so changed that six tons of coal did the work formerly accomplished by seven tons. It is not unnatural to expect that the savings instituted will continue to bear fruit in the months to come.

Severance of Alsace-Lorraine Will Have Effect on Industry

The impending severance of Alsace and Lorraine from Germany, and their return to France, likely will have an important bearing on industry, as these provinces are rich in important minerals. The smelting of the iron ore production, especially of Lorraine, involves large quantities of coke. The old exchange arrangement between France and Germany, whereby German coke was supplied to France in return for ore supplied to Germany, will likely undergo important changes. The reason France smelted little of the ore from these provinces probably was due to shortage of fuel; large quantities of this ore were exported. In the future, trade arrangements will likely undergo radical changes and the coke necessary for the reduction of these ores may be shipped from England. Both France and Belgium's coal mines have suffered severely due to Germany's destructive policy, and a rationing of raw materials among the needy nations may be arranged by the more fortunate possessors of such supplies.

Anthracite Industry in 1918

By EDWARD W. PARKER
Director of the Anthracite Bureau of Information, Philadelphia, Penn.

IN SPITE of adverse conditions such as in no previous time in its history has beset the anthracite industry, the production of hard coal in 1918 was maintained to at least 99 per cent. of the maximum yield of the region, that of 1917. It is estimated by the Anthracite Bureau of Information that including the coal sold locally, the colliery consumption, and the output of the Bernice basin, the production of anthracite in 1918 amounted to 88,815,000 gross tons, as compared with 88,939,117 tons reported by the U. S. Geological Survey as the output in 1917. The first of the adverse conditions that affected the industry in 1918 was the almost continuous zero weather that, beginning early December, extended practically without interruption through January, February and March, seriously interfering with the operation of the breakers and with surface transportation. Notwithstanding the abnormal weather conditions, however, production during these three months was well maintained, February shipments making the second best record for that month in the history of anthracite mining, while March made the record for any month, with shipments amounting to a little over 7,275,000 tons.

E. W. Parker

Frozen switches, car wheels and water pipes, snow drifts and other troubles incident to the worst winter in the records of the weather bureau were overcome, for following the wage bonus granted by the supplementary agreement of November, 1917, the mine workers had determined to make 1918 the record year of anthracite production, and thus further increase their earnings. This determination was encouraged by mine operators, who in addition to spreading "win the war" propaganda among the mine workers, expended millions of dollars in mechanical equipment and labor-saving devices in order to increase production.

Shortage of Labor in Anthracite Mines

The record made in the first three months of the year, showing an increase of more than 600,000 tons over the same period of 1917, would have been maintained and the production for the year would have shown a gain over the preceding year of from 2,000,000 to 2,500,000 tons, had the labor situation remained normal. But army and navy enlistments and drafts, and the lure of high wages and easy terms of employment in shipyards and munition plants, particularly those working on the iniquitous "cost-plus" plan, wrought havoc to the labor supply of the anthracite mines, it being estimated that not less than 33,000 men left the mining regions during the spring and summer months.

Those that remained, however, true to their determination to make coal win the war, continued to maintain the production equal to, and in fact, slightly in excess, of the previous year, until October, when the spread of influenza in epidemic and virulent form so reduced the effective labor supply that production fell off sharply, the shipments in that month being 835,000 tons less than in the corresponding month of 1917. November shipments showed a further decrease of 1,268,654 tons as compared with November, 1917, so that not only was the gain made in the first months of the year wiped out, but a decrease set up in its stead. By December the effects of the influenza had about disappeared, and production was at approximately the same rate as in December, 1917. The shortage of labor and the epidemic were responsible for a loss in possible production to such an extent that an anticipated increase of approximately 2,500,000 tons, based on the record for the first three months of the year, was changed to a decrease of about 135,000 tons.

The production efficiency per man employed in 1918 was worthy of particular notice. The average number of men employed during the year probably did not exceed 155,000. In some months it was considerably below that figure. These 155,000 men produced 88,815,000 tons of anthracite.

Government Control of Coal Industry Beneficial

The year 1918 was unique in the annals of anthracite, as in bituminous coal mining, in that it was a full year of practically complete Governmental regulation of distribution and prices. In many respects this control was beneficial, and was particularly so as compared with the preceding twelve months. At the beginning of Governmental regulation in the summer of 1917, the public was led to believe that prices would probably be reduced, as a result of which many postponed laying in their winter's supply. Prices, however, were not reduced, but on the other hand, as a result of the wage advance in November, were increased 35c. a ton. The mistake of not purchasing in time was dearly paid for, as, due to the necessities created by the entrance of the United States into the world war, the demand for all kinds of fuel became acute; and in addition to this an unusually severe winter set in at an unusually early date, resulting in extraordinary demands for coal which the mines were unable to supply or the railroads to transport. Famine and panic conditions existed throughout the entire winter of 1917-18 and much inconvenience and some suffering resulted.

It is hardly necessary to discuss at length the "heatless Mondays" and other radical measures adopted last winter for the purpose of conserving fuel. It is worth mentioning, however, that probably the most salutary effect of the action of the Fuel Administration in this regard was bringing to the mind of the people a realization of the fact that the United States was actually at war, a fact that many did not at that time fully appreciate. It was one of the first lessons and a good one, and it laid the foundation for the plans of anthra-

cite and bituminous distribution in 1918 that have been carried out with signal success.

Early in the spring of 1918 the task of working out the problem of distribution was placed in the hands of a committee. The preliminary work of this committee was the obtaining from all anthracite producers and distributors a record of the tonnage conveyed to every community in the United States during the coal year from Apr. 1, 1916, to Mar. 31, 1917, and upon this record the basis of the proposed distribution for the coal year 1918-19 was worked out. It was quite evident from the start that some decided, not to say radical, readjustments in the disposition of the country's

ALLOTMENT OF DOMESTIC ANTHRACITE COAL YEAR 1918-19 COMPARED WITH DISTRIBUTION IN COAL YEAR 1916-17

fuel supply, both as to sections and uses, were necessary, and this was particularly true in regard to the prepared or domestic sizes of anthracite. It was not deemed necessary or advisable to place any regulations on the distribution of the steam sizes, except for some restrictions on the use of No. 1 buckwheat. This has become somewhat of a domestic fuel and its use as such is steadily increasing.

The plan of distribution of the domestic sizes as worked out by the committee and approved by Dr. Garfield, was announced in an address by Mr. Dickson, chairman of the committee, at a meeting of the National Coal Association in Philadelphia, May 29, 1918. It showed the necessity for material increases into the New England and Middle Atlantic states, in order to meet the needs of expanded population in those regions, due to the increased activities of war-materials plants, shipyards, etc. In order to provide for this, shipment of the domestic sizes of anthracite was prohibited into all states south of the Potomac and Ohio Rivers, with the exception of Virginia, and into all states west of the Mississippi, except North and South Dakota and Minnesota. The allotment to Virginia was materially reduced as compared with the shipments made to it in the basic year, shipments to the Central States were reduced by approximately 32 per cent., those to the Northwestern States by a little over 12 per cent., and to Canada by 6.6 per cent.

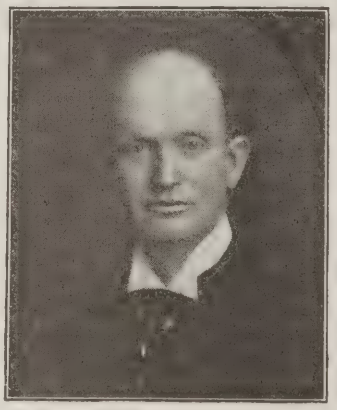
Subsequently the allotment to Virginia was increased by 65,000 tons, Iowa was given 145,000 tons to be distributed in the northern part of the state, and a small allotment was given to the northeastern section of West Virginia.

So efficiently has the committee carried out its program of distribution that the Northwestern states had received their full supplies before the close of lake navigation, New England in nine months had received nearly a ten-months' supply, and at the end of the calendar year coal was moving freely into those communities whose quotas had been held back somewhat in order to provide the Northwest and New England with fuel before winter weather prevented. The situation has been materially aided by the mild weather that has so far prevailed this winter and which has been in striking contrast to the winter of 1917-18. The new year opens with no reported suffering because of a shortage of anthracite, and with excellent promise of sufficient supplies and adequate transportation facilities to meet all current needs, a condition radically different from that of a year ago.

Public Wanted Any Kind of Coal

In January, 1918, the public was clamoring for any kind of coal; size made no difference and white ash was as good as red ash, and red ash as good as Lykens Valley; the cry was for "anything that was black." At this writing the consumer is demanding stove and nut almost exclusively, and stipulating the grade as well. It is quite evident to those familiar with the anthracite trade that had it not been for the effects of the influenza which curtailed production to the extent of approximately 2,500,000 tons, there would be more anthracite on the market today than it could readily absorb. Even now in many sections the steam sizes of anthracite coal are literally a drug on the market.

During the last two months of 1918, prices for anthracite have been higher than at any time since the Civil War. The advance in price, however, has not inured to the benefit of the operators, but has been absorbed entirely by the increase in wages given as a war bonus with the approval of the Fuel Administrator in November and made retroactive to Nov. 1. In fact, the returns on the capital invested in the anthracite industry have probably been less in 1918 than under normal conditions. It cannot be said that the Fuel Administration has been partial to the anthracite operators. Prices have been strictly held to the added cost of production in labor alone, without allowance for the increased cost of supplies, and other added expenses due to war conditions.



In November, 1917, when the second war bonus was granted, it was estimated that the average increased cost per ton would be 45c., and the Fuel Administration

was requested to allow that much to be added to the price. It permitted an advance of 35c., and although it was shown that the total average cost had been increased 78c., instead of 45c. following the November, 1917, wage increase, no allowance was made for it in adjusting the price following the new wage bonus in November, 1918, other than to permit the steam sizes to take the same advance as the domestic sizes. This was a questionable benefit, since at that time the steam sizes and become an oversupply and were being stocked in the storage yards of some of the larger companies. The industry absorbed the difference, and in addition assumed practically the entire cost of its own regulation by the Fuel Administration.

Readjustment Problems of the Coal Industry

By ERSKINE RAMSAY
Birmingham, Alabama

FORTUNATELY for mankind the work of making war is over and the reconversion of business to a normal basis should be done on some plan which will give the least possible shock to financial and industrial life. The transition from peace to war was quite painful, and unless the problems now confronting us are skillfully handled there is every reason to expect that the change back to peace will be equally as troublesome. The coal business is confronted with a serious situation; this comes from the fact that the coal operator during the war—from patriotic reasons, though knowing it was not good business—did his full duty and expended enormous sums of money in pushing development. Owing to this unusual development, made to win the war, the mine capacity is now far above the normal output of prewar times, and the capacity will further increase as the boys return home and resume their usual work. The present demand is not sufficient to take the output when running full. In the past such a situation always resulted disastrously for the operator. Before the war many mines were operated at a loss and unless prompt and effective steps are taken, this condition will return.

ERSKINE RAMSAY

It may be said that the public is not interested that any particular line of business should be operated without loss. With coal it is certainly different, as unprofitable mining with the necessity of low production costs and expenditures does not permit of the best methods of mine working being employed. Under such conditions necessary modern development and equipment required for economical mining and relatively complete recovery of coal cannot be provided. The more economically coal is mined and prepared, the cheaper the public will get its supply; as coal is one of the country's most valuable natural resources, conditions should be maintained which will insure the recovery of as near 100 per cent. of the coal as possible.

It is just as unfair to the country as a whole to permit coal to be sold at prices below the cost of production as it is for coal operators to take advantage of opportunities to make the consumer pay exorbitant rates; a way should be devised to avoid both such situations. We all remember how Mr. Peabody wisely started a scheme of voluntary price regulation, which work was later admirably carried on by Dr. Garfield, Director of the Fuel Administration, backed with full legal authority under the Lever Act. It will be a calamity to permit the abandonment of such war regulations before the signing of peace and before the National Coal Association, the United States Chamber of Commerce or some other competent agency works out an effective plan of regulation for submission to Congress, and which will insure stable prices and conditions, and friendly relations between business and government. The coal business has suffered greatly in the past by the railroads using their car supply as a bait for obtaining prices below the cost of production. In many cases the railroads have arbitrarily named prices and practically said "this or nothing"; when low prices were thus forced on the mines it went a long way toward pulling the prices on other things below cost.

The coal people of this country, in order to avoid wasting our coal deposits, must endeavor not to repeat the harmful practices of the past, which did great damage to both capital and labor.

The hundreds of thousands of men and women engaged during the war in making the many things required by the men at the front will now be compelled to secure other work. This readjustment of labor will necessarily call into play our greatest resourcefulness to successfully meet its difficulties and problems.

British Recapturing Business

BRITISH shipping interests are already making a great drive to recapture the ocean carrying trade which they were forced to relinquish during the war. According to information obtained recently in local shipping circles, British freight rates to South American ports have been reduced so heavily since the armistice was signed as to increase substantially the normal disparity between rates from Liverpool to South America and rates from New York to South America. As one instance it was stated by a member of a leading New York firm that the rate on general merchandise from Liverpool to Brazilian ports is now $10 a ton, or 66⅔ per cent. lower than the New York rate to the same ports, whereas before the war the difference was approximately $2 a ton, or 40 per cent. Advices received here are to the effect that the Liverpool rate to South American ports is around $15 a ton, against a range of $25 to $27.50 a ton for shipments from New York to the same ports.

Activities of the National Coal Association During 1918

A Resume of the Efforts Put Forth by the Association to Secure the Co-operation of the Bituminous Coal-Mining Industry with the Government in Its Prosecution of the War Program, and an Indication of What the Association's Work May Be in the Future

By J. D. A. MORROW
General Secretary, National Coal Association

A YEAR ago the National Coal Association was just getting under way in its effort to secure the fullest coöperation between the bituminous coal-mining industry and the government in the prosecution of the nation's war program. That effort occupied the attention of the association throughout practically the entire year. A brief review of what the organization accomplished in this respect is therefore quite appropriate. At this time also, with the association, the industry, and the nation facing the problems of peace and a world permanently changed in many ways, it is equally appropriate that we indicate briefly the direction which the association's work conceivably may take under these new conditions.

J. D. A. Morrow

A year ago the public had a right to expect that this industry would do its utmost to coöperate with the United States Fuel Administration, so that this nation and its allies might have the necessary quantity and quality of coal needed for the successful prosecution of the war. They also expected that this output would be placed in the hands of those who could use it most effectively for the same purpose.

The bituminous coal-mining industry has made good in meeting this expectation. It has produced a record tonnage estimated at 587,500,000 tons during the calendar year, more than 318,000,000 tons of which have been produced in the last six months of the year. Moreover, this tonnage has gone where the government wanted it to go, in full accordance with the plans of the Fuel Administration, the War Industries Board, the army and the navy.

The National Coal Association does not by any means claim all the credit for this memorable achievement. It has been the means, however, through which it was possible for Dr. Garfield at all times to keep not only fully in touch with the industry, but to have its thoroughgoing assistance and support. It was by utilizing in large degree existing machinery, built up by the constituent associations of the National, that the distribution plans of the Fuel Administration were carried out so successfully. Many of these local associations turned over their offices to the use of the Fuel Administration, including their secretaries, offices, employees and advisory committees. In brief, by utilizing these organizations in the industry, the Fuel Administration was able promptly to organize effective distribution machinery, relying throughout on the services of practical men who knew their own particular localities most intimately.

The record production of bituminous coal in this year was possible largely because the National Coal Association united all its energy with that of the Fuel Administration to remove every obstacle in the way of increased output, to increase the efficiency of the mine management, and to exert all pressure possible in order to produce coal. The result is historic. To me, it is just as remarkable a story as that of shipbuilding in the United States. Mr. Hurley and Mr. Schwab had a new industry to create. They were handicapped by many disadvantages and trials because it was new and had to be created from the ground up, but they also enjoyed the immense advantages of this same condition. They had every opportunity to revolutionize a little, mediocre, hand-to-mouth industry simply by applying the well-known principles of large scale manufacturing. That concept was one of striking genius, but the application of large-scale, standardized quantity production, not at all new in American business, produced miraculous results in a short space of time.

On the other hand, the bituminous coal-mining industry lost approximately 100,000 of its men to the army and still more to other industries; and with this reduction in its operating force it was called on to produce coal at the rate of 52,000,000 tons per month, which was 6,000,000 tons a month beyond the previous high record. Its task was to accomplish this result with 100,000 of its younger and finest employees absent from its ranks. Moreover, when this call came it was already a splendidly organized industry. The bituminous coal mines of the United States were by all means the finest in the world. They were better equipped with mechanical devices than any other. They were operated with all the practicable and tested advantages of American industrial achievement. This was a vastly different proposition from that of the Shipping Board. Beating the coal production record of 1917 was very much like asking a runner to beat a 10-sec. mark for 100 yards; the performance of the Shipping Board was much more like asking a trained sprinter to beat a 15-sec. record for the 100 yards.

Nevertheless, in the face of these conditions, which should be clearly understood to appreciate the magnificent response of the bituminous coal-mining industry to the nation's demand for coal, the production for the calendar year broke all previous records; from July 1 to Oct. 1, when peace negotiations and the influenza checked production, the output averaged approximately 55,000,000 tons a month, or at the rate of 660,000,000 tons a year. On Oct. 1, in spite of the handicaps of the beginning of the year, coal production was measurably up with war demand, and even had hostilities continued through the winter and requirements for coal for war needs continued as anticipated, everyone in Washington was confident that the bituminous mines would have produced the full tonnage asked of them before the coal year had ended.

There were moments, however, in the spring and summer when it seemed to be an open question whether the country would have as serious a shortage as last winter's or a more serious one. Every energy of the industry was then turned to maximum production. A census of bituminous mine employees was taken, revealing more than forty nationalities; an educational campaign was started in nine languages; and more than 12 tons of printed matter was distributed by the National Coal Association alone, through local associations and other agencies, to the miners. And the industry made good.

I dwell on this achievement of the bituminous coal-mining industry because we all take it too much as a matter of course. We are too accustomed to its tremendous achievements year by year to weigh properly such a record as it has made during 1918. It is the kind of thing that Lowell meant when he spoke of the "miracles of the commonplace." As this article is being written the directors in a meeting, at which prominent operators from all parts of the country will be present, are working out general plans for the activities of the Association under the conditions of reconstruction and peace. The task here is to make sure that the industry is amply equipped with the information and legitimate assistance that it may derive from a national federation of local associations, in such an organization as the National Coal Association.

NOT only has the National Coal Association assisted the soft coal industry during the last year in a truly remarkable fashion, but it has awakened the industry to a new sense of its dignity and power. For the first time the bituminous coal operators now have a national viewpoint and a national organization that has made itself known and respected throughout the nation. It has been the means of gaining for the industry a public recognition that was never accorded to it before. With a successful working out of the many plans now receiving the attention of the members of the association will come a finer spirit among the operators themselves.

In years gone by, one of the chief weaknesses of the industry was its lack of accurate information concerning market conditions. Hundreds of bituminous coal operators were strikingly ignorant of costs, selling prices, stocks and other market conditions. In consequence, they and the industry were at the mercy of rumors, uncertainties and deliberate falsehoods. Other leading industries of the nation, however, had made it their business to equip themselves thoroughly with the fullest kind of information that affected the production and marketing of their products. The individual member of these industries therefore was able to decide his production and marketing policies intelligently, and on the basis of definite facts and figures. On the other hand, the bituminous coal operator all too often decided his production plans and marketing policies on incomplete or incorrect information. To remedy this former weakness of the industry is a great undertaking, but it will receive the fullest consideration of the board; if it seems practicable some action will be taken to give the members of the National Coal Association and its constituent local associations the fullest possible information regarding market conditions.

A thoroughgoing knowledge of costs is recognized as the foundation of conservative conduct of any business. In this respect also the coal industry in years gone by his been wofully lacking. Such information is of equal importance with facts concerning market conditions. The National Coal Association has recently organized a Cost Accounting Department which is working in conjunction with a Cost Accounting Committee (of which T. T. Brewster, of St. Louis, is chairman) in an effort to devise with the help of the industry, the Treasury Department and the Federal Trade Commission a thoroughly sound and acceptable definition and classification of costs which may become the basis for uniform cost accounting in the industry.

If such a system can be worked out and established, it will save both the operators and the government much inconvenience and expense in making reports to Federal agencies, and it will also educate hundreds of operators to a better understanding of their production and marketing costs that they ever have had before. If such information, combined with the facts regarding marketing conditions, can be put generally in the hands of the industry through the medium of the National Coal Association and local organizations, bituminous coal operators will compete with each other for the first time in the United States on a basis of intelligence instead of ignorance. The future work of the association, therefore, lies along constructive lines for the permanent lifting of the industry onto a new plane of participation in American business. It means a coöperation with a half-dozen departments of the government. It means better coöperation through the industry. It implies a finer spirit among the operators themselves and it means a great deal of detail work to carry these efforts to successful realization. In the past year, the association has made a record of which it may well be proud, but its real work is only starting.

[As this issue of *Coal Age* goes to press reports come to hand of the meeting of the National Coal Association at Washington, at which bituminous operators from every section of the country took steps to place on foot the plans referred to by Mr. Morrow in the foregoing article.—Editor.]

Coal-Mine Fatalities in 1918*

By ALBERT H. FAY
Mining Engineer, Bureau of Mines, Washington, D. C.

PRELIMINARY reports received from the state mine inspectors for the first eleven months of 1918 show a reduction of about 7½ per cent. in the total number of fatalities in the coal mines as compared with a like period for 1917. The total number of fatalities reported to the Bureau of Mines to the close of November is 2281 in 1918, as compared with 2471 in 1917. The principal decrease is in gas and coal-dust explosions. In these two items alone there is a reduction of 211 fatalities. There is also a reduction of 25 fatalities due to mine cars and locomotives, and a slight reduction due to hoists, cages and skips. A slight increase is shown in fatalities due to falling coal or rock, the use of explosives and electricity. With no serious disasters for the month of December, the net decrease for the year should be about 190, as indicated in the accompanying table.

ALBERT H. FAY

Complete figures for the number of men employed during 1918 are not yet available, but on account of war conditions the number undoubtedly will be less than in 1917, when there were 757,317 men engaged in coal mining. The number of days worked during the year will be in excess of previous years, and the tonnage won will tend to offset shortage of labor. In 1915 the average number of days active were 209; in 1916, 235; and in 1917, 251.

Concerning 76 of the 112 fatalities due to mine explosions, sufficient information was obtained to show that 51 per cent. were due to explosions caused by open lights and 37 per cent. were due to shots. The electric arc was responsible for about 6 per cent. This emphasizes the need of abolishing the open light in all doubtful mines, more care in the use of explosives and more thorough inspection and installation of electric lines.

In 1918 there were reported only three mine explosions and one mine fire, in each of which more than five men were killed, representing a total of 52 fatalities as compared with eight similar disasters in 1917 resulting in 256 fatalities. This indicates a considerable advance in the use of safety devices and appliances for the prevention of mine explosions.

FATALITIES DUE TO GAS AND COAL-DUST EXPLOSIONS

Cause	Number Killed	Per Cent.
Due to open light	39	51.3
Due to defective safety lamps	2	2.6
Due to electric arc	5	6.6
Due to shot	28	36.9
Due to explosions of powder	2	2.6
Total	76	100.0

A chronology of these accidents and their results is as follows: May 20, Villa mine, Charleston, W. Va., mine fire, 13 killed; Aug. 7, Harmar mine, Harmarville, Penn., explosion, 5 killed; Aug. 28, Burnett mine, Burnett, Wash., explosion, 12 killed; Sept. 28, North mine, Royalton, Ill., explosion, 22 killed. Fatalities due to electricity at coal mines increased 13 during the year, or about 15 per cent. Forty-six of the 87 fatalities may be segregated as indicated in the accompanying table, in which 28, or 61 per cent., were due to coming in direct contact with the trolley wire; 11, or 23.9 per cent., were due to contact with mining machines, while feed wires were responsible for 10 per cent. Fatalities such as these call for better installation of trolley wires, locating them out of reach of workmen, or, when this is not practicable, guards should be provided that will make it almost impossible for one to come in contact with the live wire. Electric haulage roads should not be used as manways where it is possible to travel along other entrances and exits. Mining machines and machine feed wires should be inspected frequently to see that the insulation is in perfect condition.

FATALITIES DUE TO ELECTRICITY

Cause	Number Killed	Per Cent.
Direct contact with trolley wire	28	60.9
Bar or tool striking trolley wire	2	4.4
Contact with mining machines	11	23.9
Contact with machine feed wire	5	10.7
Total	46	99.9

Accidents Due to Cars and Motors

Of the 431 fatalities due to mine cars and locomotives, the inspectors' reports covering 229 of them show

COAL-MINE FATALITIES FOR THE FIRST ELEVEN MONTHS OF 1918, COMPARED WITH THE SAME MONTHS OF 1917

Underground	January-November, 1917	January-November, 1918	Increase or Decrease
Falls of roof (coal, rock, etc.)	1,066	1,008	+21
Falls of face or piller coal	68	147	
Mine cars and locomotives	440	431	—9
Gas explosions and burning gas	172	73	—99
Coal-dust explosions (including gas and dust combined)	151	39	—112
Explosives	10	110	+9
Suffocation from mine gases	12	15	+3
Electricity (shock or burns)	74	87	+13
Animals	10	6	—4
Mining machines	16	18	+2
Mine fires (burned, suffocated, etc.)	2	18	+16
Other causes	70	53	—17
Total underground	2,182	2,005	—177
Shaft			
Falling down shafts or slopes	23	24	+1
Objects falling down shafts or slopes	5	9	+4
Cages or skips	16	9	—7
Other causes	4	3	—1
Total shaft	48	45	—3
Surface			
Mine cars and mine locomotives	86	70	—16
Electricity (shock or burns)	16	17	+1
Machinery	43	38	—5
Boiler explosions or bursting steam pipes	6	6	0
Railway cars and locomotives	16	23	+7
Other causes	74	77	+3
Total surface	241	231	—10
Grand total	2,471	2,281	—190

*By permission of the Director of the Bureau of Mines

sufficient details to make the following classification possible:

FATALITIES DUE TO MINE CARS AND LOCOMOTIVES

Cause	Number Killed	Per Cent.
Switching and spragging	3	1.3
Coupling cars	8	3.5
Falling from trips	27	11.8
Run over by car or motor	97	42.4
Caught between car and rib	48	20.9
Caught between car and roof while riding	9	3.9
Runaway car or trip	37	16.2
Total	229	100.0

It will be noticed that fatalities while riding on cars are still common, the number of deaths by falling from trips being 27, and those due to being caught between car and roof while riding being 9, or about 15 per cent. of the haulage accidents. Accidents while riding can be reduced by enforcing more strict regulations with reference to riding on the cars.

Another important item under haulage accidents are fatalities due to being caught between the car and rib, representing about 21 per cent. These can be reduced by widening the haulageways, or by cutting additional safety niches, at intervals of 50 to 100 ft., where it is not practicable to widen the entire haulageway. The figures in the table show that 16 per cent. of the haulage fatilities are due to runaway cars or trips. There is therefore still room for mechanical improvement to prevent such accidents.

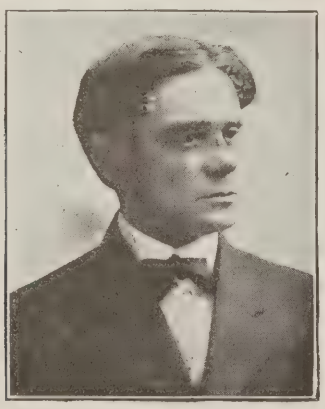
FATALITIES DUE TO EXPLOSIVES

Cause	Number Killed	Per Cent.
Transportation of explosives	8	15.1
Charging	4	7.5
Suffocation	3	5.6
Drilling into old holes	2	3.8
Caps, detonators, etc	1	1.9
Returned too soon	13	24.6
Premature shot	6	11.2
Sparks from match, lamp, or candle	7	13.2
Delayed blast	2	3.8
Shot breaking through rib or pillar	7	13.2
Total	53	99.9

The total number of fatalities arising from explosives was 110, showing a slight increase over the previous year. Of this number 53 may be segregated as indicated in the table shown above.

The Business Outlook in America

By Charles S. Keith



President Central Coal and Coke Co., Kansas City, Mo.

I BELIEVE the United States is in for several years of prosperous conditions. Here are the facts upon which I predicate such a conclusion:

1. Europe's supply of raw material, which she does not herself produce, has been depleted.

2. Farm products in the United States have been at a high price since 1914 and our farmers never were more prosperous.

3. Due to the price of wheat having been guaranteed for next year, and the world's shortage of fat, the prices of farm products will remain at a high level during 1919.

Charles S. Keith

4. Because of the immense shortage of shipping, Europe will purchase her supplies from the nearest sources of production. A ship can make three round trips between New York and Liverpool in the time required for one trip to Australia.

5. The United States is the only country financially able to assist the nations of Europe in their work of reconstruction and replenishment.

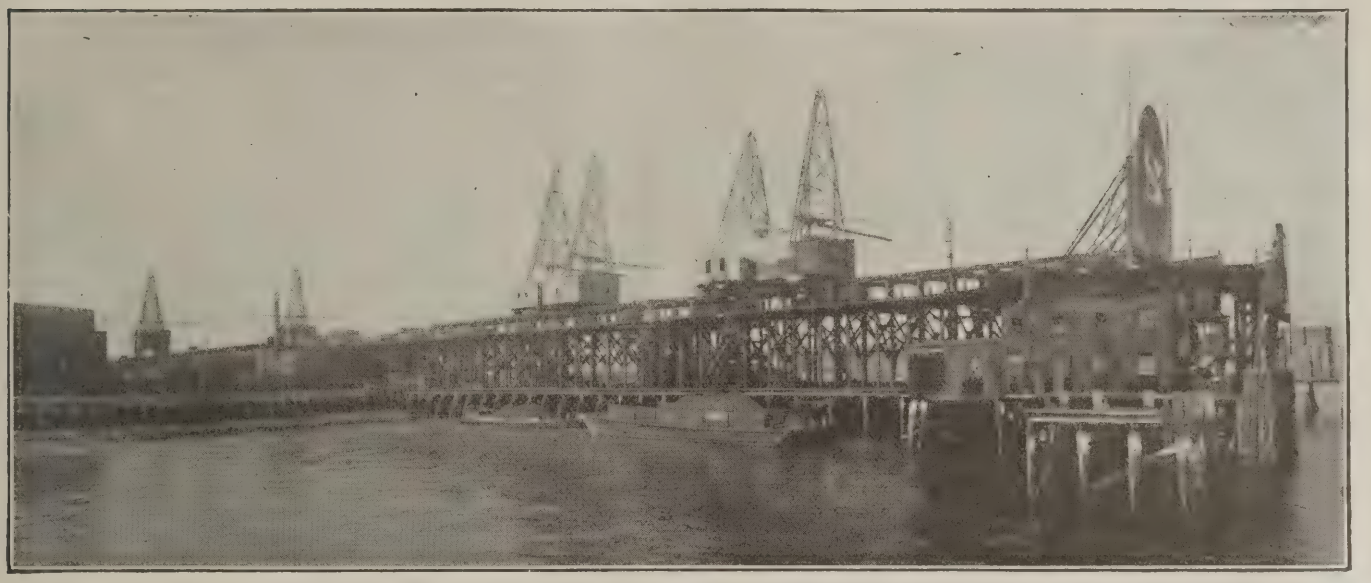
6. In the United States today the delayed building amounts to more than $3,000,000,000.

7. As each month passes more ships will be released from the work of transporting troops from France.

8. The present stocks of practically all commodities are low. In the matter of lumber only 46 per cent. of the normal supply remains at the mills, and but 75 per cent. of the normal supply remains in the hands of retailers.

In the face of such truths it is not logical to conclude that business is going to be poor.

Pulverized Coal for Metallurgical Use Should Possess Little Sulphur



Pulverized coal for metallurgical use should have a low percentage of sulphur, for the sulphur of the coal has a remarkable way, especially in the open-hearth furnace, of entering into the finished product. The ash in anthracite, coke breeze and lignite, speaking generally, will slag at the same temperature as the ash in bituminous coal. Therefore, the furnace temperatures may rise higher than the fusing temperature of the ash in the fuel.

The reason why the fusing temperature of these fuels is not so important as the fusing temperature of bituminous coal is because, in general, the combustion of the other fuels when they have been pulverized does not produce so high a temperature as does pulverized bituminous coal. In a well-designed furnace, temperatures about 2250 deg. F. (1235 deg. C.) will be obtained with anthracite, coke breeze and lignite, and slags will be formed.

Much emphasis has been laid on burning all the coal to carbon dioxide. To do this a higher temperature is sought by diminishing the amount of excess air. But these high temperatures cause ash, slag and clinker to form on the tubes, checker work and furnace walls, and this is detrimental—*A. V. Adamson, Bulletin, American Institute of Mining Engineers.*

Trade Conditions in New England in 1918

By G. G. WOLKINS
Boston, Mass.

LIGHTERAGE PLANT OF THE METROPOLITAN COAL CO., SOUTH BOSTON, MASS.

THE distributing factors showed a splendid spirit of coöperation throughout 1918. The Fuel Administration had complete charge of the industry, but the trade loyally responded to every appeal, and there was gradually built up an understanding of ways and means that led to the heaviest tonnage New England has ever known.

The first half year there were grave doubts whether this territory could possibly get its quota. A breakdown was feared, and more than once the strong arm of the Government had to strike a balance; but in review 1918 will stand out distinctly as a year of maximum effort. The bill came high, but never was railroad service so adequate; never were so many ships; and never was so great a reserve piled up. In the light of balanced production New England industries were indispensable, and it was due to the remarkable teamwork of patriotic and capable men that this fact was recognized at Washington.

General Features

Confining our review to New England, there were situations and developments peculiar to the Northeast that ought surely to be included. To go beyond the intense cold that closed harbors and paralyzed train movement for days at a time, there was evolved the famous New England priority order of Jan. 3, designed to furnish an ample and continuing supply of emergency coal for distribution east of the New England gateways. Diversion of 1000- and 1500-car lots had already been accomplished en route to the Shippensburg bottle-neck, and to provide billing, etc., a unique system was devised. The New England wholesalers, all of whom were being regularly deprived of coal through intervening mandates of the fuel authorities, were invited to finance the whole arrangement, taking for their services, the credit risk, and mental suffering, a special indulgence of 15c. A staff was organized, something like 2,000,000 tons all told was handled, and now, a year later, the device is still in operation, for the straightening of accounts. Invoices were "allocated" as nearly as possible on an equitable basis; the merchant or "jobber" paid promptly and then looked to the consignee in each case for reimbursement. The scheme had many merits, not least among them the active interest it roused among trade veterans who might otherwise have sulked in their tents.

Another feature was the broadminded way in which distribution was effected, often without too much regard for decrees at Washington. Centers of population were not put out of business because their supporting industries happened for a time not to be on a "Preference No. 1 List," and good sense was shown in not interfering more than seemed necessary with the normal trade channels of supply. Early in January Boston was down to four days' reserve, and distracted retailers in several instances closed their doors to protect their property from angry householders. Distress was frequently averted by refraining from the wholesale diversions practiced in other sections. There was a weighing and balancing of the claims of different communities, a process in which experienced coal men were

in position to advise, and there was a general absence of that panicky disposition which could only have been disastrous. Coal was taken out of schoolhouses only when hospitals and families needed instant relief, and coal was withheld from important industries only when pumping stations and other vital necessities were operating on margins too narrow for the public security.

The bulk of the tonnage came through normal channels, much as usual, but a great deal more than the excess over 1917 was supplied as "emergency fuel." The increase from central Pennsylvania only made up for the zoning away of Pittsburgh output and the reduced volume from adjoining districts. The heavy movement over Baltimore piers during July, August and September was intended to replace coal usually furnished all-rail or transshipped at New York, as well as yield a part of that additional supply demanded for New England's absolute needs. The greater proportion of this emergency coal was furnished through the Shipping Board and other Government pool accounts at Hampton Roads, but in most cases after April and May it was shipped and invoiced by the usual trade agencies. Several of these shippers very largely increased their tonnage, while all-rail practically every New England house in the business showed a heavy shrinkage, after vicissitudes that for weeks at a stretch left the middleman high in the air. Many of the all-rail houses rebilled coal at invoice to themselves purely to hold customers in line, the fuel regulations having come in to prevent more than 15c. as compensation for a service often divided between two selling organizations.

The authority given fuel officials to requisition coal, a power often used only with regard to some specific case at that moment in view, resulted too frequently in disrupting normal, well-matured plans of distribution, and early in the year there was a marked tendency toward "emergency orders all-rail," much the less expensive route. When serious demurrage charges began to accrue on waterborne coal from Hampton Roads, the differential was in some instances $3, $4 and sometimes $5 per ton, but those New England consumers elected to pay the freight took their medicine rather more cheerfully than might have been expected.

In 1918 there were two well-defined periods, of six months each. In the first there was great anxiety lest the supply be interrupted. To get coal every expedient was tried. In May alone, notwithstanding the most binding of promises, the total loss was 530,308 net tons, as compared with May, 1917, an alarming figure when all estimates had been based upon heavy gains during the summer months. Ships were not to be had in sufficient number; submarine ventures were threatening; all the early programs fell short of being practical; there was wavering between state administrators and Washington as to what were to be made special cases, and what were to be left to individual action and to chance.

Receipts were steadily falling behind; there was need of cloth for uniforms, need for surgical dressings, shoes, gas masks, need for innumerable supplies to be had almost exclusively from this territory; and not until labor organizations and manufacturers' committees joined in shouting "No coal, no supplies," did there seem to be any effective response. At last, in July, ships appeared as out of the night, and coal in great junks, both by rail and by water, began literally to be thrown at New England. It was as if every unheard petition of months was suddenly answered, and in good measure, full up and brimming over. Enterprising industrials had used every means at command to get coal, and, as it seemed, every forlorn hope was now being made good. There is credit due the New England Fuel Administrator for perseverance during a trying season, but it should be remembered that among his associates in the Massachusetts Committee of Public Safety were gentlemen of far-reaching influence, who were able at the appropriate hour to turn the right key. And there came a time in September, when it took almost the same tremendous effort to get it stopped! For several weeks there was no Gargantua to turn off the spigot!

On Oct. 1 the official report charged Massachusetts with 19 weeks' supply, greater than any state but Minnesota. New England was plugged full; and for trade or market the balance of the year was nothing to talk about. Everything together, it is quite within bounds to add that never in twelve short months were there both famine and feast the equal of 1918.

In New England, as elsewhere, the mid-year change of outlook was due more than anything else to the great gain in car movement. The effective pooling of equipment made it possible to pass unbroken trains through the New England gateways. Thus the roads gave better service.

* Courtesy of the Boston Chamber of Commerce, Statistics Department. † Almost exclusively from Louisburg, Cape Breton, except during 1903, when a large tonnage came from Great Britain to relieve shortage because of strike. ‡ Includes one cargo, 5,860 tons, from Charleston, S. C.

than consignees had ever known. The quota of 1,000,000 net tons monthly, Apr. 1 to Oct. 1, was exceeded, and yet in June, following the two heaviest months, it was officially stated by representatives of the Boston & Maine, the Boston & Albany, and the New Haven, that, based upon movement at that time through the western gateways to New England, there could have been handled an additional quantity of all-rail coal into New England of 450 cars per day. Certainly this is eloquent of enlarged capacity on the part of roads that too often have found themselves overburdened.

That was precisely the case in January-February, 1918. Congestion at Maybrook, N. Y., one of the five gateways, was unparalleled; 4000 loaded coal cars were backed up beyond, and congestion in several of the mining districts was something tremendous. Divisions normally moving 2000 loaded coal cars daily had 10,000 on tracks, and the average haul per day was down to 12 and 14 miles. The loss of car service through extreme cold and the comprehensive diversion to tidewater of coal originally routed all-rail seemed to make it clearly impossible in February to get adequate shipments, even in what had always been considered rail territory. It was also made clear that requirements in New England were increasingly dependent upon ships. It was taking six weeks for cars to come through to points like Worcester, Mass., and this fact together with the long hauls to remote destinations had a distinct bearing on the number of cars forwarded.

The Railroad Administration order of Jan. 3 requiring cars to be placed at designated mines in addition to the usual distributive share of the general car supply was a well conceived attempt to meet the emergency needs of a large number of important steam users in distress for dependable supply. Coal emanating on the Western Maryland and on the Baltimore & Ohio on a program of 200,000 tons annually was eliminated in June from all-rail movement upon the understanding it would reach New England by water through Baltimore and New York piers, a restriction that was not lifted until Dec. 20. In April the New England railroads were sending empties to the mines in an effort to build up fuel reserves, but apparently there was only one result—car shortage at the rehandling wharves at this end.

By May there was wonderful improvement. All operating embargoes against New England roads had been raised, and cars were coming through in eight or nine days to points like Worcester. Manifestly, congestion was being cleared up for the season, and yet so strong is the habitual cast of thought that there was

constant talk throughout the spring and summer of "zoning" consuming territory as between rail and water deliveries. Much hard work was put into this proposal. A hearing was held in Boston on June 4 by representatives of the Railroad Administration, and various opinions sought as to where the eastbound limits of all-rail bituminous should be drawn when congestion via the Hudson River gateways should become so great as to relieve them by diversion to water routes. It was plainly stated that the meeting was for the purpose of drawing the line in advance of the time of need and the Car Service Section gave assurances there would be no difficulty in providing cars, the saving of car miles in this case being unimportant.

There was one point in the discussion, however, that might have been of revolutionary importance. By railroad men present it was stated "that shippers forwarding coal all-rail should be ordered to ship their coal to the same consignees by tidewater, or possibly to ship it to other consignees in the all-rail zone in New England, so that New England would not lose the coal"! In a measure this was carried through when Somerset, Upper Potomac and Fairmont outputs were zoned out, but the aggregate tonnage affected was relatively small and confined very largely to points within Connecticut. To have enforced such a limitation on coal from central Pennsylvania, tidewater handling facilities considered, would have raised hob with conditions. The marvel is that such a fallacy persisted so long, and the trade is fortunate there was enough good sense at Washington not to put it through. A similar attitude prevailed when most extraordinary and expensive efforts were made to get cars unloaded with lightning dispatch, while at the same time empties were stored for weeks on New England lines because the connecting roads could not take them away. Since June the mining regions most accessible to this territory have been glutted with cars.

VIEWS AT THE WHARF OF THE BURTON-FURBER COAL CO., EAST BOSTON, MASS.

The best opinion inclines to present methods of distribution, unrestricted as to destination, whether from gateways or from tidewater ports. The fact that the nearly 12,000,000 net tons received last year went to make up deficiencies by water should be reason enough for allowing coal to come through normal channels. The anxiety of operators during June and July over possible congestion at the gateways was not borne out. Everything was comfortably handled. Not one coal embargo was in effect on New England roads from Apr. 1, and the fact that rail movement decreased during the fall was due first to a saturated market and later to very largely diminished output at the mines. Certain statistical reports intimating 50 to 60 per cent. car supply in central Pennsylvania were based upon archaic car allotments, based not upon normal output but on 100 per cent. effective—that is, a mine-worker in every place the full working day. Such a Utopian state never existed!

Water transportation was similarly the cause of much anxiety. In March the situation in that respect was thoroughly canvassed by the Shipping Board and the conclusion was reached that from April to December inclusive to move the 16,000,000 net tons at that time estimated to be required from Hampton Roads and Baltimore the shortage of steam tonnage was something like 170,500 D. W. tons. The tonnage then in service was an uncertain quantity. Much of it was assigned for temporary use and was subject to withdrawal. Many of the bottoms in service were Dutch, Norwegian or other neutral ships, almost impossible to discharge without maximum expensive delays, and rehandlers had a most uncomfortable time of it. Gradually, month by month, the available supply was augmented by new lake-built craft and by additions like the "Tuckahoe," until in July all fears for scarcity of tonnage had been dissipated.

At weekly meetings with an advisory committee of coal shippers, all of them experienced and conversant with every phase of the coastwise situation, a representative of the Shipping Board acting in conference also with the New England Fuel Administrator assigned steamers for charter; and in these friendly gatherings organized to make the best possible use of cargo space and available coal the steps were taken which effectively distributed the bulk of water-borne coal during the crucial months last spring when too many mistakes might have spelled calamity. The arrangement was faithfully carried out to the end of the year. In September, when instead of 238,000 tons the steamer tonnage aggregated more than 400,000 tons, the shippers made just as loyal exertion to keep them in operation as in the spring they had made to place each ship where its cargo would do the most good.

Rail Receipts—Domestic sizes eliminated on following percentage basis as determined by reports received from agents at gateways: 1918, April, 74 per cent., May, 73 per cent.; June, 75 per cent.; July, 73 per cent.; August, 73 per cent.; September, 78 per cent.; October, 84 per cent.; 1917, April, May, June, July August, September, October, each estimated to be 90 per cent.

Tide Receipts—Domestic sizes eliminated as follows: Both coal years, April, 89 per cent.; May, 89 per cent.; June, 89 per cent.; July, 86 per cent.; August, 85 per cent.; September, 94 per cent.; October, 93 per cent. Basis of elimination was the record of anthracite dumpings at New York, divided into domestic and steam sizes, beginning June, 1918.

The disparity in rates between all-rail and the water routes was never so glaring. Until June 25, rail tolls had been advanced only 15c. in ten years. The minimum rate from central Pennsylvania to Boston, for instance, was $2.60 (now $3.30) "to meet tide-water competition" when water freights were 50c.@75c. from Hampton Roads, and not $3.25, as in 1918. Output from West Virginia today has to stand $2 tolls plus $3.25 marine freight, and from central Pennsylvania via New York $2.15 tolls plus $2.50 marine freight, other charges applying in each case. The sum of tolls, water freight, and charges in each case compares with the $3.30 rate all-rail. The outlook for coal in 1919 turns very largely on the manner in which the differential is handled. Apparently it is up to the Shipping Board. They have withdrawn ships, but rates have not been modified.

Pocahontas and New River Grades

Based upon the expansion in war industries and depleted reserve stocks, representatives of the Fuel Administration and the Shipping Board estimated in March that New England would require an increase of 15 per cent. over receipts in 1917, rather than the 30 per cent. mark previously set by the New England Fuel Administrator. The 15 per cent. figure meant that of the 30,000,000 net tons for the coal year, 16,000,000 would be required from Baltimore and Hampton Roads, the increase from these ports alone being figured at 6,500,000. The heavy movement of water coal was to be developed during the months from April to October, to allow for light movement the remaining months, but of course anything like this schedule was not reached. It was far in advance of what representative shippers could imagine as a probability, and the event justified their opinion. The Fuel Administration provided that a large share of West Virginia output, particularly from the smokeless districts, should be held for tidewater movement, and with some shuttling to take care of byproduct plants like the Hopewell powder plant, this part of the program was reasonably well adhered to.

The price disparity of 35c. between Pocahontas and New River was a notable feature of 1918. Until the latter part of 1917 the two coals were on the same basis,

and also closely competitive. Had price been any consideration the ruling would certainly have upset selling arrangements of long standing and caused no end of confusion. As it was, consignees took either coal so long as bottoms could be found to move it and so long as there was room for it in storage.

The smokeless shippers never enjoyed a more lucrative year. Compensation was liberal, if not lavish; and coal was shipped in record volume.

High Volatiles

Throughout the year there was difficulty getting the higher grades for illuminating, byproduct and malleable iron purposes. A large number of New England plants had their source of supply in the Pittsburgh and adjoining districts, and in the Fairmont region. To all practical purposes these coals were excluded from this territory. Fairmont was allowed to come through the Tidewater Coal Exchange, but gas-coal consumers are never partial to "low-sulphur screened" coal that comes through a pool. There was an indifferent effort to reduce the tonnage of highest grade gas coals appropriated for railroad use in fast-train service, but very little came of it. One road alone in New England uses 150,000 for this purpose.

As an emergency measure in July 200 cars daily were ordered out of westbound shipments from the Kanawha

and other high-volatile sections on the Chesapeake & Ohio Ry. This was not so much a help to plants requiring illuminating or long-flame coals, for it was open to the same objections that apply on any coal pooled at Tidewater. Gas plants took more or less of this tonnage to make up arrears all-rail, but the bulk of it was delivered to steam plants on contracts originally written for Pocahontas or New River. The same circumstances were true of a large extra tonnage of Fairmont, Pool 34, moved via Baltimore piers.

The Westmoreland district was so heavily burdened with special orders for steel plants and the like that hardly better than 65 per cent. was averaged on contracts entered into with New England buyers. Consumption here, however, is now reduced and there is prospect that the remainder of the winter will find gas-coal requirements in much more comfortable shape than was feared.

Georges Creek

The tonnage of this once popular grade was practically nil in New England during 1918. Several thousand tons were caught in the Shippensburg diversion late in December, 1917, and the principal shippers responded to the New England order of Jan. 3, but thereafter deliveries were of no moment. The bulk of the coal, in Pool 1, at Baltimore, went either for export or for naval use. The fixed price for that region was not favorable to large output, and transportation ordinarily reserved for the movement coastwise of Georges Creek was diverted, often by order of the Fuel Administration, to load at Hampton Roads to help make up the deficiency there in cargo space the first half year. The large increase in receipts here from the Baltimore piers was due to Fairmont and other coals on the Baltimore & Ohio and Western Maryland thrown to Tidewater rather than all-rail. It is probable that in future Georges Creek in this market will disappear from the steam trade and be confined to smithing purposes.

Pennsylvania Grades

Central Pennsylvania was New England's most dependable source of supply during the lean season from January to June, 1918. It was the source of most of the coal shipped on the "New England order," the channel through which most of the emergency fuel came the first part of the year. As drawn at Washington the order called for 500 cars daily, and direct consignments for that number were furnished by the New England Fuel Administration; but on only one day did the actual yield exceed 300 cars, and the average for the 100 working days it was effective was little over 100 cars. That meant 500,000 tons, however, and in January, in particular, it averted what might have been some very acute situations.

There was also a fairly steady volume of emergency coal to the New York piers, most of which was used to relieve important needs inland from New Haven, New London and Providence. The surplus supply of box barges helped materially when motive power was short.

The great obstacle from a New England standpoint was the Preference No. 1 List and the drastic way in which Washington instructions were interpreted. This territory had a large number of preferred requirements, although in volume of coal used the needs were relatively small. Enormous industries in Pennsylvania were obviously entitled to preference, and it took no great effort on the part of anybody to get them on the list. Many important New England plants, however, were among the 10,000 or more represented in applications to the War Industries Board which were waiting action. Had this plan been followed implicitly, there would have been real disaster to many important industries and untold delays caused to the war program.

Happily, the Fuel Administration devised a new plan of distribution, early in June. The burden of deciding upon the disposition of what coal comes forward to any state was now shifted from district representatives to state administrators, following out the good theory that those on the ground were better qualified to exercise this function. On other accounts the previous program had to be abandoned. Steel and rolling mills had been favored with coal when small plants in New England had had to go without, although their output was just as necessary for war purposes, in many cases furnishing parts that were indispensable. Not enough emphasis had been placed upon "balanced production," and merely because coal requirements were relatively small was no reason for passing them over. In tons of material the output of Pennsylvania, for instance, is much larger, but in the number of men employed per ton of coal New England made a better showing. This territory was working from 65 to 75 per cent. on war

orders, and it was keen realization of necessity that so many officials high in the Government saw to it that New England got its share.

All through the season there were of course abundant instances of the abuse of regulations, price and otherwise. One of the most fertile fields for illicit practices was in the distribution of country-bank or wagon-loaded coal in box cars, a supply which seldom appears except in time of stress. Through illegal price exactions mine-workers were enticed away from standard wage operations and business flourished. To correct this situation and incidentally aid movement to New England all the wagon-loaded coal in box cars on the Pennsylvania R.R. in the central Pennsylvania district was taken over by the Fuel Administration and distributed at the scales by the district representative on consignments furnished by state administrators. This was effective July 22 and continued without pause until September, when a reduced movement to New England was in effect until Nov. 15. There were weeks when 800 to 900 box cars were sent to New England destinations. The method of paying cash on invoice on this coal through banks at Altoona was not calculated to discourage this movement, and it didn't! There was anxiety as to quality and greater anxiety to get the movement stopped, largely because of the 75c. extra price, and the tremendous volume of coal pouring in on New England from every direction; but it came, it was accepted, and it helped plug New England to the point almost of acute indigestion.

In August the all-rail passing figures mounted rapidly, and it was not until well into September that the flood began to subside. Exactly 83.5 per cent. of the rail bituminous for New England was scheduled to come from the central Pennsylvania district, the entire output of which, week after week, was in excess of 1,300,000 net tons. For his courage and initiative in carrying through a difficult program, the District Representative of central Pennsylvania deserves much praise.

A capable inspection force did particularly effective work in that district. Instances were many where cars for New England were withheld because of poor preparation, and more than a few careless operators have been taught that dirt and slate cannot be sold as coal.

By the end of the year the movement all-rail had dropped to 310 cars. The volume would probably not have been greater even had there been active request. It was a great year, and it remains to be seen whether another year will reach the same high mark.

There are so many uncertain factors in the outlook for 1919 that representative men in the trade are not only extremely careful about predictions, but they are reticent. They know that reserve stocks are larger than in any previous year on record; they know that practically every steam-user is figuring on less business; and they hear the extravagant talk about the future of fuel oil in this territory. All that is what everybody knows; but questions whether the Shipping Board will reduce coastwise freights or turn the commandeered steamers back to their owners and thus restore a "market rate," or whether the proportion of rail coal will increase, or whether buying will start in April or in July, or what will be the starting price—nobody knows, nor can anybody venture more than a guess. The disposition in New England, buyers and sellers alike, is to clean house and await developments. Who can say what sort of price the market will settle down to, the withdrawal of fixed prices and the present light output considered, and also who has a very clear idea today as to the offshore market, particularly in South America? These matters time alone will tell.

S.S. "NORFOLK" DISCHARGING POCAHONTAS COAL AT WHARF OF BURTON-FURBER COAL CO., EAST BOSTON, MASS.

What Well Known New York Coal Men Think of the Future—With Some Remarks on Coal Exports

TO OBTAIN an idea of what representative coal men believe 1919 will hold in store for the industry, *Coal Age* has invited comment from a number of large jobbers and shippers who maintain offices in New York City. The following statements are typical of the many answers received, and are reproduced to show the spirit of optimism possessed by men in the trade who are in position to know what they are talking about.

C. B. WYNKOOP, *President of Cosgrove & Wynkoop, Ltd.:*

IT IS odd to note the enthusiasm with which the average coal man of today discusses the possibilities of export and bunker business, while five years ago it would not have occurred to him to seek this outlet for his surplus production. A few of the big fellows had all of the bunker business, and the difficulties surrounding the export end—getting orders, arranging terms of payment, etc.—were so numerous that where an occasional order for export did come along, it was not given as much consideration as an order for a few cars from a little plant on Long Island burning less coal in a year than called for in the one export order. South America and European ports could only be grasped in a hazy sort of a way, and we could not adjust ourselves to the novelty of doing a mail-order business, and doing it in a way that would insure repeat orders.

If we show the same interest in supplying a suitable coal and rendering good service in every detail to the mail-order export customer that we do to the customer located on a line or tidewater point 30 miles from New York, America is destined to become the greatest exporter of coal in the world; and though the New River and Pocahontas coals for a time will undoubtedly come in for the lion's share, there is no reason why all of the better grade coals should not ultimately be in as great demand, if the coal man selling this coal will use the same judgment in the selection of the proper coal for each order that he would exercise for his line trade. In other words, when supplying the export customer if the coal is to be used in power plants which are obliged to burn low-volatile coals because of their boiler conditions, smoke or other good reasons, and high-volatile steam coal is shipped because the price is low and that individual order will net a larger profit, the coal trade is not going to figure in the enormous amount of general export business scheduled to be taken care of by America.

Of course, at the present time only coals going into certain pools are permitted to be exported, and these pools have been selected not because they cover all of the good coals suitable for export, but because the coals in these pools are sure to be good; but as time goes on this list will undoubtedly grow.

It has been suggested that the coal trade organize under the provisions of the Webb law, in which case "the proper coal in the proper place," could be handled as well as a great many other problems that will present themselves as we get further into the business. Many other lines are already reaping the benefits from such organization, and it is to be hoped that the coal trade will get together in some way to take advantage of the opportunities extended to us, as this is a proposition that requires teamwork and coöperation to a greater extent than has ever before been put up to the trade.

Good service and fair dealing in the export end of the coal business must be the watchword of all who are in it, as one irregular transaction will place the entire American coal trade in a bad light. Unfortunately the people of most foreign countries judge the entire American public by the few with whom they come in contact.

In most of the South American countries there are local English, Spanish and German newspapers, all of them constantly boosting the products of their mother country; but America is obliged to do her boosting through individual exporters, and this same condition holds good in many other countries.

It is going to be an uphill climb right from the start, as we will have lots of competition and plenty of criticism, and although it may hurt a little at the start, it will ultimately do us good. The organization of an export trading association that would absolutely guarantee quality and service and assist in securing proper legislation to insure better shipping facilities would almost immediately make us a most important factor in world trade.

C. ANDRADE, JR., *Treasurer of the Matlack Coal and Iron Corporation:*

PRIOR to Aug. 1, 1914, Germany and England divided between them the bulk of the export coal trade to South America. When the war started, Germany, driven from the seas, lost the business overnight; England for a time held it. But England was unable to furnish all that South America required. Thereupon South America turned to the United States; and the United States began in a small way to make a few shipments. To meet this situation, England established an ocean freight differential from Cardiff to South America below the going rates from Hampton Roads to South America, hoping in this way to meet or overcome the competition of the American coal. For a while there was keen and open competition between the English and American coals for the common markets of South America. Then slowly, but very surely, the American coals began to displace the English coals. Under free competitive conditions, the American merchant with his American coal won out.

It was not until the late summer and fall of 1917 that the United States Government began to exercise control over the situation. Three methods of control were devised:

First—The President issued his proclamation of August, 1917, fixing the $2 mine price for coal, and ending with the following beautiful thought: "Under them the industry should nowhere lack stimulation." As everyone knows, the $2 price, instead of stimulating production, curtailed it to such an extent that a few months later Dr. Garfield had to declare his famous

"heatless Mondays." The Fuel Administration had to raise coal prices before the country got back to normal production.

Second—The Shipping Board began to fix ocean rates. Instead of fixing a final rate and letting it stand, it made three or four successive reductions at intervals of a week or so apart, and thereby prevented the closing of many charters—the ships lying idle in many cases while cables were exchanged in an endeavor to keep up with the rapidly changing rates.

Third—The War Trade Board instituted a system of export licenses. The Export License Bureau of the War Trade Board has stood the ordeal of actual trial, and has come out with a clear record of patriotism, impartiality and real efficiency.

Thus, the export of coal was subject to the tripartite regulation of the Fuel Administration, the War Trade Board and the Shipping Board. At the outset the Shipping Board failed to coördinate its activities with those of the War Trade Board. That is to say, the fact that an exporter had secured an export license from the War Trade Board was no warrant whatever that he could secure a ship from the Shipping Board to carry the goods so licensed.

In February, 1918, the Shipping Board began to allocate a large amount of tonnage to one particular party in Rio. In May, 1918, the Shipping Board took over all the free tonnage and thus rendered it impossible to secure any vessels in the open market. In June, 1918, the Shipping Board concluded an agreement with Great Britain by which the British agreed to keep out of Rio, and the Shipping Board agreed to keep United States coal exporters out of the River Plate market.

American Exporters Out of Market

As a result of that agreement, the American coal exporters to the River Plate market have had to sit for the last six months and see vessels sail into Hampton Roads for British account, take American coal for British account, and sell that coal to the customers of the American exporters in the River Plate market. The situation was further aggravated by the drastic charter forms that were forced on the exporters by the Shipping Board.

American merchants had the export coal business of the world in the hollow of their hand, and it was struck down by the inexpert interference of their own Government. Whether or not America can regain this lost export coal trade is a question. It is a demonstrated certainty that she cannot gain it, or even hold it, if the regulation of it is left to the Shipping Board. There is just one thing that will enable the coal exporters to get back their lost trade: Free right to export, and free control of shipping by private owners. Government control is a demonstrated failure.

Wilbur A. Marshall, *of W. A. Marshall & Co., President of the Lincoln Coal Co. and chairman of the Bituminous Operators Committee of the Wholesale Coal Trade Association of New York:*

TO PREDICT with any degree of certainty the outcome of the coming evolution in the coal trade is a difficult matter. Predominating interest centers around the question of price, the labor situation, the possibility of securing foreign markets, the local demand and, with consumers, the question of quality.

There has been a great fear that coal prices would tumble and that there was a danger we would get back into the old rut of doing business without profit. Upon giving a little study to the situation, it does not appear that there is particular reason to fear such a condition. Giving consideration to the fact that there is today a tremendous stock of coal above ground, and that there is still an excess demand for the high-grade gas coal and for all of the higher grades of smokeless coal and that there is a greater desire on the part of consumers than ever before to secure quality, does it not stand to reason that the bidding for quality would cause good coal to advance if the price restriction was removed?

Poorer Grade to Bring Lower Prices

Taking another viewpoint: The Fuel Administration in fixing prices ignored entirely the question of quality, which resulted in the fixed price for Westmoreland gas coal, possessing a high standard of quality, being much lower than the high sulphur coals of the Fairmont region. With the removal of price restrictions it is readily seen that there will be an immediate advance in the price of coals from the Westmoreland district. That there will be a reduction in the price of poorer grades is evident, and it is quite in order with good economics. Reduction will depend largely upon quality and the decrease that may be brought about in the cost of production, which leads us to the consideration of labor.

Labor has been and is now independent. Wages in the coal-mining industry top any other that we know of, time employed considered. Miners are averaging upward of $8 per day of eight hours, and the daily average is nearer seven hours. The cheapest sort of labor generally gets 49½c. per hour, and usually works ten hours per day. Labor has announced that it will not accept a reduction in wages, and in the coal mines it is doubtful if there will be any material reduction in the rates for some time to come. Most mines have been and still are working with from a 50 to 75 per cent. supply of miners and many company men 60 years and over in age are doing work formerly done by young men. As a result the overhead is a burden on cost. This cost, through efficiency, will be cut with the return of younger men, except for one possibility. Many of the miners are of Austrian, Hungarian and Polish nativity, and a number of them have signified their intention of returning to the old country during the present year to see members of their families. Most of these will return in due time, but there is danger of a shortage for this year at least.

There is a constant and persistent effort being made to spread the control of unionism, with its usual effect in the way of petty strikes and interruptions, all for the sake of recognition or the gaining of special pay for some detail of work. This situation prevails mostly in Maryland, West Virginia and Kentucky, formerly nonunion districts. Short-time mining will be the best cure for this situation.

All Eyes Turned to Export

Everyone has his eye on the export situation, either with the hope of securing a part of the business or trusting it to take the excess of supply and help maintain the local market. Too much of this business cannot be expected. In the first place other commodities will be in as great demand as coal, and the available tonnage, being limited, must be divided. There is and will be a market for export coals of the standard export grades known to foreign buyers, but the limitations on shipping facilities will probably be a disappointment to even the shippers of those grades. It is doubtful if any material headway will be made by the novices during this year at least.

In this line consideration must also be given to the effects of trades accomplished by British traders, who have already by agreement and otherwise tied up a large amount of the business that might be expected to come naturally to this country. As a result English coal will be supplied when available and the overflow be bought and shipped by the British from here. Fuel oil for foreign use will probably be a large factor of competition than heretofore. The increased use of this fuel will depend largely upon the speed with which tank stations are installed, but in all probability no time will be lost in this direction.

Local demand will be limited until present stocks are consumed, which will be around Apr. 1. Following that there should be a healthy demand, especially for high-grade coal. There will be a limited demand for the poor grades, and the chances are that small mines opened during the past year and producing small amounts of poor coal will close down by the hundred.

As a final résumé, we look for a period of three months of uneasiness and uncertainty, following which we expect to see a good steady business at profitable figures, probably above the present fixed prices on good coal with a reduction in the production and price of poor coal ranging from slightly under the present fixed prices down to the cost of producton, and in some cases less than the cost of production, depending entirely upon quality.

C. C. HARRIS, *of G. D. Harris & Co.:*

A FORECAST of the future, so far as it affects the coal trade, is a difficult undertaking owing principally to the number of "ifs" that one is confronted with at every turn. I would not presume to predict the conditions which will be existing a year hence. Some look for unparalleled prosperity, while the darker side of the picture can be seen by many intelligent thinking men. However, there is no question but what with proper legislation, particularly as respects foreign trade, and with a fair settlement at the peace table of foreign relations, our coal trade certainly should not experience for many years to come the demoralized conditions which existed prior to and just after the war started. Neither should it be expected that the inflated market due to war necessities of other countries should ever have a recurrence here.

As to the immediate future, I am willing to venture the opinion that the same holds forth no encouragement for the ordinary coal man. The consumers of coal are readjusting their business to peace conditions. There is no question but what there is a decided slowing up of production all along the line, and even were it not for this process of reducing operations, the average consumer of coal is not under the strain and stress that he has been to negotiate for his future supply of coal. He will endeavor to secure his supply on better terms to himself than he has enjoyed for the past many months.

The consumer of coal who has been producing essentials for the Government has, of course, been taken care of by the Government; his every want and requirement has been supplied. He has obtained coal from here, there and everywhere, and has paid all kinds of prices for it. His stock yards are full to overflowing. He may not have the coal he wants, and he may be disappointed at the price paid. His first impulse therfore is to use up and get rid of these stocks. It is a well known fact that many consumers who required 1000 tons to see them through the winter have had 2000 tons shipped to them. Obviously this consumer is out of the market for months to come. Perhaps the concern that has supplied him for years has not had the privilege of shipping him one pound of his coal. This coal concern, therefore, has to find other customers.

An argument frequently heard is, that granting the essential consumer has been supplied and taken care of as stated above, he now becomes a non-essential, and the former non-essentials are now first-class preferentials. The logic of this is quite true, and it would be reasonable to expect that these former non-essentials were all of them desperately in need of coal. Is this a fact? Answer, It is not. Many non-essential plants which have no license whatsoever to have a stock of coal on hand today are filled up and not interested in any purchases at this time. It is very evident that the huge production of bituminous coal, together with the forcing upon the market of small steam sizes of anthracite and culm, has supplied all the essential plants; and there has been enough overflow to take care of the former non-essentials. The situation in the great consuming market of New England bears out this statement, and therefore until stocks are reduced it is going to be difficult for coal operators and distributors, except those producing the very highest grade of special coal, to find a ready market for their product.

PREDICTS PERIOD OF ACTIVITY

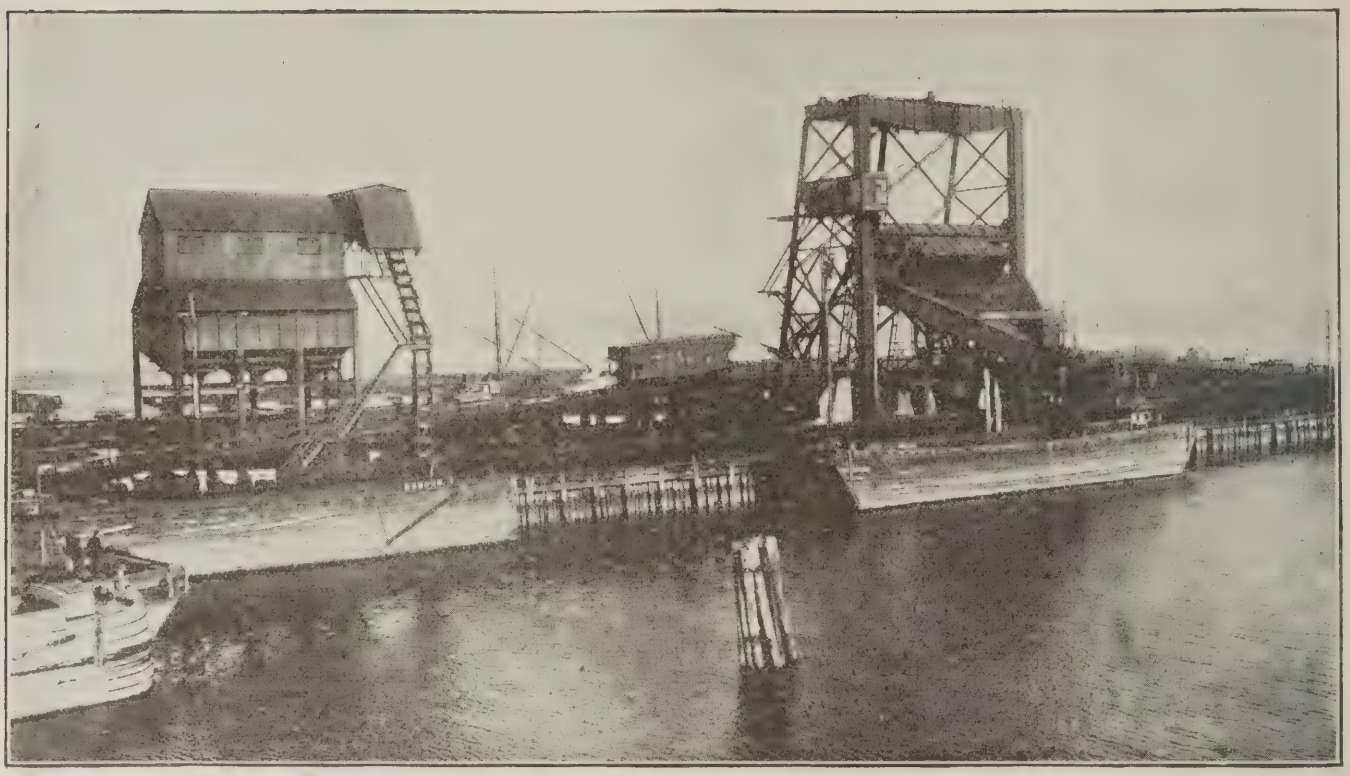
I do not say that there will not be a period of activity; the moral effect of bad weather, poor transportation and inadequate car supply will cause some apparent shortages, and will also produce a feeling of uneasiness in some directions, so that at times during the next three or four months there will be a good demand for coal and prices will be maintained. Should the Government restrictions be removed, there will probably be a little more freedom of action for the coal distributors who may be tempted to send out their salesmen once more and endeavor to move tonnage toward their usual customers, obtaining for the same a fair margin of profit above that which they are obliged to pay for coal.

With the continuation of Government control it is my opinion that it will be difficult to move tonnage. The operator naturally will endeavor to get the full price; the consumer will likewise very naturally not desire to pay any more, and the distributor will experience difficulty in finding his proper place in the movement of coal from the mines to the consumer. All of this may have a tendency toward the elimination of the wholesaler from the situation. This, if accomplished, would be a genuine disaster to all those concerned.

There is no good reason why the wholesaler cannot hold his place if he takes ordinary business precautions to protect his interests. This can be done through organization and coöperation, by taking advantage of the experience of other lines of trade, practically all of which are strongly organized, and following the lead of many other branches of industry, which have been in similar circumstances before this. Trade organizations are held in respect by all interests, and I believe looked upon with favor by the Government.

ARTHUR F. RICE, *Commissioner of the Coal Merchants Association, of New York City:*

IN ATTEMPTING to forecast the conditions likely to prevail during the coming months, we may think of some things as reasonably certain. While the Fuel Administration will automatically cease to exist with the signing of the peace treaty, there is little likelihood of that occurring before the end of the coal year, and Federal control will probably continue at least to that time.



The increased production of bituminous coal, in the face of a decreased demand both here and abroad, will probably give the market all the soft coal it can digest—and some to spare—with a tendency to lower prices. With regard to the egg, stove and chestnut sizes of anthracite, the indications are that the absolute needs of the consumers will be met and that there will be an abundancy of broken and pea. On Nov. 26 there were 15,000 tons of broken and 45,000 tons of pea in the hands of the dealers in Manhattan and The Bronx, with practically no sales for these sizes. Normal conditions may be a long way off, but as they begin to arrive the prices for coal, which are unreasonably high, will come down of their own weight, and with a more plentiful supply the differential between "company" and "independent" coal will be apt to efface itself.

The things we shall have to guard against are a renewal of unrestrained competition and the old habit of scrambling for business without due regard for price or profit. And yet the situation is full of encouragement. Never in the history of the trade has there been such uniformly good feeling among the dealers, every one of whom is a member, in good standing, of this association. All have learned the cost of doing business, all have discovered that it can be transacted at a profit without violating the laws of decency and common sense.

War conditions and the Government have controlled our industry for the past two years, but there are strong indications that hereafter we shall be better able than ever before to control it properly ourselves.

Europe as a Market for American Coal

"Ships and freight rates are the governing factors in the matter of supplying Europe with American coal," says Walter E. Hope, who studied conditions on the other side. The situation in France is critical. The mines at Lens were completely destroyed. From one to three years will be required to reopen these mines. Frenchmen pay $17 a ton for household coal. Industries are charged $25. At least one-half of the coal supply of France must come from outside her borders. American coal is wanted, and a market is waiting if reasonable shipping rates are arranged.

LEHIGH VALLEY RAILROAD CAR DUMPING MACHINE AT PERTH AMBOY

New York Coal Trade in 1918

By R. W. MORRIS
Brooklyn, N. Y.

THE anthracite market opened the new year in vastly different condition than it did a year ago. Instead of record-breaking temperatures and a lack of coal, the weather reminded one of early fall temperatures, while there was enough coal in one place or another to take care of the situation for several weeks to come. Due to the insistent demand and the urgency of the Fuel Administration and coal dealers, everybody who was in a position to do so had at least a part of his winter supply of fuel in the cellar bins; and in most instances at least two-thirds of the orders placed with the local dealers early in the spring had been delivered. In some cases the remaining one-third had been cancelled by the consumer on the ground that because of the mild weather so far experienced it would not be needed.

The first of the year saw business at practically a standstill. Dealers had some orders on their books, but there was no urgency about deliveries, and the dealers were not anxious to pay the full price for "independent" coal when it was expected that with the lack of demand they could soon secure "company" product at 75c. per ton less than they would have to pay for "independent" product.

The retail dealers began the new year by granting an advance in wages to their drivers and chauffeurs of $6 per week, in addition to a nine-hour day. This was the second advance granted within twelve months, and naturally resulted in an increase in the retail price of coal.

It was early in the year that the Board of Aldermen adopted an ordinance giving the Mayor power to confiscate all surplus coal in the city wherever situated, the price to be paid to the owner to be fixed by the courts. If any coal has been seized under the power of this ordinance it has not been announced. However, the Police Department, under direction of the Mayor, made a survey of the coal situation throughout the city and secured gifts of $17,000 and 1000 tons of coal, which was distributed among the needy.

During the year many plans were suggested for overcoming conditions that existed in the city last winter. One scheme was to store coal in the Central Park reservoir, but this and many other ideas were never put into use.

Early in the year, in order to prevent extortionate prices being exacted, the County Fuel Administrator, Reeve B. Schley, established maximum prices for the peddlers, of which there are about 10,000 in New York City. At about the same time State Fuel Administrator Wiggin recommended the pooling of anthracite and a reduction of sizes. The latter had been advocated for several years. The first named recommendation was adopted by some of the shippers, but it did not continue.

DUMPINGS OF ANTHRACITE AND BITUMINOUS AT TIDEWATER PIERS IN 1918

	Anthracite	Bituminous		Anthracite	Bituminous
January	24,064	19,277	August	32,417	30,157
February	22,876	17,268	September	28,119	30,328
March	31,224	23,810	October	27,190	28,503
April	28,548	23,084	November	21,834	25,470
May	29,835	28,104	December	26,261	25,169
June	30,695	30,240			
July	32,228	31,155	Total	335,291	312,574

The local situation was not relieved until higher temperatures prevailed, and then the coal began to move easier. Meantime the Fuel Administration has been assisted in handling the situation by a committee of retail dealers.

Almost simultaneously with the warning issued by the Fuel Administration that consumers should place orders for winter fuel early, Dr. Garfield announced a reduction of 30c. per ton in the price of coal at the mines, which of course meant a similar reduction at tidewater. In a comparatively short time the retail dealers had received orders from nearly all of their customers, although there was no prospect that the coal could be delivered before fall or the early winter. Then followed the increase in freight rates, and a cut of 25c. per ton in the gross margins allowed the retail dealers, which in addition to the decrease in price announced by Dr. Garfield meant a reduction of 55c. by the retailers.

As a result of the heavy call for anthracite from all parts of the country, and the belief of the officials that New York, because of its nearness to the coal fields, could be supplied with fuel later in the season than could other sections of the country, shipments to this market did not come forward as rapidly as the trade desired.

After much time had been spent by various officials, dealers and others in explaining to the public that coal was being handled here as rapidly as received, the Labor League held a meeting in the City Hall and adopted resolutions insisting that the dealers store more coal, but not suggesting where the coal could be obtained.

The allotment of anthracite for New York State was announced by the Anthracite Committee as 15,855,300 tons, an increase of 11.89 per cent. over the 1916-1917 tonnage, of which about one-half came to New York City.

Early in the summer the city officials announced that they had closed negotiations by which this city was to receive 300,000 tons of anthracite coal, which would be sold to the poor. This coal was to be obtained from culm banks in Schuylkill County, Pennsylvania, but so far none of the coal has arrived.

Demand continued strong until late in November, when as the weather kept mild and consumers had no occasion to keep their furnace fires going at top speed, there was a lull, and dealers began to receive notices from their customers to cancel their orders. Even while this was going on Mayor Hylan ordered the Police Department to make another survey of the coal situation, and notwithstanding a strenuous protest from Dr. Garfield it was made, resulting in a report to the Mayor showing a deficiency of 3,577,261 tons in the city's supply.

In December business became inactive. There were plenty of most of the sizes to go around, but no surplus. Retailers who were buying considerable "independent" product cancelled their orders, relying entirely on "company" coal, which was purchasable at a price 75c. per

PENNSYLVANIA RAILROAD CAR DUMPING MACHINE AT SOUTH AMBOY

ton below what they would have to pay for the former product.

The situation with regard to the anthracite steam sizes is one of much concern and will likely remain so for some time to come. Since early summer these coals have been a burden to the market and toward the end of the year shippers had some difficulty in reducing their stocks. However, one benefit derived from the scarcity of the domestic sizes during the year and the educational campaign conducted by the Fuel Administration forces was the using of buckwheat No. 1 in household furnaces. Considerable of this size has been used in this city, and while it has already meant a considerable saving to householders, it will continue to do so for some time to come, and probably forever.

The bituminous market had many ups and downs during 1918. Instead of the scarcity of free coals available for the spot buyers and poor car supply that prevailed in January, 1918, the first month of the new year saw an overabundance of free coals here and a good car supply. Early in the fall, and just before the armistice was signed, consumers began to hesitate about adding to their holdings; and demand, which had been heavy throughout the previous months of the year, began to dwindle away. This was followed by an almost cessation of business when the fighting "over there" actually

BITUMINOUS SHIPMENTS TO NEW ENGLAND DURING 1918

	1917	1918		1917	1918
January	152,449	129,267	August	199,591	371,554
February	129,299	124,013	September	203,339	390,183
March	163,818	231,549	October	213,500	398,054

May	228,091	336,072	December	124,735	.....
June	217,168	325,710			
July	190,328	356,314	Totals	2,221,939	2,836,231

stopped. Consumers who had been willing and only too glad to take anything that looked as if it might make steam, now stopped buying altogether and announced that they wanted nothing but the best grades, with the result that there soon was a surplus of the cheaper grades; and toward the end of the year there were concessions from the Government's maximum prices.

Not from January until well on toward the end of the year was there sufficient bituminous coal to take care of all demands. War requirements were of course taken care of first. This, together with what could be shipped to consumers who required the better classes of coal, took the entire output of the good as well as the cheaper grades of coal.

Bunkering of vessels took a considerable portion of the shipments to this harbor, and this was carried on on a larger scale than ever before. At one time it was estimated there were about 200 vessels here, most of which were waiting for coal, either for bunker purposes or for cargoes.

The threat to close theaters and moving picture houses in order to conserve fuel met with strenuous opposition from the owners, who contended that each day's closing meant a loss of $11,800 in taxes to the Government, while the value of the coal saved would be less than $163.

One result of the scarcity of coal was the extra demands made on the gas companies. The companies were doing the biggest business in their history for several weeks, so much interest being taken by the public that the newspapers published the number of cubic feet of gas manufactured and furnished to the public by the companies.

Although the miners were doing their utmost to keep the country supplied with fuel, additional emphasis was put on the need for increased production and better preparation by an allowance of 20c. per ton for clean coal. This tended to help matters some.

In June exporters and shippers who sent coal from Hampton Roads and other southern ports to points along the New England coast, and also to South America, were compelled to suspend shipments for a few days owing to the presence of enemy U-boats off the coast. Several loaded coal vessels were sunk nearby.

There were many changes made during the year in the pools and more changes are contemplated this year. A reduction of 10c. per ton in the margin granted jobbers for coal physically handled by them caused much discussion among the trade, but all gladly accepted the ruling. An early order had granted the jobbers a margin of 35c. per ton, but State Fuel Administrator Cooke soon after taking office reduced this to 25 cents.

The order issued in November allowing traction and lighting companies to accumulate 100,000 tons of coal relieved the local situation slightly by disposing of some

coal that would eventually have found its way to the tidewater docks for public sale.

The number of cars of bituminous coal dumped at South Amboy, Port Reading, St. George, Elizabeth and Port Liberty, which are under the jurisdiction of the Tidewater Coal Exchange, during 1918, totaled 250,120.

The Harsimus Cove, Communipaw and Weehawken piers are not under jurisdiction of the exchange.

Coal Production in the United States in 1918

The following table has been compiled largely from data communicated by the various state mine inspectors, estimates having been made only where no such statistics were available, but in all cases upon the basis of reliable information. Where these figures differ from those given in the text of the reviews, the discrepancy is due to late telegraphic reports necessitating changes in the totals.

PRODUCTION OF COAL IN THE UNITED STATES

States	1917 Quantity Short Tons *		1918 Quantity Short Tons
Alabama	20,068,000		20,000,000
Arkansas	2,144,000	(a)	2,375,000

Petroleum Production and Exhaustion

By L. P. Breckenridge
Sheffield Scientific School, Yale University

The accompanying charts show some interesting figures on petroleum production and exhaustion. Fig. 1 shows how the production of the United States has compared with world production from 1880 to 1917. It will be noticed that since 1905 this country has produced between 60 and 70 per cent. of the crude petroleum of the world.

Fig. 2 shows the estimated degree of exhaustion of the known fields in this country. It will be observed that five fields—the Kansas-Oklahoma, North Texas, Gulf Coast, Wyoming-Montana and California—are less

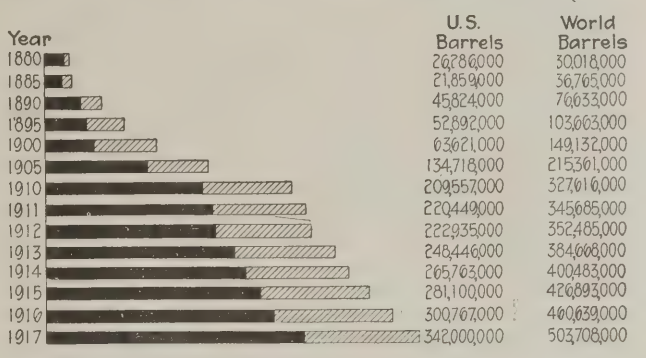

FIG. 1. PRODUCTION OF PETROLEUM IN THE UNITED STATES COMPARED TO REST OF WORLD'S OUTPUT

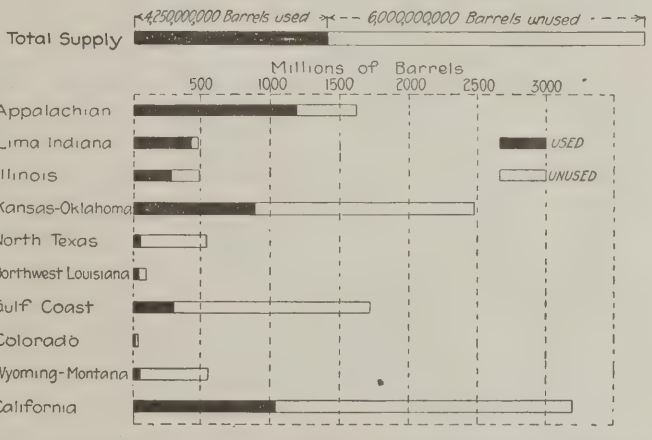

FIG. 2. ESTIMATED DEGREE OF EXHAUSTION OF UNITED STATES OIL FIELDS

than half exhausted. Some of the others, particularly the Lima-Indiana and the Colorado regions, are rapidly nearing complete exhaustion.

Such charts as these, while they must necessarily be more or less uncertain since they are at best merely estimates, serve as indications of what the future will certainly bring forth. Much of our modern industrial life as well as our pleasure depends upon the internal combustion engine that now uses petroleum or some of its derivatives as fuel. It would appear that the day is not far distant when this country must either import oil from other lands, must adopt a new fuel, must manufacture the present fuel from sources other than petroleum, or must seek means of motive power other than the gasoline engine.

Philadelphia Coal Trade in 1918

By CORRESPONDENT
Philadelphia, Penn.

THE year 1918 was truly historic in local coal annals, the outstanding feature being the fact that the business was practically taken over by the Government, both production and distribution, more particularly the latter. As time passes this phase of the situation will become more apparent as being a time when the distributors of coal worked directly under Governmental supervision. Yet today it is difficult to find a man connected with the trade who will be willing to say that it was not for the best; and even the consumer, when hard pressed, will admit that were it not for this supervision he would more than likely have been compelled to pay $25 or more a ton for coal during the zero days of January, 1918.

At that time the yards of the city were bare of coal, with the most severe weather the city had ever experienced. Despite urgings all the previous summer, most consumers had failed to take advantage of the opportunity to store coal. It was during this period that in some sections of the city the situation became so acute that people robbed the cars on the street before they could be delivered to the dealers' yards. Thousands of tons were taken in this way, the loss falling on the railroad companies, who later in the year reimbursed the dealers. The severe weather broke up in February and gradually moderated right on into spring.

Fuel Authorities Planned for Future

In the meantime the fuel authorities, profiting by their experience of the winter, had already laid plans for the following season. It was decided that all coal deliveries would be supervised by the County Fuel Administrator. He devised a system of card ordering, whereon each consumer was required to state the amount of coal used during the past season, together with details as to size and construction of his home, the kind of heating apparatus and the estimated amount of coal needed. These cards were checked through a central bureau, the expense of which was defrayed by a stamp tax of 2c. per ton.

With the approach of Apr. 1, it was for a time thought that the usual spring reduction of 50c. a ton, reducing 10c. each month until the circular price was reached in September, would be abandoned. However, the Fuel Administration decided upon a flat reduction of 30c. a ton from the circular price, the full rate being reached on Sept. 1, which would actually result at that time in the winter circular being 20c. higher than the previous winter.

A spirited and widespread campaign was started to urge consumers to store coal in the summer, and this was readily responded to by the public. As a matter of fact the orders piled up much faster than the dealers could handle them, and in the meantime the shipments during the summer fell off so much that the dealers for weeks at a time had their equipment idle for lack of coal. It was explained by the distribution committee that they were endeavoring to fill up outside markets, such as New England and the Northwest, and that this city would be taken care of in the fall.

All summer long the dealers clamored for more fuel, but it was not forthcoming. The administration also ruled that no consumer could receive more than two-thirds of his entire order prior to Jan. 1. Even though the dealers did not receive all the coal they could handle, it is a fact that more coal was stored in the cellars than ever before. With the coming of fall the weather continued quite moderate, and even right through December to the first of the new year the weather was such that the demand for coal fell off very considerably.

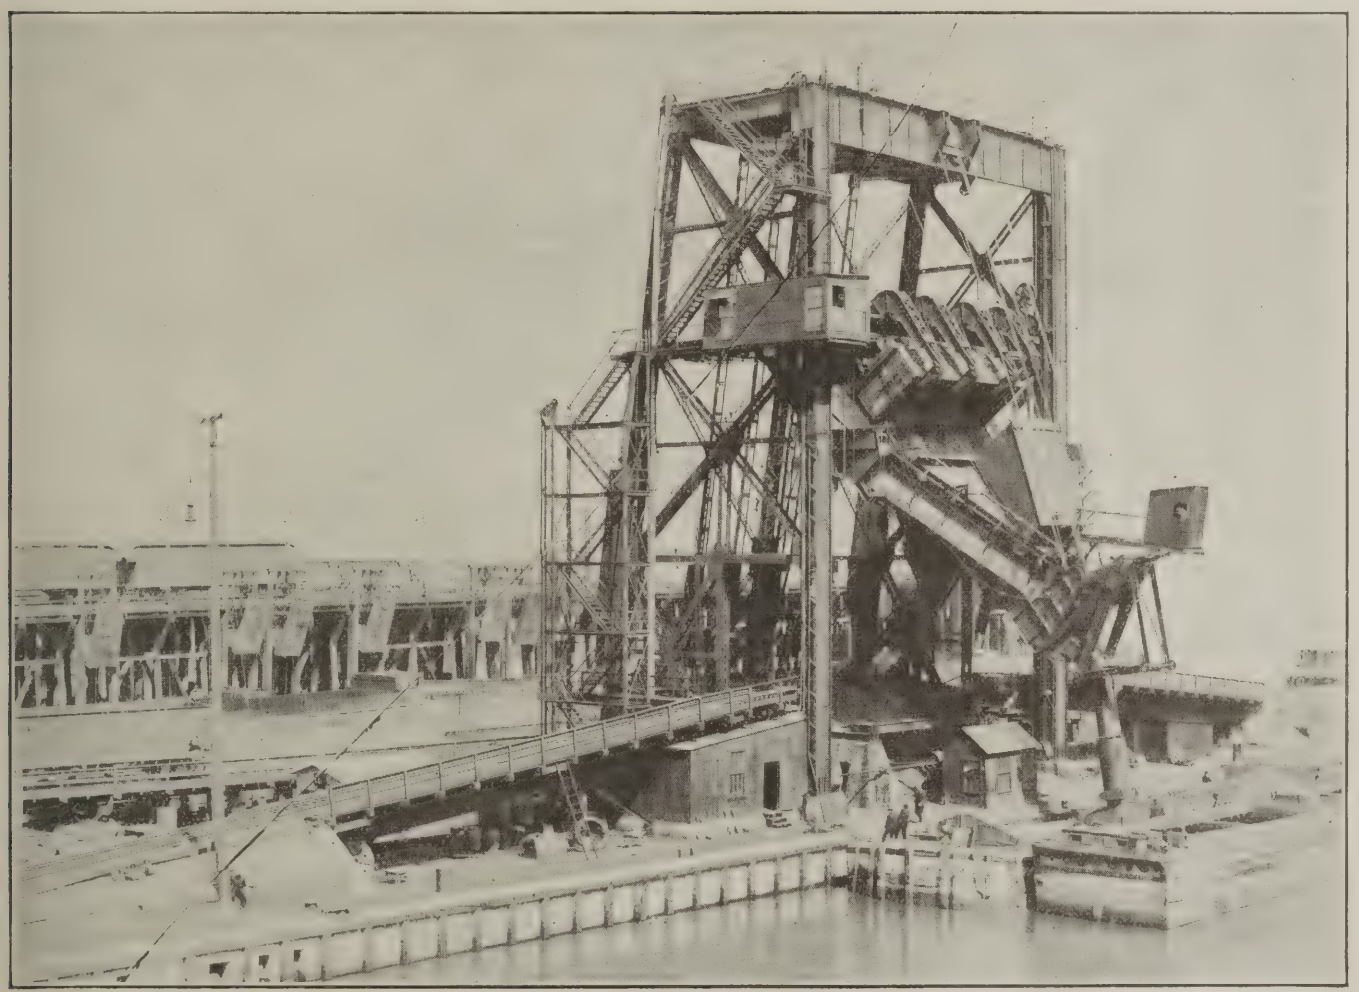
This condition was reflected later in the year by a lack of demand for egg and pea coal. The consumers became quite insistent upon receiving the sizes ordered, which at this time were principally stove and nut. The situation became so serious that the Fuel Administration endeavored to convert the public to the use of a mixture of egg and pea, using a series of advertisements in the newspapers for this purpose, but with little success in reducing the accumulation.

Profitable Year for the Dealers

Reviewing the year it must be said that it has been a most profitable one for the dealers, despite what they considered handicaps. It is true that individual effort was curtailed to a great extent, so that no dealer could go after trade, but was really confined to the business that he had been accustomed to in previous years. However, with the fuel authorities putting the business on practically a cash basis, all credit losses were stopped automatically. Also the fact that the administration fixed a gross margin of $2.50 on Apr. 1 made it exactly clear to the public that the dealers were not profiteering at their expense. The retailers are at this time in strong financial position, although there has been a feeling that due to the rapidly increasing costs toward the latter end of the year they were entitled to a greater gross margin than $2.50, especially in view of the fact that the wholesale price of coal was increased $1.05 on Nov. 1 by the national administration in order to meet the miners' demands for an increased wage scale. No part of this increase accrued to the dealers, although their capital investment was greatly increased thereby.

As to the future the retailers are much concerned to learn whether they can keep their business on the same firm financial basis. Even at this time, with the relaxing of war effort and the reduction of working forces in munition plants, there is an increasing demand for credit by the consumers, and many dealers are actually putting more money out in this way during the first few weeks of the new year than they did in the entire year of 1918. This matter is also giving the producing companies considerable concern, as they are extremely anxious to keep their accounts with the dealers closely paid up.

There can be no doubt when the Fuel Administration relaxes control some time between now and Apr. 1 there



will be many changes in the trade. There is a general feeling that with the individual prices so much higher than the company prices there will be violent price shadings, particularly since the moderate weather up to the first of 1919 has made the production somewhat difficult to market. It is also thought that after Apr. 1 the operators will be in for some rather dull times, as there is not the least doubt that the consumers will be loath to lay in the same quantity of coal that they did during the previous summer, when our war effort was at its height.

In the steam trade there has also been remarkable changes. Early in the year the mines and washeries were far from able to meet the demand for fuel. In the effort to meet the fuel needs of the country thousands of tons of culm, which had lain in the banks at the mines for years, was shipped all over the country and mixed with bituminous coal, as high as $1.50 a ton being paid for it at one time. This extreme demand for steam coal broke early in the summer and there was a gradual tapering off, until when November was reached all sizes but buckwheat were actually a drug on the market. The larger companies were compelled to store rice and barley in their storage plants, while culm went completely out of the market. Even with the coming of the new year conditions in steam coal did not improve, and at this time the disposal of these sizes is becoming a serious question, with much talk of price lowering in order to move the coal.

One thing is certain, and that is the market has absorbed more anthracite steam sizes in the past year than it will again take for many a day, and it is altogether likely that numerous washery operations built by the big companies during the war will close down completely on this account. However, the matter of price is bothering the producers more than anything, and there are grave doubts whether in the face of increasing bituminous production they will be able to maintain during the coming year anything like the scale the smaller anthracite coals have enjoyed during the past twelve months.

The local market probably took more bituminous coal to fill its requirements than it did in any previous year. Earlier in the year, during the heatless days, it was necessary for the fuel administration to commandeer coal in order to meet the pressing industrial needs. While there was at the first much complaint made at the fixed price insisted upon by the Government, later events proved that this was really a saving feature for the bituminous trade.

As more open weather came on the production of bituminous naturally increased, together with a more efficient car supply, until early in the fall more coal was reaching here than the market could absorb. All the big industrial plants were piled high with reserve stocks, and when the war ended there was a sudden canceling of many orders for fuel, as the consumers were momentarily expecting a price reduction. All

PENNSYLVANIA RAILROAD CAR-DUMPING MACHINE AT GREENWICH POINT, PHILADELPHIA

the while, however, the high-grade coals were in strong demand, and the call was so heavy that no thought of price recession was entertained; but with the cheaper grades there was much price cutting, quietly of course, and at times some of these shippers had difficulty in getting $2.60 for their output, especially in the closing days of 1918.

At this time the soft coal men are hoping that the Fuel Administration will continue to supervise the trade until April, and at that time there seems to be no doubt that the coal business will once more be returned to the producers. On account of the many new openings in the region there can not be the least doubt that prices will fall much below the present Government schedule, and the shippers are at this time looking forward to that time with much anxiety. As a matter of fact many in the trade are strongly in favor of the Government keeping control of the bituminous situation, at least to the extent of maintaining prices so that the business can be conducted at a living profit.

Anthracite in New England in 1918

By G. G. WOLKINS
Boston, Mass.

SYNOPSIS — *Steady demand. Record tonnage by rail but receipts by water slumped materially. Grave situation in January and February. Costs mount high. Regulation carried too far and later into the season than necessary. "Emergency" coal in the fall puts trade to great inconvenience. More hopeful prospect for retailers. Heavy tonnage of steam sizes.*

A LARGELY increased tonnage, sharp advances in cost, and a sustained demand for domestic sizes were the leading features of anthracite in this territory in 1918. A long hard winter wiped out the reserves, whether in dealers' bins or in the cellars of householders. Distribution was made only through channels authorized by the Fuel Administration, and every shipment, every delivery by team, was assumed to be carefully scrutinized. Notwithstanding all the efforts to conserve and most drastic regulations designed to cover its use, more coal was passed around during the twelve months just ended than in any year in history.

For most of the year distribution was "spotty," but this condition righted itself toward the close when shipments came more easily. Throughout the twelve months the usual trade factors were but little more than cogs in a machine. The judgment of houses long in the business was seldom taken into account after deliveries were diagrammed on the basis of the year that began Apr. 1, 1916. In New England this worked hardship to many communities where forehanded dealers had taken pains early that year to get coal forward in anticipation of labor troubles in the spring. When increases in tonnage were granted and allotments left to state administrators, there was so much uninformed figuring that a good many towns would have been in a hard way but for the mild season and the indications in December that the fuel authorities would soon relinquish control.

In general, there was more anxiety over supply in those communities where there were dealers with weak connections. The larger companies had shipped full quotas by Dec. 1, but most of the "independent" shippers were in arrears. The Anthracite Committee seemed not to have the same effective control of the latter, and this came out very prominently during the summer and early fall. Difficulties arose from the tonnage placed during the basic year by chains of middlemen, all of whose dovetailing transactions were not easy to trace.

Another feature was the reduced tonnage by water. The further commandeering of tugs for the Navy, higher marine freights, and the difficulty of putting boats and coal together at the New York piers, all contributed to the increased movement all-rail. There are retail dealers always equipped to discharge boats whose entire receipts during 1918 were by rail, and at no time during 1918 was there such congestion as to make it necessary to place an embargo against coal for points far to the eastward.

During the record low temperatures in January practically the only supply of domestic sizes for ten days was in special trains from the mines. One trainload was diverted from Camp Devens to meet pressing emergencies in Boston. The famine was so acute that temporary fuel stations were opened in the poorer districts. Wealthy citizens had coal taken from the cellars of their country houses and hauled over the road for use in the city. Meanwhile receipts by water were extremely discouraging. The Delaware River froze tight and dumping at New York slowed up, so that it was increasingly difficult to run the gantlet of watchful New York retailers. Both the big city markets were after coal strong, and it was not until after the weather moderated that barges again came forward in any number. Cargoes were ill-assorted; stove and chestnut were very scarce, and retail prices were advanced in Boston from $9.85 to $10.25. Not only were several retailers there without a ton of domestic sizes, but there were several towns and some cities where householders were forced to use bituminous at about the same range of price.

Even in March there were retailers usually in favorable position who were without anything like a continuous supply. The movement improved very gradually. Loading was better, although normally it would have been considered very poor. There was renewed anxiety about tugs. One company alone had 24 barges at one time waiting in the Delaware, and but three tugs en route. In another month it looked impossible for both rail and water movement to speed up enough to give

New England the increased percentages promised, in addition to the 1916 basis. The Eastern dealers, in particular, were alarmed over the outlook.

"Spring prices" were announced in Washington early in April, and when to these were added 50c. increase in freight tolls from mines to tidewater June 25, 35c. on Sept. 1, and $1.05 effective Nov. 1, it was realized that anthracite was getting to be a very expensive fuel.

The year developed an even wider variation in marine freights in company-owned barges. The rate on anthracite in Reading barges from Philadelphia to Boston was advanced from $1.25 to $1.50 on Jan. 28, and again 30c. on June 25, being operated by the Railroad Administration. On Dec. 28 a further advance of 30c. applied on all cargoes delivered east of Newburyport, Mass. The present rate to Portland is therefore $2.10 as compared with the 75c. rate that prevailed less than two years ago. At the same time the rate on barges owned by the Lehigh & Wilkes-Barre Coal Co. was $1 (plus docking) until May 11, when an advance of 50c. applied, since unchanged. The Lehigh Valley R.R. barges held to a level rate of $1.30 to Boston from Perth Amboy until Dec. 28, when it was scaled up by the Railroad Administration to be on a parity with the Reading.

Settled weather during June helped toward better movement of tows. Rail receipts were also improved. Output was reported on a 90 per cent. basis, although stocks in retail yards were 25 per cent. less in Boston than in 1917. Under instructions of the Anthracite Committee points farthest east and up the rivers were favored in shipments the first of the season, although later on it was evident that the movement of barges was so slow that no special gain was made.

At the end of May it was announced by the Fuel Administration that 1,250,000 net tons monthly of domestic sizes would be furnished New England, distribution to continue on the 1916 basis. This was a decided marking up of quota, but it was several weeks before the trade felt the result of restricting domestic sizes from the Middle West and from the South Atlantic states. When in July a tow of barges was fired on by a U-boat, shippers were instructed to increase all-rail deliveries to points ordinarily served by water. Receipts by the latter route sagged notably.

Retailers were further disturbed over the strict way in which fuel committees ruled that apartment houses having over a certain boiler equipment should be obliged to use bituminous. The effort at Washington to shut off domestic sizes from industrial plants was loyally supported by state administrators here. It took a good deal of enlightening argument in many cases to get "exemptions" and "permits" in favor of manufacturers who were in every sense retail dealers in anthracite for their own communities, but gradually most of the cases were straightened out. The regulating spirit died hard, however, and at the end of December, a time when many shippers were soliciting orders, the Fuel Administration was keeping a tight grip on domestic sizes that shippers wanted to send to factories, etc., for the use of employees, as they had done from time out of memory.

A mild sensation was caused during July by the long telegrams sent from Washington by the statistics division to "retail dealers" who were alleged to have neglected making reports. The number of delinquents, however, was entirely misleading. The names of 1200 "dealers" must have been based upon cumulative lists of consignments of from one car up for several years. The names had not been checked by anyone conversant with New England trade, and besides the many who had consistently made reports there were scores who had gone out of business eight and ten years before.

To a surprising extent the owners of box barges showed throughout the year a disinclination to charter for Boston. Rates supervised by the Shipping Board allowed $2.50 to Boston anchorage at the same time that $2.15 was the rate to New Bedford. The lack of towing service through Cape Cod Canal was a factor in making outside barges scarce for Boston.

On July 18 Boston retail prices were advanced 75c., to $11 for broken, egg, stove and chestnut to cover increased freight charges, and 40c. instead of 25c. began to be charged for basketing. There was the usual agitation in Boston and other cities over iniquity in the coal business and in favor of municipal yards, etc. A mere advance of 25 per cent. by the Government management of railroads meant nothing to city fathers, who showed surprise and resentment over any advance in retail prices.

APPROXIMATE COST OF READING COAL ALONGSIDE BOSTON DURING 1918

White Ash	Jan. 30	May 1	July 1	Sept. 15	Nov. 15
Broken	$7.86	$7.84	$8.66	$8.96	$10.01
Egg	7.76	7.44	8.26	8.56	9.61
Stove	8.01	7.69	8.51	8.81	9.86
Chestnut	8.11	7.79	8.61	8.91	9.96
Pea	6.51	6.19	6.96	7.26	8.31

Through the latter part of the year the whole question of distributing the increased quota was much tangled. There seemed no settled policy and awkward questions were not answered. Retailers inland were generally better supplied than in 1917, but at tidewater ports there was much confusion over the grouping of figures. Distribution had never been absolutely restricted to town lines, and where so much was built upon 1916 deliveries there should have been better comprehension of local conditions.

In August, ostensibly to reduce the towing distance, Reading barges began to load at Port Reading, N. J., instead of at Port Richmond, Philadelphia. Later this was the rule, only barges from the Port Richmond repair yard clearing from Philadelphia. The order to do this issued from the Railroad Administration at Washington, but in the judgment of those longer familiar with such problems the result was a loss, not a gain. Reduced tug mileage was not the whole story. The general lack of facilities at Port Reading, the fact that barges of that size can only pass through Hell Gate on a daylight tide, and the storing of cars in a most congested area, are only some of the reasons that readily occur. The records show that it has taken as long to reach Cape Cod from New York as from Philadelphia, and one would suppose the experiment would soon be brought to an end. The repairs occasioned by barges bumping into each other at Port Reading should alone be reason enough for abandoning the innovation. The whole Reading organization is geared to handle these barges from Port Richmond.

A distinct falling-off in receipts early in the fall led to special requisitions of egg, stove and chestnut to

be distributed by the New England Fuel Administration from the New England gateways. The original provision was for 50 cars daily; but when this mark was not reached the order was increased to 100 cars per day to make up arrears. The "independents" had been making no better shipments, and because of this the companies were struggling not only to meet their own obligations but to ship the extra tonnage piled on them by the Anthracite Committee, usually to make up the deficiencies of "independents."

The "free coal" for New England was to be more equitably distributed than was assumed possible through trade channels. The program was for each retail dealer applying for coal to send his check in advance to the New England Fuel Administration and bind himself to accept whatever size was sent him, regardless of preference. In other words, it was "anthracite," no distinction being made as to size or grade or price. A lot of dissatisfaction followed, naturally, and gradually the order was reduced, chiefly through the inability of the fuel authorities to dispose of it. At the end of the year it was dropped to five cars daily. While "free coal," egg, stove, and chestnut was being worked off in this manner, state fuel administrators frequently soliciting consignments, the regular coal factors were placing the surplus broken and pea that the New England Fuel Administration did not want. The bulk of the "free coal" was furnished by shippers of whom less complaint could be made, and it was granted to make up the arrears of shippers who were justly complained of.

Shippers with established connections had a favorable year, on the whole. A heavy tonnage of buckwheats helped make up deficits in the tonnage of domestic sizes. Retail dealers, on the other hand, passed through an extremely trying period. Too much in the way of regulation was attempted and a too finely graduated measuring stick was used too often and for too long a time. But out of it all have come benefits. Dealers know more about accounting; and so does the public about costs! It has been shown what happens when an outside impartial authority steps into the coal business to regulate it. And credits are better.

Anthracite figures for 1918 are misleading, unless they show clearly the large tonnage of junior sizes shipped into New England, especially during the summer, to help make up the shortage in bituminous. At times the movement of buckwheat, rice, barley, and culm reached 35 per cent. of the anthracite total. Beginning in the summer there was more discrimination between grades than last winter, when so much "fireproof" was poured into this market, and by October the movement had sagged to less than 16 per cent. Considering that the use of these coals was new to most steam plants, and that it was difficult to get improved stokers suited to the purpose, New England, from a conservation standpoint, shows a good record in this respect.

At the present time the rate on general merchandise shipments to England from New York is $2.50 per cubic foot of ship space, or $100 a ton, against a high record rate during the war period of $6 per cubic foot, or $250 a ton. The pre-war rate on this class of business was 25 cents per cubic foot, or about $10 a ton.

Pittsburgh District in 1918

By B. E. V. Luty
Pittsburgh, Penn.

The Pittsburgh coal district had a history quite its own in 1918, the war placing special responsibilities upon it. In the first place, the district normally serves a large part of the iron and steel industry, not only as to the production of iron and steel, but also as to its fabrication into various finished products, and nearly all the large machine shops of the district were converted into munition factories. In the second place, the burden of the lake coal movement to the northwest fell unusually heavily upon the Pittsburgh district, because of the heavy demands of the Navy for the smokeless coals of West Virginia and Kentucky. In midsummer the Pittsburgh district was suddenly called upon to "help out" in the matter of lake shipments and furnish a much larger tonnage than had originally been set down as the district's quota.

River Traffic Makes a Spurt

The Monongahela River coal traffic, which had been rather a decadent affair for years, as the outcrops on the river had been worked back as far as was feasible, took on new life in 1918 and materially helped to curtail the scarcity of coal, means being found to bring coal by rail short distances to the river. From a tonnage standpoint, however, the most important development along this line is that by which many mines in the Connellsville region, hitherto serving their beehive ovens, have had their facilities rearranged so that they can ship Connellsville coal by water to byproduct coke ovens in the Pittsburgh district, particularly the 640-oven plant of the Carnegie Steel Co. at Clairton. The Jones & Laughlin Steel Co. ships large quantities of coal from its mines on the Monongahela River to its beehive ovens at Woodlawn, on the Ohio River, and many mills along the rivers receive gas and steam coal by water.

Labor conditions in the Pittsburgh district in 1918 were on the whole relatively satisfactory. Almost all through the year there was a shortage of labor, but it was due more to depleted forces than to slackness on the part of the men remaining on the payrolls.

Traffic conditions in the first two months of 1918 were indescribably bad, coal production being greatly interfered with by "car shortage," which of course did not mean that there were not enough cars, but that they did not make their round trips fast enough. If there had been fewer cars in service it is possible the daily supply at mines would not have been less. In the spring the cars began to move better, and some cars belonging to the region, blocked all winter in the east, returned to their usual occupation.

The general policy of the Fuel Administration, that coal consumers should stock up during the summer, could not be carried out with respect to the Pittsburgh district, because the coal could not be spared. On account of the heavy demand for lake coal, particularly toward the close of the season, the local coal distributor was required to shut off coal to consumers caught stocking it, and at times consumers were encouraged to draw upon stocks previously accumulated. Toward the close of the lake season a shortage in domestic coal developed, and the lake market seemed to be in fair way to be

well supplied, so that a slight diversion of coal from the lake trade to the domestic trade was permitted.

The year opened with Government prices for the district at $2.20 for slack, $2.45 for mine-run and $2.70 for screened. In the spring, when the arrangement was made that railroads should pay the full prices, the Government limits were reduced 10c. This was better for the operators than for the higher prices to obtain on most trade, with the railroads paying the much lower prices the Railroad Administration had had in mind.

With the signing of the armistice Nov. 11 and the general slowing down in industrial operations, Pittsburgh district coal did not become nearly as plentiful as was the case with coal in many other districts, particularly Ohio, Indiana and Illinois. This was due chiefly, no doubt, to the fact that very little Pittsburgh district coal had been stocked, but operators in the district were disposed to contend also that their coal is better and that when consumers were again given a choice they were disposed to take Pittsburgh coal. Another factor was the demand for gas coal, which hardly let down at all, and a large portion of the district's output is of that variety. The result of all this was that even in the closing weeks of the year some gas coal consumers were willing to pay dealers the Government brokerage allowed, in addition to the set price, while there was very little steam coal sold at less than the set price, concessions as a rule being merely in the form of producers allowing a margin to dealers, so that they could sell to consumers at the regular Government limit.

That coal prices will recede somewhat seems very probable to leading coal operators in the district, but the operators contend that there will be less decline in the district than in the majority of the districts, and that if lake demand proves fairly good in 1919 the district's output will be absorbed fairly well.

Prosperity Insured if Capital and Labor Co-operate

By John H. Jones
President Bertha Coal Co., Pittsburgh, Penn.

Our country is facing the greatest era of permanent prosperity known, providing the people coöperate to bring about such a condition. Capital should give intensive thought to the problem and render to labor the highest returns possible in payment for labor performed. Labor in turn should coöperate with capital, permitting capital to receive fair returns on its investment, keeping in mind the constant and steady employment of labor and capital.

Through such coöperation we will be kept constantly busy; growing and moving crops to feed other countries as well as ourselves. This will require coal, steel and other products mined and manufactured. Labor will be employed steadily on a large scale, and the resultant prosperity of the country will be in direct proportion.

The time necessary to bring about this condition will depend upon the teamwork of employees and employer. Leaders of labor should advise their following carefully and not intimidate capital by trying to impose unfair conditions. Capital must study conditions carefully and pay the highest wages possible, consistent with good business, and in all cases, keep in mind the cost of living, as labor is worthy of its hire and should receive its share.

During the present adjustment period coal will be plentiful, but within a few months when industries are operating to their full capacity it will require every effort on the part of the miners and operators to supply the demand.

More coal will be required in 1919 than in any year in the history of the world. The railroads alone will use 200,000,000 tons. Potteries, glass, cement and so-called non-essential industries will require much more coal than during any year of their existence.

We, as American citizens, must urge our statesmen to pass such legislation as is necessary to have employers agree on a selling price for their product under the supervision of the Government, so that they will be able to pay labor the highest wages possible and at tht same time receive a fair return on their investment. By so doing we will stabilize business, preventing either a destructive minimum, or a prohibitive maximum. If such condition is not brought about, we will have two extremes in selling prices in the year 1919.

Coöperation will sustain confidence; confidence will stabilize business; and business stabilized will bring prosperity and happiness.

Output of South African Coal Mines in 1917 Shows Increase Over 1916

The annual report of the Government mining engineer of the Union of South Africa for the calendar year ended Dec. 31, 1917, gives the following tabulation of coal mined for the years 1916 and 1917:

Province	Coal Mined Short Tons	Coal Sold Quantity Short Tons	Coal Sold Value	Coal Sold Per Ton
Transvaal	6,936,418	6,641,229	$7,724,121.94	$1.16
Cape	11,510	8,300	28,976.50	3.49
Orange Free State	897,654	843,095	1,058,212.04	1.25
Natal	3,103,604	2,890,296	7,140,900.48	2.47
Total in 1917	10,949,186	10,382,920	$15,952,210.96	
Total in 1916	12,281,796	10,007,502	13,342,168.55	

The variation in the price is due to competition rather than to the great difference in the quality of the coal. The following table gives information about the number of coal-mining machines in use in the Union of South Africa for 1916 and 1917:

	NUMBER OF MACHINES			
Province	Electrical	Compressed Air	Total	Percentage of Work Done to Total Tonnage Mined by Collieries Using Coal Mining Machines
Transvaal	6	382	388	31.47
Cape	..	...	...	.....
Orange Free State	..	15	15	34.93
Natal	22	162	184	56.78
Union of South Africa, 1917	28	559	587	71.21
Union of South Africa, 1916	20	517	537	75.82

In 1917 there was a decrease in the percentage of coal mined by machines compared with that similarly produced in 1916; this was due to the fact that the total tonnage mined by such collieries increased in 1917 by some 11 per cent. over the previous year. The total number of employees in the coal mines of all the provinces of South Africa in 1917 was 1463 whites and 30,025 (55 female) colored workers.

Detroit Coal Market in 1918

By E. E. DUNBAR
Detroit, Mich.

WITH many of its residents experiencing hardship and suffering because they were unable to obtain coal, Detroit welcomed the coming of 1918 with reservations. In the twelve months that have intervened, more than in any previous year in the history of the city, public interest has centered about the coal trade and problems of coal supply. For consumers and dealers, the greater part of the year has been a period of anxiety, uncertainty and strain, with the confusion at times seemingly heightened rather than alleviated by mandates and regulations put out by the Federal and state fuel administrations.

Detroit's visible supply of anthracite when the year opened was virtually limited to the cargo of the lake freighters "B. F. Berry" and "R. J. Reiss." Ice conditions had prevented delivery of the coal at the upper lake port that was their destination. Shortage in supply was aggravated by a condition of railroad congestion that permitted delivery of only a few cars daily of either anthracite or bituminous. One consignment of twelve cars was two weeks en route from Chauncey, Ohio, to Monroe, Michigan.

So serious was the situation that early in the year it was reported 3500 homes in Detroit and its environs were without fuel supply or had only sufficient fuel for one or two days. Heatless street cars were an incidental feature. The coal supply was so low that even the operation of cars became uncertain, while for a time the companies supplying the city with electric light, power and gas were daily facing the probability they would have to suspend operations within a few hours.

Gas and Electric Plants Kept Running

Fortunately for the people of the city, whose inability to get coal was adding to the burden of the gas and electric companies, these utilities were kept in operation, the efforts of the coal trade and fuel administration procuring small supplies of coal to keep the plants running from day to day.

The hardships of the public and the difficulties of the dealers and transportation men were increased by a long stretch of near zero weather in January, the temperature one day dropping to 16 below, a degree of cold practically unprecedented in Detroit.

In the endeavor to make the small supply of coal at hand go as far as possible the Detroit police department undertook supervision of distribution to domestic consumers, receiving applications, making small allotments and communicating the orders to such of the dealers as had coal. It was reported early in the month that the yards of 19 retailers had closed, their owners being unable to get coal and unwilling to meet the frantic appeals from customers.

Attempting to curtail consumption, reductions were made in the city's street lighting and the routes and manner of operating the street cars were altered. Edgar B. Whitcomb, then chairman of the Wayne County fuel committee, announced that priority should be given domestic consumers, with public utilities also taking precedence over factory requirements. His appreciation of the coöperation of local dealers during the crisis was demonstrated in his making public an "honor list" showing 129 dealers had filled 46,685 applications, while five dealers had served more than 2000.

With the purpose of bringing about equitable distribution of coal coming into the city, and with the approval of Mr. Whitcomb, the Detroit coal pool was organized by a number of dealers and opened for business Jan. 11, with Edward J. Parks, an experienced traffic man, as manager. Operating in conjunction with similar organizations in other cities, the pool was continued until about the middle of February. A freer movement of coal had then developed and the pool was dissolved. Its operation brought criticism from some of the retailers that their shipments were held back by being put through the pool. Some of the steam-coal buyers complained also that the coal sent to them was of less desirable grade than the stock shipped under their contracts with the mines.

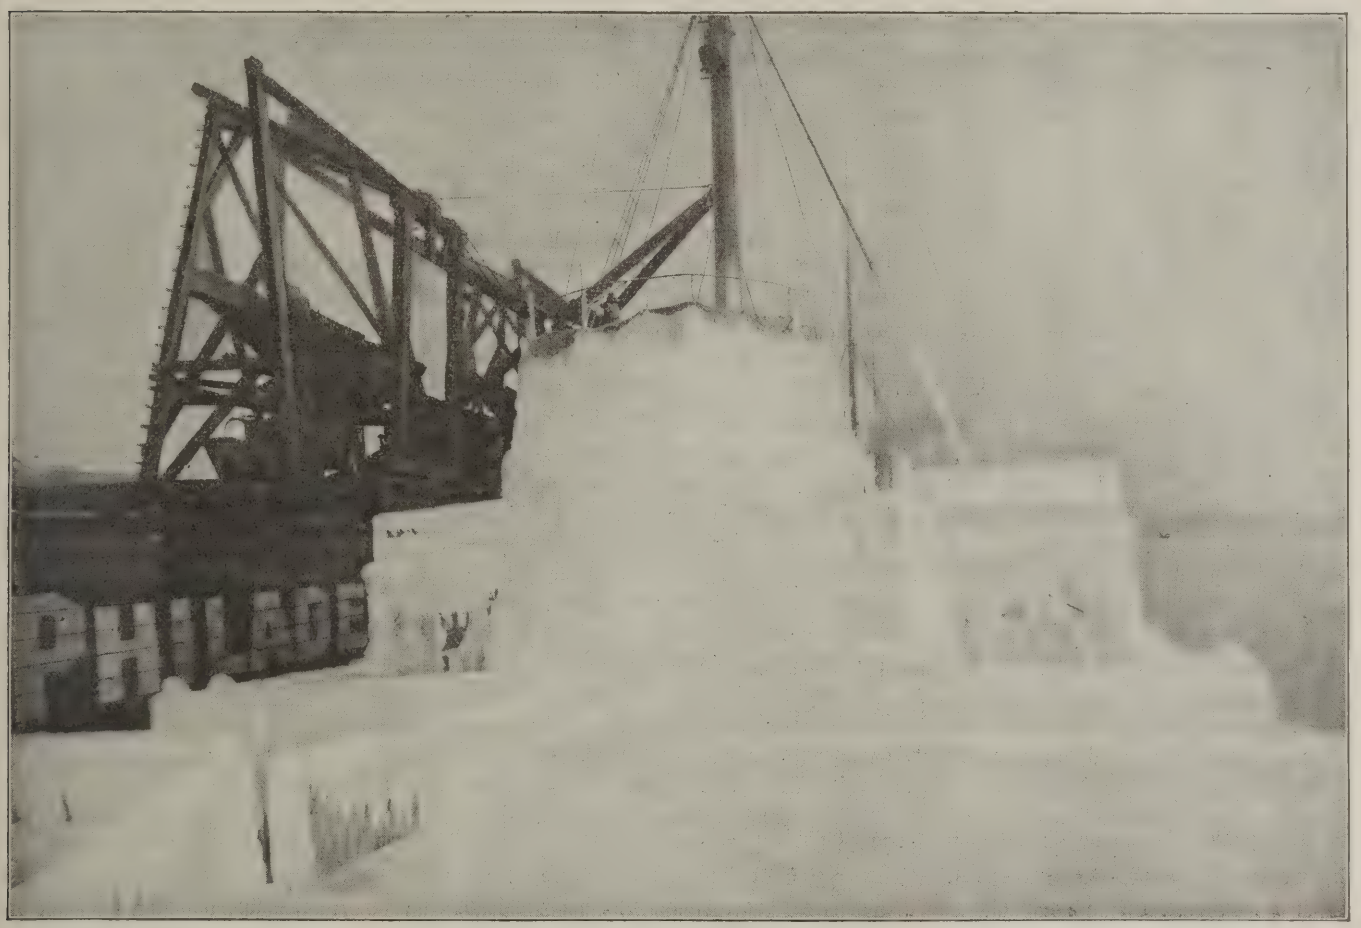
Enforces a Nine-Hour Workday

On Jan. 15, 1917, W. K. Prudden, Michigan's fuel administrator, issued an order making nine hours the maximum business day for practically all mercantile places, office buildings and most other business establishments. This was followed by the Federal Fuel Administration's order for five days shutdown, which threw about 200,000 Detroit workers into idleness.

Because of their having exhausted coal on hand and their inability to renew their supplies, thirty Detroit factories were reported on Jan. 24 to have discontinued operation, while others, including some of the largest in the city, were said to be facing the necessity for similar action.

Considerable friction between Detroit and the state fuel administrator developed about that time, due to reports that Mr. Prudden was diverting to other parts of the state coal that was consigned to Detroit. The dealers also were complaining of the unprecedentedly heavy losses incurred from coal cars being raided by thieves on tracks in the city. One dealer reported receiving a car containing 300 lb. that was billed to him at 38 tons.

The local situation had improved little in early February. Some of the local industrial plants working on war supplies were reported closed, and on Feb. 5 it was announced 54 retail yards were closed because their owners were without coal. On Feb. 6, the public schools of Detroit were closed. They did not reopen until Feb. 18.



Events during the early weeks of the year apparently were shaping toward elimination of the jobbers as factors in the coal trade. Cognizance of this situation was taken in a meeting of the manufacturers and jobbers with the state fuel administrator in Detroit in March, when a number of prominent manufacturers expressed the sentiment that jobbers are a necessary adjunct, performing efficient and valuable service for their cus-

tomers. Protest also was voiced against the zone system, which the Federal Fuel Administration was reported to be outlining and which the Detroiters feared would cut off their supply of coal from West Virginia and Ohio, substituting the product of Indiana mines. W. B. Horne, an agent of the Federal Administration, while in Detroit about that time, announced Detroit consumers would receive no smokeless coal and might get little or no anthracite. As practically 95 per cent. of the domestic trade depends on anthracite, the announcement occasioned much gloom.

Another controversy between Detroit dealers and the state fuel administrator developed in May, when Mr. Prudden announced the gross margins permissible to dealers supplying domestic trade. Mr. Prudden made the population of various towns the basis for determining the margin for dealers in those towns. His first announcement gave Detroit dealers a margin of $2.25, which was later raised to $2.50, but still fell short of the amount the dealers sought.

Dealers contended they could not do business on a margin of $2.50. The Detroit Board of Commerce intervened in the matter, with the desire to effect an arrangement which would speed the movement of coal to Detroit. After an extensive investigation of dealers' costs, the Board of Commerce recommended that Mr. Prudden fix the margin at $2.50 a ton on anthracite and $3 a ton on bituminous. Though he was understood to have approved the investigation, Mr. Prudden apparently disregarded the recommendation, retaining $2.50 as the margin on anthracite and disposing of the allowance on bituminous by fixing maximum prices for delivery of high and low grade coal of that type.

In July the Board of Commerce again undertook to accelerate shipments of anthracite by appointing a special representative to be stationed in Washington. As neither the state nor the Federal Fuel Administration accorded recognition to this agent, his work was soon terminated. The Board of Commerce, however, continued its interest and on Aug. 14 sent a delegation of prominent business men and manufacturers to Washington. The delegation was accorded hearings before representatives of the Fuel Administration, the War Industries Board, Secretary of War and other branches of the Government, without, however, being able to obtain any increase in the city's allotment of anthracite. The allotment of 601,000 tons was a reduction from the amount actually shipped into the city in 1917-18, when coke and smokeless coal also were used extensively as substitutes, while the 1918 allotment to the state represented a reduction of 24.42 per cent.

LAST COAL BOAT OF THE SEASON AT ONE OF THE LAKE DOCKS

Though unable to obtain a larger allowance, the Board of Commerce committee was promised steps would be taken at once to immediately expedite shipments under the city's allotment and to increase the supply of a good quality of bituminous coal. This assurance was followed by modification of the zone regulations permitting shipment of Kentucky, West Virginia and Ohio coal into lower Michigan for the use only of domestic consumers, gas or byproduct plants and railroads. The priority regulations covering shipment of coal from these districts for the lake trade served as a check on

shipments of domestic lump and prepared sizes to Detroit and the most immediate outcome of the order was the cutting off from Detroit steam-coal users of the coals most favored in their operations. To offset this loss, shipments from certain districts of Indiana and Illinois were increased. Fearing they would be able to get no other supply, the consumers of steam coal and many of the retailers accepted the advice of the fuel administration and stocked up heavily with the Illinois and Indiana coal. Both classes of buyers are reported to be having much trouble disposing of this stock.

Prior to the modification of zone regulations described in the foregoing, the Federal Fuel Administration had aroused vigorous protest in Detroit by cutting off shipments to Michigan from the Kanawha and Coal River districts of West Virginia, from which Detroit in normal times is said to receive about 2,500,000 tons of coal annually.

Throughout the first half of the year, the feeling that the state fuel administrator was discriminating against Detroit or at least not giving the attention to the city's needs that circumstances seemed to demand, was growing and differences also were developing between the state fuel administrator and his representative in Detroit, Edgar B. Whitcomb, chairman of the Wayne County fuel committee, the latter's support of the Detroit retailers in their appeal for a higher margin apparently widening the breach.

Mr. Prudden on June 7 requested Mr. Whitcomb to resign. The latter took no immediate action. Detroit coal men, the Board of Commerce, common council of the city and various other local organizations rallied to the defense of Mr. Whitcomb. Their efforts to bring about the dismissal of the state fuel administrator were unsuccessful, as was also the attempt to have Wayne County detached from the remainder of the state as a separate fuel administration district with Mr. Whitcomb in charge. Mr. Whitcomb finally retired, and Mr. Prudden, on June 13, appointed as his successor James Couzens, then Detroit's police commissioner, who with Charles A. Dean had been associated with Mr. Whitcomb on the Wayne County fuel committee. After some opposition had been expressed to Mr. Couzens' acceptance of the appointment, matters quieted down. Mr. Couzens, having received the Republican nomination for mayor, retired from the committee in September. As Mr. Prudden had decided to move his headquarters from Lansing to Detroit, and actually did so Oct. 7, no successor was named for Mr. Couzens. His resignation was said to have been influenced by a desire to give undivided attention to the campaign which resulted in his election for mayor of Detroit.

In the effort to obtain definite information on Detroit's anthracite needs the state fuel administration set apart the first ten days of September for receiving applications from domestic consumers dependent on hard coal base-burners. Some 23,000 applications were listed. With those previously submitted to dealers the total is estimated at 53,000. The allowance of anthracite, originally fixed at six tons each, was subsequently reduced to a maximum of four tons.

The closing weeks of the year were featured by an inactive market for either steam or domestic bituminous, due to the large stocks held by many of the steam plants and retail dealers. In the case of the dealers distribution was impeded by the fact that mild weather continued practically without a break to the end of the year, and also by the fact that much of the coal in dealers' yards is better suited for factory use than for household heating plants.

Many of the dealers are apparently confident that removal of zone restrictions and retirement of the various fuel administrations will make possible a smoother and more satisfactory operation of their business during the coming year than was experienced in 1918.

Toronto Coal Trade in 1918

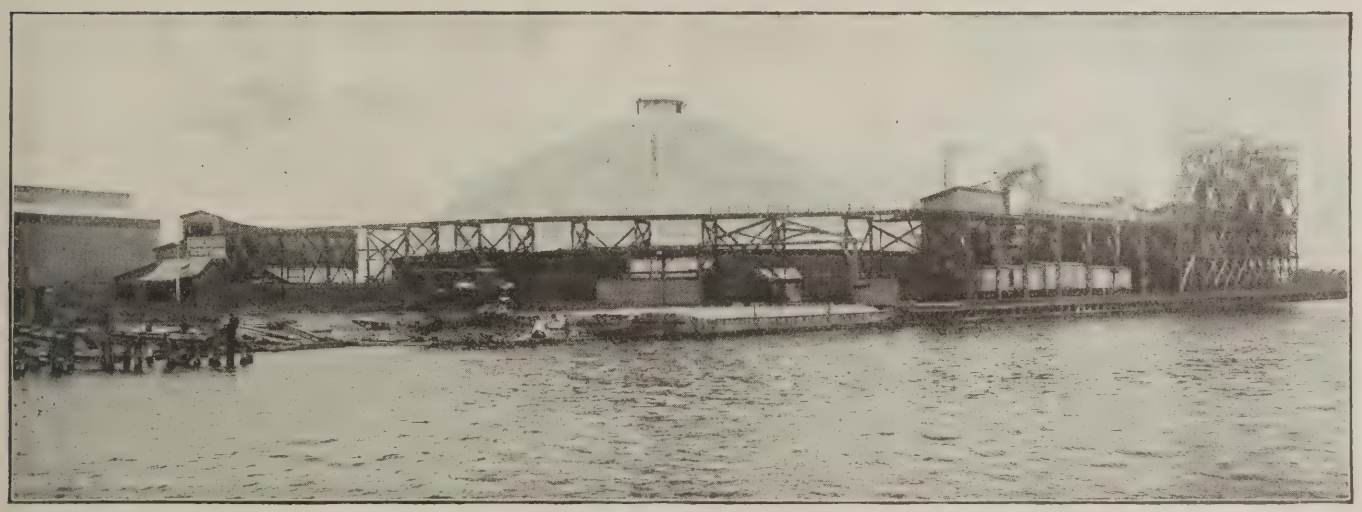
By Phillips Thompson
Toronto, Canada

The coal market during the earlier months of the year just closed was characterized by a great shortage in the supply of domestic fuel. The yards were empty and deliveries light, and dealers only filling orders in small lots to supply immediate requirements. This condition of affairs was aggravated by severe weather and the difficulty of obtaining help.

With the opening of spring dealers were overwhelmed with orders from consumers, who, warned by the experience of the previous season, were anxious to lay in supplies early, as they were urged to do by the Fuel Controller. The usual practice has been for the larger consumers to give their orders and arrange for deliveries from time to time as required, but last year nearly every householder requested immediate delivery of his year's supply. The consequence was that dealers were in receipt of orders which would keep them busy for months ahead.

Deliveries were made direct from the cars and very little coal stored in the yards. The difficulty of distributing the supply was much increased by labor shortage, which continued until late in the fall. The taking of orders was suspended from time to time in order to enable dealers to overtake delayed deliveries. These conditions induced a general feeling of apprehension on the part of the public and an impression that a serious shortage in the supply prevailed. That this was unfounded is shown by the figures furnished by the Fuel Controller giving the total shipments of domestic anthracite received in Toronto for the year ending Nov. 30, at 417,156 gross tons, as compared with 428,000 gross tons for the previous year.

The receipts of bituminous during 1918 considerably exceeded those of 1917. The total consignments to the port of Toronto from April to the end of November were 1,001,709 net tons, as compared with 867,836 net tons during the corresponding period of 1917; but these figures cover the supplies for an area within a radius of about 60 miles round Toronto. Owing to the greatly increased demand for industrial consumption, there was at times a pronounced scarcity of soft coal, but toward the close of the year the market was overstocked with it and prices fell somewhat below the rate fixed by the government.



The general feeling in the trade as to the prospects for business during the new year is decidedly optimistic. The domestic trade is rapidly getting back to normal conditions. All danger of a serious shortage during

the remaining winter months is believed to have been averted by the limitations imposed by the Fuel Controller. Owing to the fact that so large a proportion of consumers have their winter's supply stored in the cellars, the domestic trade is likely to be lighter than usual for some weeks. As soon as the season opens an increased volume of business as compared with the last few years may be expected, as with the return of the soldiers from overseas many new homes will have to be provided for.

The demand for industrial coal which is at present quiet, is dependent upon the reconstruction of industries upon a peace basis, and while the future cannot be forecast with any degree of certainty, there seems every likelihood that the present year will witness great activity in the staple lines of manufacturing. A large number of the workingmen displaced by the closing down of the munition plants in Toronto have already been absorbed by shipbuilding, agricultural implement, tractor and other industries. Many new enterprises are projected in view of the opportunities presented by the export trade, and though the process of getting down to a peace footing is necessarily somewhat retarded by present high cost of material and labor, in view of which some contemplated undertakings are being temporarily delayed, it is regarded as assured that the heavy domestic and foreign demand for the staples of production will insure a busy and profitable season for the manufacturer, and a resumption of activities means a strong demand for fuel.

Buffalo Coal Market in 1918

By JOHN W. CHAMBERLAIN
Buffalo, N. Y.

LEHIGH COAL SALES CO. DOCK AT SUPERIOR, WISCONSIN—NOW BEING REBUILT

AS BUFFALO is a jobbing bituminous market it was hit hard by the conditions in 1918. Only here and there did a jobber do anything like an active business, while not a few of them confess that they did not make a living. The reason for this is plain. Unless there is a surplus of coal most operators sell their output direct to consumers. The jobbers knew this well, and though they complained, they clung closely to the office routine and waited till the old conditions should return. Only one or two suspended entirely. James A. White did practically no business and finally closed his office and went away. Harry F. Butler kept the office of the Century Coal and Coke Co. open, but did no business there. The company could sell coal in Montreal, and it did so. Both of these offices expect to reopen this year.

Never did the bituminous trade change front with the rapidity it assumed last November. While the experts were still crying that coal was to be scarcer than ever before, it began to become plentiful and almost in a day it overflowed; first in Canada, keeping the Buffalo jobbers in hot water paying demurrage, and then in general, with most of the members of the local trade still with their feet on the desk, waiting for the producer who would sell to them. From all sides salesmen reported that the consuming yards were piled full, and yet the jobbers had sold but little of this coal and had made next to nothing out of it. Before the end of the year there were salesmen here, offering coal from territory not before tributary to this market.

The future of this trade is a problem, for nobody knows what can be done with the increase of bituminous capacity created by the war demand, and said to be at least 25 per cent. more than it was. Will home industry and export take care of it all? The Buffalo jobber does not see how this can be done. While everyone is hopeful, and is prepared to make the fight for all he is worth to regain his suspended tonnage, it is no exaggeration to say that if this new capacity cannot be shut off somehow, the bituminous trade will go back to the control of the consumer, where it was before the fall of 1916. This means selling on a 10c. margin and producing at about cost.

Buffalo is not a jobbing center only. A big tonnage passes through this city that is not even sold here. There is a good producing tonnage here also. About

an even dozen companies, with offices in Buffalo, last year turned out 2,631,867 gross tons of bituminous coal and there is good prospect of more this year. Capitalists spent good money last year, looking for mines that they did not find, and they will resume the quest when the trade settles down a little.

Buffalo ships about four-fifths of the anthracite in the lake trade, sending it all to ports on Lakes Michigan and Superior. Some is still shipped from Erie, Penn., but the ports of Lake Ontario have dropped the upper lake trade for the present. The amount of anthracite shipped from Buffalo by lake in 1918 (customhouse figures) was 3,594,803 net tons, as against 4,237,904 tons in 1917. The operations were on an allotment prepared and enforced by the general anthracite committee, which maintained W. C. Blodgett, an old anthracite man, to look after it. As the season neared its close it was found that the shipments were behind the allotment, but an extra effort was made and the amount was moved.

This rush of anthracite to the lakes late in the season kept the city supply very short and complaints were many, though no actual distress was reported, thanks largely to the activity of the local fuel administration office. Late in the year even the anthracite demand became easier. December beheld the fuel administrator's office announcing that the supply would be normal by Jan. 10. The fuel office had now nothing to do! The sudden change of front in anthracite was largely due to the warm season. The year went out with the thermometer up to 50 deg. Only about 20 days had shown freezing temperature, the lowest being 19 deg. But for a bad shortage of natural gas, the situation would now be of the best.

Milwaukee Coal Trade in 1918

By HERMAN BLEYER
Milwaukee, Wisconsin

THE story of Milwaukee's coal market in 1918 is devoid of anything of unusual interest. Dealers agree that it has been satisfactory in every way, but much will depend upon weather conditions during the remainder of the season. The winter thus far has been mild and with little snow. With prices fixed for both wholesaler and retailer by the Fuel Administration, and with restrictions as to delivery, the coal business of the year thus far has lacked every element of marketing and lapsed into a routine of simply keeping things moving.

The closing months of last winter were unusually bitter, and storms retarded deliveries for weeks. With the tribulations of that period in mind, coal handlers entered the new season on Apr. 1 with a determination to get in all the coal they could as soon as possible and to hasten the output to consumers in every possible way. The westward movement by lake began alarmingly slow, but by persistent effort on the part of dockmen the flow was accelerated to such an extent that when navigation on the Great Lakes closed the docks in Milwaukee harbor held full supplies of bituminous coal and all the hard coal that had been allotted to the district by the administration.

Summer deliveries were made on an unusually large scale both to manufacturers and householders, the

UNLOADING A BIG STEAMER—TYPICAL SCENE IN THE MILWAUKEE COAL DISTRICT

SHIPMENTS OF COAL BY RAIL OUT OF MILWAUKEE DURING 1918

	Hard	Soft
January	12,727	97,801
February	16,458	80,521
March	12,313	76,676
April	1,978	38,052

Total, 1917	200,465	772,770

former, in many instances, accumulating large stock piles in the vicinity of their plants. The signing of the armistice between the warring nations was followed by an almost complete cessation of orders from the larger consumers, however, and business has been dull ever since.

Prices of all grades of coal ruled high during 1918, but consumers accepted the situation gracefully, and were seemingly satisfied if they got the supplies they needed. Federal regulation has proved popular. Small dealers say the Government has treated them very fairly, and in so doing has helped the big fellows to a better profit. There is no complaint on this score. Regulation has stabilized business and taught some valuable lessons as to cost of doing business. It has also brought dealers together and wiped out little burdens accumulated during years of keen competition. Opinion is unanimous that regulation should be continued at least until the end of the coal year in spring, as stocks have been purchased on the basis of schedule prices, and the entire business directed in accord with Administration rulings. Were regulation to be suddenly withdrawn, there would in all probability be a slump, which would be disastrous to those with large stocks bought at war prices.

Everybody in the coal trade at Milwaukee predicts a prosperous new year and are facing the future with a feeling of optimism. They base this judgment on the ground that every industry will be taxed to its utmost to supply things needed to make up for the wanton destruction during the war, and that factories will demand maximum supplies of fuel. It is expected that the policy inaugurated by the Government of stimulating the production of Illinois coal will make producers in that section livelier competitors in the Milwaukee field in future, as many who had never used western bituminous before have become wedded to it. Whether this will be so when Government restrictions are removed is problematical.

Ohio Coal Trade in 1918

By J. W. Lehman
Columbus, Ohio

The year 1918 was a most peculiar one in the coal trade in Ohio territory. It differed from any preceding year in the fact that the change from a strong market to a rather weak demand, which took place during the closing weeks of the year, was probably the most rapid transition in the history of the trade. Of course, the usual events brought out by the world war were something without precedent, and consequently the striking effects of the signing of the armistice were without precedent.

The year, with the exception of the final five or six weeks, was one of the most prosperous in the memory of coal men in Ohio. This is especially true of the producing end of the business, which was running at high speed throughout the year and which reports an output far in excess of that in any previous year.

An analysis of the market conditions which prevailed during the year reads similar to many other lines of business, with the exception that the decline was probably more rapid than that experienced in other lines of endeavor. The year opened with an exceptionally strong demand, not only for steam, but also for domestic grades. This continued pretty much throughout the year, and every one was at top speed, so to speak, until the end came suddenly.

With the opening of 1918, domestic demand probably monopolized the attention of producers, distributors and retailers alike. The railroads were tied up and retailers were clamoring for fuel with which to make deliveries to customers. There was a marked shortage, which was partially relieved by the fuelless days designated by Fuel Administrator Garfield. This condition lasted for the greater part of the winter season and was only relieved by warmer weather.

Due to the efforts of the state and county fuel administrations, suffering among householders was held at a minimum and there were no actual cases of extended suffering.

The steam business during this period was in pretty much the same condition. Steam grades were scarce, and users vied with each other to get deliveries. It was a scramble to get fuel sufficient to operate plants and also to keep the public utilities going. In fact some of the public utilities were put on short fuel rations, in order to help the war program along.

With the coming of warmer weather, which relieved

the domestic situation, there was more fuel for steam users, and little trouble was experienced from that time on. But frequent warnings of the Federal and state fuel administrations caused steam users to continue buying in order to accumulate a surplus stock for the coming winter.

At the same time domestic users were urged to lay in their winter's supply of fuel early, and that helped to maintain the strong demand. When the fall season arrived, a much larger proportion of winter coal had been stocked by householders than ever before. Steam users had thousands upon thousands of tons of coal laid by to guard against emergencies.

Buying continued strong right up to the day of the signing of the armistice. Then suddenly purchasing agents stopped to look around and size up the situation. Retailers who had accumulated large stocks found that as the production at the first of the year, when it was reduced to that level through car shortage and transportation congestion.

As to the outlook for 1919, there is a wide divergence of opinion among producers and jobbers. Generally speaking, however, the larger and more established operators do not look upon the future with many misgivings. They claim that when present steam stocks are consumed and business gradually gets on a peace basis there will be a good steady demand for fuel.

One of the larger operators, who is a prominent member of the National Coal Association, fairly spreads optimism in his discussion of the future of the coal trade in Ohio, as well as in other parts of the country. He banks a great deal on the undoubted foreign demand which is bound to develop with the reconstruction. He believes that the country will recover rather rapidly

MILWAUKEE'S LARGEST DOCK YARD FILLED TO CAPACITY—UPWARD OF 200,000 TONS

the weather was unfavorable for an early moving of their stocks. Many orders were cancelled and the slump started. As time passed, the slump gained momentum until at the close of the year there was a greatly reduced demand for coal. In fact steam grades were almost a drug on the market, as steam consumers were following the policy of using their reserve stocks and were only buying when they had to.

Some price-cutting resulted, but the larger producers continued to hold their product at Government prices. As a result there was no general demoralization of the market. Of course, production was cut under these circumstances, but toward the latter part of the year it was about 50 per cent. of normal, which was about the same from the effects of the world war and that the coal industry will assume a more responsible position than ever before. He believes, however, that there will be a period of slack demand which is inevitable under present conditions. The larger and more substantial operating concerns will emerge in good shape and in a position to go on and improve their status. Those who were pessimists at first have changed their views.

It is true that there was a great spurt in development work in Ohio, as in other coal-producing states, and many of the newer operations were conducted at a high overhead cost. Many of these will fall by the wayside, and the substantial concerns which are operated efficiently and with a low overhead will survive.

Production in Colorado in 1918 and the Outlook for the Coming Year

By F. W. WHITESIDE
Denver, Colorado

ACCORDING to Mr. Whiteside, who is chief engineer of the Victor-American Fuel Co., of Denver, Colo., and a man of broad vision, there is every reason for the belief that this country is face to face with a period of renewed prosperity. Much of the trade that has come to this country from South America and other foreign countries, Mr. Whiteside believes, will be permanent, and he is certain that a vast tonnage of coal will be required to transport all this material and merchandise. Colorado will without doubt receive a fair portion of the increased business in coal and other products, prophesies Mr. Whiteside, as soon as business again assumes its normal activity.

THE coal mines of Colorado during the year 1918 produced over 13,000,000 tons of coal, which is the greatest output in the history of the state. This tonnage was made possible by the efforts of 176 companies operating 223 mines and employing an average of 14,377 men. The previous year the production was 12,515,305 tons of coal, produced by 234 mines owned by 178 operating companies and employing an average of 13,970 men. With the demand for fuel during the year just passed, every possible effort was put forth to bring the production of all mines up to the maximum. The local representative of the Fuel Administration kept in close touch with all the operators and organized a system by which committees were appointed at each mine, consisting usually of six men designated lieutenants. At some of the properties the committees were composed of both local mine officials and miners, at others the entire personnel of the committee was made up of coal miners and others employed in and about the mine. The duties of the committee at each place consisted in keeping in close touch with the men, investigating all absence from work and exhorting each individual to put forth his best efforts toward securing the greatest possible output. While in some localities the result sought was not achieved, in the main a considerable stimulus was given to the men and the result desired was realized to a considerable extent. The average production per man was therefore above that of the preceding year.

The supply of empty railroad cars for loading was not always dependable, and a considerable tonnage was lost on account of the inability to run the mines steadily, arising from the shortage of cars. This was especially true in the northwest portion of the state known as the Routt County district.

Colorado suffered, as has every other state in the Union, from the Spanish influenza epidemic, which caused a situation so serious at some of the properties that work had to be suspended temporarily. At more than one operation the number of men incapacitated exceeded 25 per cent. of those employed. Most of the mines continued to work in spite of the epidemic, but the efficiency of their operation was seriously affected and their production consequently reduced. Profiting by the experience of last winter, when so much suffering and distress resulted from the scarcity of coal, all consumers were urged to stock up during the summer and early autumn months; this advice was followed to so great an extent that at this time the railroads, industrial plants and many private consumers are buying but little fuel and are depending upon their storage supply. This has caused a decline in the demand for coal, especially for the smaller sizes, and a number of operators have been obliged to dump upon the ground all sizes except lump coal. Consequently few, if any, of the mines have been running full time for the past two months.

The weather conditions always exercise a marked influence upon the demand for coal, this being especially true in the lignite districts; it is often said that a cloudy day or even the weather man's forecast of an approaching storm will stimulate this business. As the fall and winter months up to the first of the present year have been unusually warm and pleasant in the regions where this fuel is consumed, the demand for lignite coal has been light, causing many of the mines to suspend operations three and even four days of each week.

Some of the most popular domestic and steam coals produced in the state are shipped from Routt County. The entire business of this district is handled by the Denver & Salt Lake R.R. This line crosses the Continental Divide at an elevation of 11,660 ft. through a land of perpetual snow. Operating this line with its present 23 miles of 4 per cent. grade over the Divide is a difficult proposition. An unfortunate fire destroyed several hundred feet of snow sheds on the summit in November and caused a suspension of service for a considerable period during their rebuilding; furthermore, a serious cave-in in Tunnel No. 16 tied up all operations for over a month, and the production of this territory has accordingly been seriously curtailed.

It is always difficult to predict business conditions with any degree of certainty, even the best or most carefully planned estimate fails in view of the unknown factors which enter into all such calculations. The present lull in activity is but the inevitable pause

which must be expected to come with the termination of the effort we have put forth for the successful carrying on and completion of the war. It is a common human attribute in a time like the present for enterprises and individuals to rest upon their oars waiting to see what is going to happen When the forward movement again begins they join with the rest, and business will again assume its normal activity.

There is just reason to look for a period of renewed prosperity in this country for a considerable time to come, as much structural and building material must be manufactured here.

A great deal of the trade with South America and with countries over the seas which has come to our doors since the beginning of the war will be retained, and a vast tonnage of coal will be required to transport this merchandise and material to its destination. Much of the building and commercial activity which has been silenced during our participation in the world conflict will be again resumed, thus producing a still greater demand for structural supplies.

Numerous adjustments will have to be made with labor during the coming year. Some of these will not be accomplished without strikes and other delays. It is to be hoped that they will not seriously reduce the coal production.

The question of the operation of the railroads is one which will have a bearing not only upon coal production, but upon all lines of business activity. If the management of the railroads again reverts to their original owners there may be a somewhat serious, though temporary, shortage of cars which will, in turn, affect the coal production.

However, when one considers the efficient manner in which the Government has handled the business of waging war, not forgetting the individual efforts put forth by corporations and individuals alike, there need be no serious apprehension felt for any condition that may arise in the event that the Government ceases to operate the railroads, and any ill effect of this transfer to individual control will be of but a temporary nature and will be soon remedied. It must be remembered, however, that during the strenuous times experienced while the country was at war the control of the railroads enabled the putting into effect of the zoning plan, which not only saved thousands of car-miles at a time when transportation facilities were at their worst, but also enabled the coal industry to meet the manifold demands made upon it.

With labor more plentiful and operating conditions more favorable, the coming year should be one of prosperity in every line of industry. Colorado should receive a fair portion of the immense volume of business that seems assured in coal and all other products, and in the coming year should produce 13,500,000 tons of coal.

The Future of the Coal Industry

By F. S. PEABODY
Chicago, Illinois

I FEEL that there can be no doubt that the coal industry must eventually return to the point where natural laws will once more apply. But this must not come too quickly. There must be no massacre of the industry where the slaughter will be indiscriminate.

Just as the Government, out of necessity, created an artificial situation, so must it of necessity see to it that conditions become normal again. When we entered the war the Government found the coal industry contemplating a hill too steep to climb, and lent a helping hand. We must not now be deserted on the summit. We must be eased down the other slope so that there may be no disaster.

But the Government cannot accomplish this if it is forced to deal with an unsympathetic or unorganized industry. Of all the lessons this war should have taught us, the benefit of concerted action is by no means the least. But with the end of Government control, this road will be closed to us because the anti-trust laws will then resume their functioning.

The President is now abroad, ostensibly for the purpose of showing the world that unrestricted competition, as between nations, is no longer possible. But it will exist in our own country, no matter how disastrous the results may be, so long as the Sherman Law is on the statute books in its present form. We must "clean house" so that we may be fit to take our place in the new scheme of world trade.

If the Government will continue its present form of control until the declaration of peace, and then be ready with an anti-trust law so amended as to allow reasonable cooperation among the members of our industry, we can well take care of ourselves, unless we have failed to be impressed by the great lessons of the war. We already have the machinery we need—the National Coal Association, the National Coal Jobbers Association and the National Retail Coal Merchants Association. And when these bodies, working under a new law, have been made thoroughly representative of the industry, provided only that they continue to be harmonious, and will cooperate they can, and should, become the guiding spirit that is needed.

Lacking some such safeguard as this. the future is not pleasant to contemplate.

Connellsville and Byproduct Coke Industries During 1918

By B. E. V. LUTY
Pittsburgh, Penn.

THE Connellsville coke trade was uneventful in 1918 in the matter of market conditions, for it was under Government price control and there were no changes in basic prices. Furnace coke was limited to $6 a net ton at ovens; foundry coke, 72-hour selected, to $7; and crushed coke to $7.30. One change was made during the year, the size of screen for crushed coke being reduced in June from 1-in. to ¾-in. In August a regulation was made limiting the price of clean screenings, over ½-in. screen, gained from old dumps, to $5.50, this material finding its market chiefly as domestic fuel. It is almost needless to say that furnace and foundry coke commanded the full Government limits throughout the year. Screenings declined fully 25c. under the Government limit in December. Operators were unwilling even to allow brokers any commission on furnace coke, and as Government regulations did not, contrary to the case of coal, permit brokers to charge a brokerage to consumers, there was no margin for the broker. In foundry coke the operators frequently allowed brokers a margin of 25 cents.

Operating conditions in the Connellsville coke trade were altogether unsatisfactory throughout the year, but there were wide variations. The great railroad tie-up of the winter of 1917-1918 scarcely affected any industry or region more disastrously than it did the Connellsville coke region, and yet there was scarcely any railroad freight service more important than that of moving Connellsville coke; for on it depended in great measure the pig-iron production, and consequently the steel production of the country, when steel was an essential for winning the war. Practically every ton of curtailment in Connellsville coke meant a curtailment in steel output.

Poor Traffic Conditions Hinder Output

During the major portion of 1916 the Connellsville region shipped an average of over 425,000 tons of coke a week. In 1917 the average dropped, chiefly on account of traffic conditions, to 336,000 tons a week, which was bad enough; but in 1918, up to the middle of February, shipments were less than 250,000 tons a week. Gradually conditions improved until by the middle of the year shipments were running at 350,000 tons a week. The car service was practically satisfactory, but labor was in short supply, and there were heavy drafts upon the coal resources of the Connellsville region in favor of byproduct coke ovens. As a war measure, on account of the byproducts, every effort was made to put coal through byproduct ovens rather than beehive ovens.

In the late months of the year production of Connellsville coke was seriously interfered with by the epidemic of influenza. Many men were attacked, while on account of the scarcity of help many men stayed at home to nurse members of their families who were affected. Inoculation was practiced to a considerable extent and results from inoculation were quite favorable. So great was the curtailment in output that despite the slackening in the iron industry that occurred after the signing of the armistice Nov. 11, there was a distinct shortage of coke and a few blast furnaces were forced to bank at times, while many operated at reduced blast pressures to conserve their meager supplies of coke.

Connellsville Coal for Byproduct Ovens

The time was, but a few years ago, that the typical Connellsville coke operator could not see but that the demand for Connellsville coke would continue until the coal was exhausted. Any suggestion that the coal would be shipped in large quantities for conversion into coke by byproduct ovens was scorned. The thought of Connellsville coal going through a byproduct oven was regarded almost as an insult to the coal. Eventually events proved otherwise, and in no year was there such a great diversion of Connellsville coal to the byproduct coking process as in 1918. This arose from the double effect of the completion during the year of many byproduct ovens directly tributary to Connellsville coal, and the necessity of operating all such ovens in full oven if beehive ovens had to be closed, because the byproducts were needed for war purposes. For a time the shipments of Connellsville coal averaged 250,000 tons a week, chiefly for byproduct coking. This represented about 40 per cent. as much coke as the Connellsville region had itself made in its best days.

The most important single operation in byproduct coking directly associated with the Connellsville region was the Clairton plant of the Carnegie Steel Co. This plant was projected several years before, and it had been expected to get it in operation in 1917; but the first coke was not made until 1918, in which year the whole 640 ovens originally projected were completed, leaving under construction 128 ovens of a second batch of 640 ovens, the construction of which will proceed slowly.

The Clairton operation contemplated complete elimination of rail movement in both coal and coke, the coal to be towed down the Monongahela River to barges, and the coke to be distributed first to the Carnegie Steel Co.'s blast furnaces that are reached by its inter-plant road, and then, as output grew, to be distributed by water to various other Steel Corporation blast furnaces in the Pittsburgh district. Owing to war exigencies the necessary river craft were not altogether available, and there was much rail movement of Connellsville coal to Clairton. As the plant was being operated with particular reference to byproducts, the coal used was chiefly Lower Connellsville, running about 65 per cent. as to volatility, while the old basin coals run about 70 per cent. The normal operation will be more largely with old basin coals.

In the case of the Clairton operation, as with several

other byproduct plants in the Pittsburgh, valley and lake front districts, the byproduct ovens have been built with the direct purpose of supplanting beehive ovens in the Connellsville region, owned by the same interests, so that the same coal will be used, and by the same interests. In some cases coal from other districts will be used to an extent. In one or two instances blast furnace interests formerly purchasing Connellsville coke have built byproduct ovens, and simply buy coal instead. In one notable instance the furnace interest, being in doubt as to the date of completion of its byproduct ovens, made a contract which should automatically turn from coke to coal upon completion of the ovens.

While the war halted much new construction work, it stimulated work on byproduct ovens, the Government being so much interested in the byproducts, and work was pushed despite the great difficulties. As a result, no less than 2085 byproduct retorts were completed in 1918, against 739 in 1917. In ten years previous the average increase had been about 375 ovens per year, but a few more than that were built, as some ovens were abandoned.

Increase in Number of Byproduct Ovens

According to a statement compiled by one of the largest interests engaged in building byproduct ovens under contract, there were 6756 byproduct ovens in the United States at the beginning of 1917, and the 739 built in that year brought the total at the close of the year to 7495. With the 2085 built in 1918 the number on Jan. 1, 1919, was 9580, with 1620 additional either in course of erection or definitely projecting, pointing to a total in the not distant future of 11,200.

The weekly reports of the byproduct industry, compiled by the U. S. Geological Survey for the purpose of stimulating byproduct coke manufacture as a war measure, furnish interesting information as to both the capacity and the output of the industry and indicate the causes of loss of production. The Survey required that each operator report weekly his capacity and production, assigning causes for loss of production—coal shortage, labor trouble, repairs to plant, no market, and miscellaneous causes.

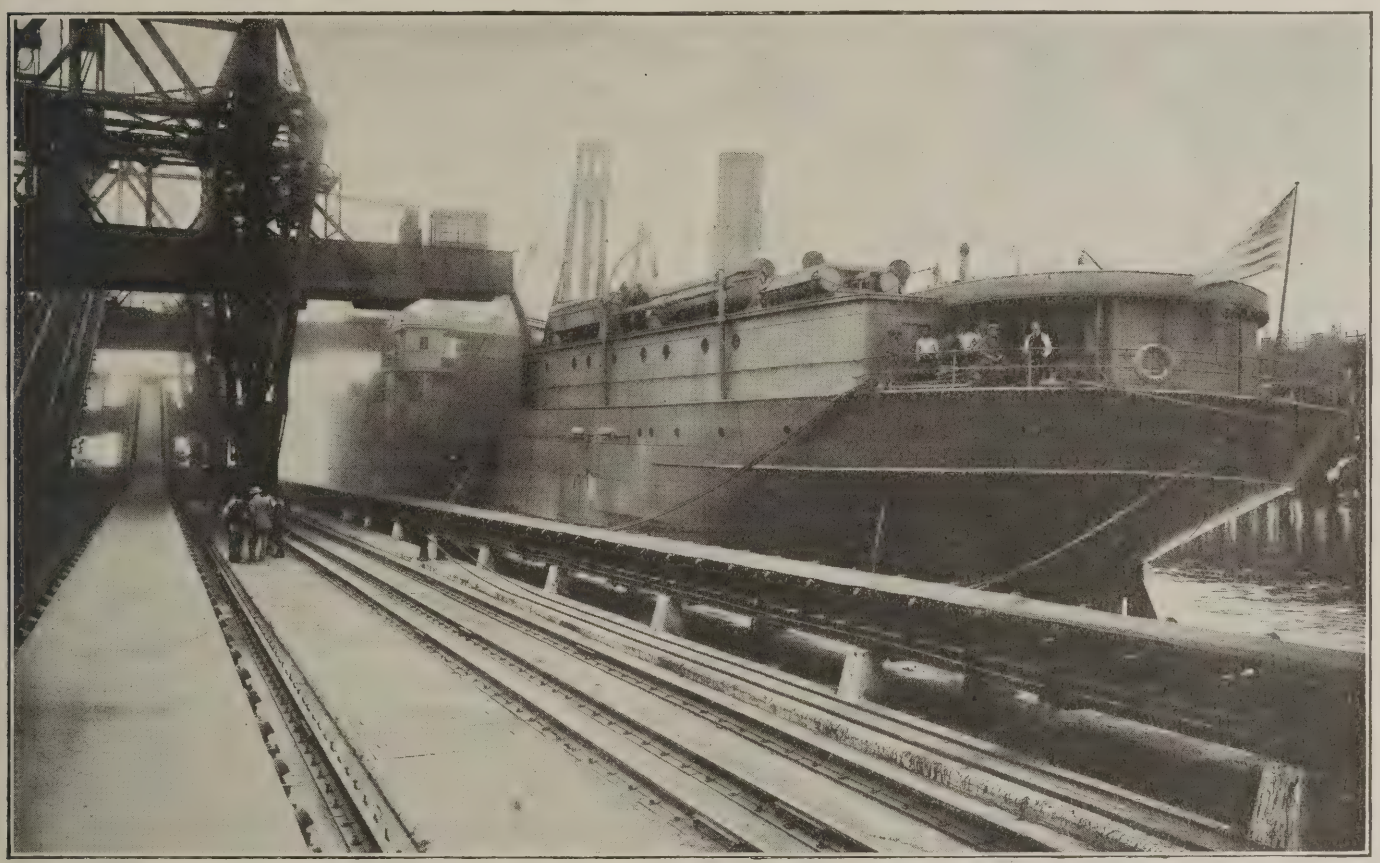
The coke reports of the Survey were instituted at the beginning of 1918, and a study of the reports through the year suggests that as the weeks passed and operators had occasion to assign causes for the difference between rated capacity and actual production they scaled down their ratings somewhat. Their reports at the beginning of the year indicated a total rating for the country—a few plants did not report at the outset—of 500,000 net tons of byproduct coke a week. This agreed exactly with builders' estimates of 26,005,400 tons annual capacity for the 7495 ovens that had been completed to Jan. 1, 1918, while at the close of the year the operators' ratings totaled about 650,000 tons a week, or 33,800,000 tons annually, while the builders' estimate for the 9580 ovens then completed was 35,211,200 tons.

The reports in the early months of the year showed coal shortage as a predominating influence in restricting output, but later, when there was a fairly adequate coal supply, though frequently not of the description of coal the operator would have preferred, plant repairs, occasional labor trouble and miscellaneous causes were so uniformly sprinkled over the weeks that one is disposed to conclude that a reasonable expectation of output is about 90 per cent. of rated capacity. Taking this at 650,000 tons weekly, the actual commercial capacity of the byproduct coke industry Jan. 1, 1919, was about 30,420,000 net tons a year, with more than 6,000,000 tons in prospect through new construction, pointing to an eventual commercial capacity of 37,000,000 tons, the makers' rating of capacity being 42,800,000 tons. These comparisons would be entirely misunderstood if they were taken as suggesting any criticism of either coke-oven builders or coke-oven operators. In this industry, as in many others, "capacity" is merely a standard to be approached as closely as circumstances permit, and the comparisons made suggest how close the approach can be expected to be.

The rapid growth of the byproduct coking industry exceeds the pace at which new blast furnaces, the chief consumers of coke, are built; and as byproduct ovens will operate if necessary at the expense of idleness of beehive ovens, there must be some idleness of the latter. Taking the beehive capacity at 35,500,000 tons, the 1916 output shown in the table having been the record output in the history of the industry, and the prospective byproduct output of 37,000,000 tons, as computed above, there is a total of 72,500,000 tons.

COKE PRODUCTION IN THE UNITED STATES

	Beehive, Net Tons	Byproduct, Net Tons	Total, Net Tons
1893	9,464,730	12,850	9,477,580
1900	19,457,621	1,075,727	20,533,348
1910	34,570,076	7,138,734	41,708,810
1915	27,508,255	14,072,895	41,581,150
1916	35,464,224	19,069,361	54,533,585
1917	33,167,548	22,439,280	55,606,878
918	30,406,000	26,264,000	56,670,000



The possible consumption can be estimated with considerable closeness. In 1916 the blast furnaces produced 39,534,797 gross tons of pig iron and consumed 44,431,905 net tons of coke, which was 80 per cent. of the country's output, the balance being used in nonferrous metal blast furnaces, in iron foundries and for various heating purposes. The present blast furnace capacity is a trifle under 45,000,000 tons, and with the completion of furnaces now under way it will be about 46,000,000 tons. With the blast furnace industry running full, therefore, it would require about 52,000,000 tons of coke, and with this at 80 per cent. of the country's total consumption the total would be 65,000,000 tons, while as just noted there will be capacity to supply 72,500,000 tons. The slack will be taken up by idleness of beehive ovens, and the shipment of their coal to byproduct ovens. This movement, indeed, began long before 1919.

Next to the textiles, mining is the principal industry in Poland, especially that of coal, which was considerable in the years before the war. The quality of coal mined in Austrian Poland is better than in the German portion. Before the war Russia started to open some mines in Poland, but the work was never completed. Under the German military government the work has progressed, although, of course, it is not possible to make the technical installation as perfect in Poland as in Upper Silicia.—*Commerce Reports.*

Northwest Coal Trade in 1918

By W. L. KIDSTON
Seattle, Wash.

WHILE the abdication of crowned heads in Europe last year proved popular with coal operators of the Northwest, as it did with the rest of the country, it cannot be exceeded by the mine owners' great satisfaction in the way King Coal in this section came into his own, or in the knowledge that the coal mines of the Northwest contributed mightily to the overthrow of Autocracy. While no one expresses much enthusiasm over the profits (or lack of profits) to the trade for the past twelve months, mine owners of this district are justified in expressing pride over the records established in keeping production abreast of the unexpected and enormous demands made upon them by transportation lines, shipyards and war industries.

COLLIER "TUCKAHOE" MAKING A RECORD COAL LOADING IN 2 HOURS 50 MINUTES, MAY 25, 1918, AT THE CURTIS BAY (MARYLAND) PIER

And as they express great satisfaction over their achievements during the past year, they are unanimous in the opinion that this will bring its reward in the years to come—with greater production and consumption than ever before, and with more settled labor conditions and more equitable profits, all of which will contribute to the prosperity of the entire trade. Coal-mine operators are agreed that the trade in the Northwest will never again return to the conditions which obtained before our entrance into the world war.

There are many reasons why the coal trade in the Northwest in the future should be more desirable and profitable, but to understand this it is necessary that a brief review be given of conditions which the coal trade in this section formerly operated under.

Previously to last year, the coal trade here had more than its share of competition. Hydro-electric energy in the Northwest in recent years has been developed rapidly, and as time has passed electric power has been sold here cheaper than in practically every other section of the country. California fuel oil has of recent years been a particularly aggressive competitor, and due to its cheapness it rapidly supplanted coal burners in many of the industrial institutions of the Northwest, as well as taking the place of coal in the operation of the great fleets of ships which ply the Pacific. Due to the lower wage scale obtaining in British Columbia, and the fact that Canadian coal could be brought into the Northwest duty free, Northwestern coal-mine owners where rapidly losing much needed sleep worrying about where they would turn next to make both ends meet. Great activity in the lumber camps and lumber mills of this section in 1917 resulted in the production of an enormous amount of slab wood, which sold by the cord far under the price for a ton of coal; and as practically every community in Oregon, Washington, Idaho and Montana has from one to several lumber mills, the fuel consumer turned to the cheaper commodity.

However, these conditions changed with great rapidity for the better. Early in 1917 the Government

contracted for practically every barrel of surplus oil from the California fields, and the factories, apartment houses and ships which had been converted from coal burners to oil reversed the procedure and once more became coal burners; and it is not likely they will ever go back to the oil-burning basis. Great increases in British Columbia industry shut off the competition from there somewhat, as well as from the lumber mills, which off and on were tied up by labor disputes. War industries and new manufacturing, and shipbuilding plants grew almost overnight, and the coal trade of the Northwest suddenly found that it could no longer meet the demand. Prices rose to greater heights than in many years and continued high until the office of the Federal Fuel Administration was established.

Unlike many Eastern cities, which witnessed the growth of purely war industries that will now be closed down because of the lack of demand for their products, the cities of the Northwest that added to their manufacturing strength during 1917 and 1918 will retain them; for practically all were established to supply the natural demand of growing communities, and they accepted war orders only as they overflowed from the Eastern centers.

Large Increased Population in Northwest

The population of such cities as Seattle, Portland, Tacoma, Spokane, Butte, Boise, Salem, Pocatello and others has increased phenomenally in the past year, which means that the household consumption of coal will be as great as it was last year. It is freely predicted by both shipping interests and coal operators that the increase in foreign trade passing through Puget Sound ports this year will grow so greatly that coal from Washington mines delivered to ships will approximate 50 per cent. more than in any previous year. Industry will take as much if not more coal than it did last year. Northwest coal operators are not expressing any fears over competition from British Columbia mines, for from all reports increased industry in the provinces is taking practically all surplus coal from the mines at home.

Industry throughout the west has increased as greatly as has the population, and coal production has advanced accordingly. While 1918 will probably prove the banner year for the tonnage of coal mined in the West, it will also prove the banner year for consumption of coal in this section. Figures furnished by the mine inspectors of the various Western states show that the Pacific Coast can be independent of the rest of the country as far as fuel is concerned, the estimated production of coal mines in the eleven Western states being 40,339,000 tons for last year, as compared to an estimated consumption of 26,017,348 tons. These figures compare with the 1917 figures as follows: Consumption in 1917, 23,256,707 tons; production, 37,896,380.

The Northwest had to draw largely upon Utah last year to fill the coal bins of the householder and the industrial plants. The figures given in the table accompanying this article show that the coal production in Washington, Oregon, Idaho and Montana was but 9,039,000 tons, while the consumption was 12,592,848 tons, a difference of over 3,500,000 tons. This means that the Northwest coal mines could have produced over three million more tons of coal and disposed of it in their own localities during the year. Had the mines of the State of Washington had the facilities to produce this extra amount of coal, which was shipped in from other communities, they could have secured this business; but operators are of the opinion that it will be a long time before the coal mines of the Northwest will produce sufficient coal to equal the demand.

No new development work to speak of was undertaken in the Northwestern states last year, primarily because of the shortage of labor, the high price of equipment and materials, and the operations of the War Industries Board, which controlled the opening of new mines. Operators in this section are of the opinion that during the next two years there will be greater development of coal mines in Washington, Oregon and Montana than ever before in the history of these states, due to the fact that there is such a great demand for fuel, and the

PRODUCTION AND CONSUMPTION OF COAL IN THE WEST

	1917		1918 Estimated

Totals	37,896,380	23,256,707	40,339,000	26,017,348

a No producing mines. *b* Figures include both domestic consumption and coal consumed by railroads operating through the state. *c* 356,000 tons imported from British Columbia and east. *d* Does not include railroad fuel. *e* 180,000 tons imported from British Columbia. * Denotes total production of states so designated as 5000 tons.

further reason that so little development has been undertaken in the past three years. Considerable activity is already indicated at Roundup and Bozeman, Mont.; in the Teton Valley, near Boise, Idaho, and at the coal fields near Chehalis, Cle Elum, Bellingham, Cokedale and Colville, Washington.

Coal operators generally throughout this section are emphatic in their declaration that there is no longer a necessity for the continued functioning of the Fuel Administration, though admitting that during the past year the operation of the Government body has resulted in the introduction of certain features and economies which have materially helped the coal trade. One of the likely developments in the Northwest where large coal mines are in close proximity to large cities, operators believe, will be the locating of steam power plants at the mouths of mines instead of in the cities as heretofore, doing away with the extra handling and hauling of fuel. Another economy which will be carried along after the war will be the elimination of so many retail dealers. The shortage of both labor and railroad cars has awakened the trade to the vital need of storage facilities in the cities. Some communities like Seattle, Tacoma, Portland, Boise, Butte and others where large tonnage was consumed had little or no facilities for the storing of coal last year, and the seaports were backward in bunker facilities for loading ships. Operators and dealers state that this condition will not exist again.

Coal operators likewise predict that the next few years will witness great strides in the burning of

powdered coal in industrial plants of the Northwest, which was the first section of the country to undertake this method of fuel use on a general scale. In the City of Seattle two large power plants, several office buildings, department houses and industrial plants are now burning powdered coal. These formerly used fuel oil. All reports are most favorable to this new method of power and heat generation, the users stating that the powdered fuel is not only cheaper but is more easily handled and gives greater heat per unit than either oil or other classes of coal. Powdered coal is now delivered to the boiler rooms that use it in air-tight auto tank cars, similar to the familiar oil truck. It is the increased development of this method of fuel consumption which will prove one of the big things next year in this section.

Coal operators are not anticipating any serious difficulties with labor. The manager of one of the largest employing mines in the State of Washington states that he does not believe wages will go any higher, and that there will be an abundance of help for Northwestern coal mines. Under the present scale of wages obtaining at the mines a coal miner can earn more than the shipyard worker, now that the Macy award has been decided. The latter is not earning by 20 per cent. what he was when the attractive wage drew hundreds of coal miners to the coast shipyards. The miners are returning in great numbers, and Martin Flyzik, president of the United Mine Workers of America, District No. 10, who early in the year estimated that fully 1500 miners had left Washington mines, states that he does not think more than 380 of these are still out of the mines.

Operators also predict that the mines of the Northwest will produce at least 15 per cent. more tonnage this year than last, and that it would not be surprising if the mines of Washington produced 25 per cent. greater tonnage. With those estimates in mind we may expect a production of coal in the four Northwestern states of at least 10,000,000 tons this year, which would compare with 9,039,000 tons for last year and 8,445,749 for 1917. The coal trade of the Northwest is likewise satisfied with the outlook, due to the fact that it does not anticipate competition with Eastern coal for a long time to come, as a result of the high freight rates obtaining. The new year is being faced with optimism.

Middle West Coal Trade in 1918

By H. A. REQUA
Chicago, Ill.

A REVIEW of the coal industry of the Middle West, during the year 1918, will of necessity deal in extremes. There has existed no normal condition which ordinarily marks the transition of one period to another period diametrically opposite it. The year just ended has been a hectic one for producer and distributor alike. It has been a year of a feast and a famine, with so short a time between the two that there was little if any time for readjustment.

A year ago saw low-grade screenings, loaded from some Indiana or Illinois stock piles, which have been exposed to the weather for years, received by retailer or manufacturer alike, with tears of gratitude. Last week saw these same parties refuse the best coal this territory has to offer, on the shallowest possible pretext. A year ago the mines in Illinois, Indiana and Western territory were unable to take care of the tremendous demands made upon them. Today it is fair to say that the mines in the producing districts just mentioned could run from one-third to one-half time, and still manage to keep the public supplied with plenty of coal. Last January there was, in the Middle West and all over the country, a tremendous shortage of coal-carrying equipment. This year the terminals of the great coal-carrying railroads are cluttered up with strings of empty coal cars, because there is no demand for them at the mines. Twelve months ago the office of the state fuel administration in Chicago was besieged with people begging for coal. A few days ago we read in the paper that the state fuel administration has had to threaten these same people with legal action to make them take in coal ordered during the summer for winter delivery. It has, in truth, been a year of contrasts.

No synopsis of the past year would be complete without mention of the United States Fuel Administration and its activities. During the early months of 1918, each state had its own fuel administrator, appointed by Dr. Garfield at Washington. It was the duty of these state administrators to see to it that their respective states were kept supplied with coal, and that all available coal was divided fairly. In these first days of the year, numbers of the ablest operators and distributors of coal in Illinois and Indiana, in fact the whole Middle West, voluntarily left their respective businesses, and with an unselfishness which was a credit to the nation and the coal industry, placed themselves at the disposal of their state fuel administrators. Their help was invaluable, as their knowledge and familiarity with the coal business was of the greatest assistance to the state fuel administrators, who were usually men without previous experience along these lines. It is not an exaggeration to say that the best brains of the coal industry in the West could be found any time at the offices of the state administrator, working from 8 to 15 hours a day. Although their own businesses needed them as never before, these men placed themselves unreservedly at the service of the administration, and to them belongs the credit of successfully bringing us through a crisis in face of almost insurmountable difficulties. So much for the early days of the administration.

A little later in the year, the various state administrations were well organized, and were coördinating with a high degree of efficiency with the district representatives, who had been appointed by the administration at Washington to look after the production end of the industry, thus allowing the state administrators to give

their attention exclusively to the distributing end of the industry. High praise is due to such men as Dr. Honnold and Raymond E. Durham, of Illinois; W. K. Prudden, of Michigan; Evans Woollen and C. G. Hall, of Indiana; C. E. Reed, of western Kentucky; and W. N. Fitzgerald, of Wisconsin; as well as others too numerous to mention. These men, by their energy, discretion and ability, soon put the coal industry in their territories on a basis that relieved the public from any further worry, so far as an immediate coal famine was concerned.

The rapid changes that have taken place have been vastly interesting to watch, and the eventual development of them will no doubt leave a permanent impression on the industry. For instance, high-grade eastern coals, not including anthracite, will never be as strong in the Chicago market as they were before the war. People have learned, through necessity, of the high quality product from our own coal fields; for example, the Fourth Vein district, around Clinton, Ind. and the producing fields of Franklin, Williamson and Saline Counties in Illinois. This is also true of numerous factories in Indiana and western Michigan, which will undoubtedly continue using coal from our own Mid-Western producing districts, rather than a more expensive product from Ohio or West Virginia.

The history of the coal year has automatically divided itself into three periods, starting with the first of January, 1918, and consisting of four months each. These three divisions may be termed the period of shortage, of plenty, and of overproduction.

The first four months of the year were a record of the struggle on the part of the coal producers to keep up with the tremendous demands made upon them. Difficulty after difficulty appeared and was finally overcome. The supply of coal cars at Mid-Western mines was at a low ebb during all the early months of the year, but this particular situation was most serious during the last half of January and the first weeks of April. Labor was scarce and hard to hold, and it was almost impossible to get the necessary machinery for mining coal, or replacing old and worn-out parts. During this time the public was demanding coal and more coal from the Fuel Administration.

Record-Breaking Tonnage in Summer

From May to August, inclusive, the tonnage of coal supplied by the mines of Illinois, Indiana and western Kentucky was stupendous. The Fuel Administration had, by this time, established its zone system, and this, to a great extent, steadied the industry and put it on a more efficient footing. The public, in the meantime, were buying coal as it never had been bought before, and they were urged on in this by propaganda from the Fuel Administration at Washington, ably seconded by our own state administrators. Soon the zone decreed for the Illinois, Indiana and western Kentucky producing districts had absorbed about as much steam coal as it could hold, although the demand for domestic fuels kept up without abating. In July it was deemed necessary to enlarge our zone, and as a result we were allowed to ship steam coal to points in Michigan, Indiana and Ohio heretofore closed to our products. The bogey of a coal famine was feared, and in order to stimulate further coal production, the Fuel Administration appointed district production managers, whose duties were to see to it that more coal was mined. These men went to work with a will, and the Fuel Administration at Washington was gratified to note the substantial increases in coal produced. All indications showed that the public were buying strong, and all business was booked strictly on a basis of Government price current at the time of shipment.

During the last period, from September to the end of December, the apex of production was reached, and it has brought to light the fact that the zone decreed for us was not extensive enough to absorb the coal we were producing. Early in September there was a decided weakening in the market. At first, as was logical, this affected only the poorer grades of coal, and the demand for our high-grade products continued nearly as strong as before. Gradually, however, the demand lessened, until toward the end of the year there was practically no market for any kind of coal. It is said that during the first two weeks of December one of the best mines in the whole territory, from the standpoint of both quality and preparation of its product, ran only two days. The market started early in October to become serious for the operator, and the gravity of the situation has been increasing from day to day ever since.

Prices Well Maintained at Government Maximums

There is one noticeable feature, and that is, taking all things into consideration, there has been surprisingly little price cutting. The operators feel, and rightly, that our zone is practically glutted with coal, and it won't help, either individually or collectively, to cut prices. There are only two cures for an overproduction, the first being new markets, which unfortunately are unavailable, and the second, underproduction. Underproduction seems the only logical solution of the present problem, as the coal we have produced in excess of normal needs must be consumed before any strengthening of the market can be looked for.

It is almost impossible to forecast what the coming year has in store for the coal industry in the Middle West. At best it is largely a matter of personal opinion. It is pretty generally thought, however, that conditions will eventually adjust themselves, and that the situation will be, in all probability, near to normal long before the end of 1919. The Mid-West coal fields serve one of the richest manufacturing districts in the world. Europe is without a supply of all kinds of finished manufactured articles. The United States must fill this need, and the Middle West may be relied upon to get her share of the business.

It is safe to say that we may look for a period of great industrial activity in the near future. Again, it must be borne in mind, that outside the United States, Canada and Australia, there is practically a universal coal shortage. This means that eventually our eastern coal fields will be called upon to export millions of tons of coal, with the result that our mid-western mines will have to take care of districts logically in our territory, but now served by eastern mines. With one or two prominent exceptions, the larger operators and distributors are inclined to be optimistic as to the future, and as for a present policy, they echo the sound advice of one of our Western bankers, which is, "Until our reconstruction program is well in hand, do nothing hastily."

National Coal Association Now Planning for Peace Activities

With twenty-eight of its thirty-seven members present, the board of directors of the National Coal Association, as a result of meetings held in Washington Jan. 8 and 9, has mapped out a program of peace activities which will be more extensive than the war work done by the association. The board approved of what is expected to be the most extended cost-accounting activities ever undertaken in the coal industry. Traffic matters were recognized as being of unusual importance at this time. Every effort is to be made to see that the interests of the coal industry are considered in each step of the present movement, which may result in fundamental changes in transportation policies.

Arrangements were perfected for close coöperation between the National Coal Association and local associations in the carrying out of the association's plans. The local associations are to be relied upon to furnish the Government with statistical data so as to make possible the availability of the complete information which has been gathered during the war. Through the coöperation of the local associations, the National Association will furnish a market information service which will be national in scope. The meeting also was the occasion for submitting a concrete plan for an export coal association under the Webb Act.

The market service, which was authorized by the board of directors, was explained as follows by J. D. A. Morrow, the secretary of the National Association, in recommending that the service be furnished:

One of the most important things we can do is to give the industry full and accurate market information. This would mean daily advices to the National Association at Washington and branch offices from each local association and a return summary sent back to the local associations. Many other industries are conducting open price reports of this general kind on a national scale, such as cement, brick and lumber manufacturers, steel-furniture makers, pressed-steel manufacturers and others. Coal operators could do likewise, should they consider such action advantageous.

In making this suggestion of trade bureaus, price reports on closed transactions, etc., with national bulletins, I would not, nor would you, of course, countenance any activity that would transgress the anti-trust laws. Everything of this nature must be, and would be conducted in accordance with the advice of competent counsel and in a manner to make it obviously proper and legal.

These local associations could not only collect information with respect to prices, but should also obtain information with regard to production and distribution of their output, car supply, transportation conditions, etc. Information of this kind, which would be of general interest, should also be reported to Washington and would be included in the market bulletins of the National Coal Association along with any data released by the Geological Survey or other Government agencies.

It may be found advisable also to obtain similar information from the chief consuming centers such as New York, Boston, Buffalo, Cleveland, Pittsburgh, St. Paul, Minneapolis, Chicago, Omaha and other cities, and that for the purpose of interchanging such information—it being understood throughout that the information would relate only to past transactions—branch offices to be established at such points as Columbus, Chicago, Kansas City, and at least two other cities, one in the south and the other in the east.

The export coal association necessarily must be an entirely separate organization from the National Coal Association. The purpose is to develop a market for American coal abroad to all operators producing coal of the proper quality. The recommendations in this connection were made by the Foreign Trade Committee, of which George H. Barker, of Columbus, is chairman. The committee recommends the incorporation of the American Coal Exporters, Inc., under the laws of Delaware or New York. It is suggested that the organization be formed without capital stock and that its members pool their export interests in a manner which the committee describes. The plan is to be considered by the operators interested at a meeting to be held in the near future. An extract from the suggested plan of the committee is as follows:

If no capital is required other than such amount as will finance the expense of handling at tide and the expense of keeping records of the association, it would seem that the corporation might be organized not for profit and without shares of capital stock of any kind, in which event the corporation would have members instead of stockholders and the membership would consist of such coal operators as desire to avail themselves of the privileges and undertake the duties of membership.

Privileges, Terms and Conditions of Membership

Any operator or any local association of operators formed for the purpose of becoming a member of the association and approved by the association producing coal of quality suitable and available for export through Atlantic coast ports shall be eligible to membership in the association.

Each member shall be entitled to one vote.

Each member shall furnish the association such reports as the association may require, giving information, among other things, as to the following items: (a) Total production for the period covered by the report. (b) Tonnage consigned to the association. (c) Car numbers, weights and all necessary information concerning shipments made. (d) List of any and all contracts made for export coal, together with copies thereof. (e) Such other statements as the association may require with reference to the export business of the members. (f) From time to time, as called for by the association, information concerning market, labor,

car supply and other transportation conditions and all other items that are liable to have influence upon the members' production during the succeeding two months.

Each member shall sell its coal at its own expense, subject to the approval of price and terms of sale by the association.

The association is to receive the coal of all its members at tidewater, transfer it to vessels, and keep accurate, detailed accounts of all its transactions. The handling charges accruing at tidewater will be paid by the association and prorated monthly at each port among members on the basis of tonnage moving through that port during the current month.

Each member of the association is to pay its own railroad transportation charges to tidewater and is to pay direct the ocean freight and subsequent charges where coal is sold c.i.f.

Each member of the association is to be responsible for coal shipped to the pool and for demurrage and any other charges accruing in connection with the members' own shipments.

C. E. Lesher, the geologist in charge of coal statistics for the U. S. Geological Survey, and who has been in charge of the statistical work done by the Fuel Administration, addressed the meeting of the local secretaries and outlined some of his plans for the collection of statistics which will be helpful to the coal industry. Mr. Lesher has just been made head of the coal section of the mineral-resources division of the U. S. Geological Survey, which is preparing to extend importantly its work in gathering statistics and information of value to the various mining industries.

George W. Reed, of the Peabody Coal Co., of Chicago, was made chairman of the Railroad Relations Committee of the National Coal Association, and Thomas T. Brewster, of Illinois, was appointed chairman of the Cost Accounting Committee.

Director General of Railroads Indorses Coal-Zoning Plan

Stress is placed on the coal-zone plan as one of the most important factors in enabling the railroads to meet the coal situation, in a report by the Director General of Railroads which was delivered to the White House Jan. 7 for transmittal to the President. The zones, he says, have compelled the greater use of western coal and have resulted in the conservation, for war purposes, of eastern coal as well as permitting the greater production of both by avoiding useless waste of transportation. Continuing, he says:

The experience of the railroads under private ownership, especially with a demand for coal far in excess of the tonnage produced, was that shippers reached out into markets far beyond the territory in which their particular coal had normally been sold in previous years. The result was a very considerable waste of transportation, in that a much greater car mileage, reasonably estimated as running into millions of car-miles, was necessary to supply the country with its normal coal requirements than would have been the case had shippers chosen to content themselves with normal markets.

To meet this situation the Railroad and Fuel administrations jointly established what has come to be known as the bituminous coal zone plan of distribution.

Under this plan the various bituminous coal mining districts east of the Rocky Mountains were separated and each assigned a definite territory wherein it could market its coal. It was further provided that coal from any district could be shipped to destinations beyond the zone allotted to that district only upon permit of the Fuel Administration, which was recognized by the Railroad Administration as constituting exemption from the railroad embargoes which were laid down to give force and effect to the zone plan. This permitted proper distribution beyond zone lines of certain special grades of coal, coal for by-products use being a specific example.

The coal-zoning plan, however, did not merely save car-miles, and thus permit the production and transportation of several millions more tons of coal than would otherwise have been possible; it furnished, in addition, the means of utilizing coal produced in the Plains States, which would not otherwise have been produced. This was made possible by prohibiting the shipment of certain eastern coal to territory in the West which the war program required to be kept in the East.

In analyzing the situation and in telling of the unprecedented quantities of coal handled Mr. McAdoo says:

The most serious situation presented itself in the case of bituminous coal. This condition was the result of three factors:

1. An actual shortage of cars at the mines on account of the number delayed under load in the congested area and the limitations upon transportation due to the extraordinarily blizzard weather;

2. The lack of a systematic distribution, such as the Fuel Administration was arranging to provide; and

3. The dislocation of the New England supply, which was the result of the withdrawal of coastwise steamships, and which presented, on Jan. 1, 1918, the most serious single situation.

The bituminous coal production for the preceding year had been the largest in the history of that industry, approximating 544,000,000 tons, an increase of about 12 per cent. over the preceding year. The severe weather conditions prevailing in January, 1918, resulted in a decreased production, almost entirely due to car supply, of 65,294 carloads. Immediate and drastic steps were taken to remedy this situation and, notwithstanding the fact that the weather continued to be unduly severe throughout February and part of March, the railroads got on their feet, and in February produced an increase of 24,366 cars of coal over the preceding February, and for the succeeding months increases over the respective corresponding months of the preceding year were as follows:

	Cars		Cars
March	38,202	July	150,288
April	64,824	August	130,686
May	87,036	September	128,942
June	92,734	October	89,882

or a net increase for the 10 months of 741,666 cars, or approximately 37,083,300 tons.

New England's necessities have been fully met and the largest tonnage of coal ever known—28,153,317 tons—has been moved to the Lake Erie ports and transported to the northwest, compared with 26,826,000 tons in 1917; 24,692,000 tons in 1916, and 21,507,000 tons in 1915.

For the Lake season of 1917, 479,058 cars of coal were dumped into vessels at the Lake Erie docks, with an average delay of 2.3 days per car, which was the result of the first year's effort at coöperation under a single nongovernmental control between the railroads, the coal producers, and the Lake carriers.

For the season just closed 542,380 cars of coal were dumped into vessels at Lake Erie docks, with an average delay per car of 1.45 days. This very satisfactory result was attained through the coöperation of the coal producers, ore receivers, and the Lake carriers, with the Railroad Administration through the formation of the Cleveland Ore & Coal Exchange.

With regard to the New England situation, the report says:

The budget for New England coal for the coal year beginning Apr. 1, 1918, after exhaustive conferences with

the Fuel Administration and its New England representatives, was decided upon as follows:

Bituminous:	Tons	Anthracite:	Tons
All rail	9,182,200	All rail	5,165,500
Rail and water	20,504,900	Rail and water	5,165,500
Total	29,687,100	Total	10,331,000

Up to Nov. 30 the following tonnage had been moved:

Bituminous:	Tons	Anthracite:	Tons
All rail	7,502,463	All rail	3,887,981
Rail and water	12,228,041	Rail and water	3,058,304
Total	19,730,504	Total	6,946,285

It will be noted that as to anthracite the performance has exceeded the eight months' program by 58,949 tons, while the bituminous has fallen behind 60,896 tons.

Referring to the reconsignment of coal at Chicago, Mr. McAdoo says:

In Chicago terminals, it has been the practice under private control to reconsign practically all coal after arrival. By coöperation with producers, 66 per cent. of the coal arriving at Chicago, in August, was consigned direct to consumer from the mines, and cross-hauling coal between terminal lines was greatly reduced through the same coöperation, whereby coal was used wherever possible upon the rails of the individual road over which it arrived.

With the railroad's fuel bill amounting to $473,000,000 annually and representing the largest single item of operating expense, other than labor, the report devotes considerable space to the fuel conservation division of the Fuel Administration. It says:

This section was created May 1, 1918, with Eugene McAuliffe as manager, and representatives who had had practical experience in the use of locomotive fuel, as well as in its production, were asssigned to each region.

There has been constant coöperation with the Fuel Administration, and a consistent effort has been made to improve the quality of coal purchased for locomotive use, as well as to instruct enginemen in proper and economical firing. The cost of fuel to the railroads, now aggregating about $473,000,000 annually, exclusive of road haul on users' rails, represents the largest single item of operating expense other than labor.

The response made to the work of this section on the part of both officers and men has been of the most extraordinary and gratifying character. Meetings have been held throughout the country, which were attended by railroad officials and men; coal-mine operators and representatives of the Fuel Administration lending their presence and support.

The marked improvement in the measure of supervision and supervising methods established and the specific attention given to the selection and inspection of coal at mines, as well as the economical use of same on locomotives and in stationary plants, has resulted in very material fuel savings on the several railroads, and the revised methods of distribution which have been worked out will result in economy in road hauls.

Every change worked out under the advice of the Fuel Conservation Section has received the fullest approval of the regional directors and the various operating heads, with the result that methods established will be permanently maintained.

While deprived of the stimulus of war necessity, work in the Fuel Conservation Section will move along continuously broadening lines, the recent extraordinary increase in fuel costs rapidly bringing this angle of railroad-operating expense into such marked prominence as to warrant continual refinement in purchasing, operating, and maintenance methods. The determination of the most economical grade of coal for use on heavier-type locomotives, the selection of the best method of obtaining the maximum return in fuel economy from use of the locomotive superheater, the possibilities of the locomotive feed-water heater, and the determination of methods that will reduce the stand-by fuel losses of large locomotives are problems worthy of the most serious consideration.

Fuel Administration—European Commission Reports on Foreign Coal Conditions

The coal situation in Europe is such as to retard reconstruction in Europe to a marked degree, to say nothing of the discomfort and unrest that are arising out of it. This conclusion is based on the observations of the Fuel Administration's commission, which just has returned from a first-hand investigation of the fuel situation in Europe.

No European country has enough coal, the commission states, but the situation in Italy and Switzerland has reached an alarming stage of acuteness.

"The war emphasized the importance of coal, not only as an essential commodity, but as a diplomatic weapon of no mean proportions" the report said. "The present prospect is that it will prove no less a factor to be dealt with in the reconstruction period that is to follow—at least so long as the present potential shortage continues.

"For example, coal bears a very close relation to social unrest. The populations of the European belligerents have, during the war, suffered privations in varying degrees through lack of fuel. Will they continue to endure similar privations in peace times without active protest. Again, should the shutting down of factories, either directly through lack of coal, or indirectly through lack of transportation on account of failure of coal, result in throwing thousands out of work, will not a fertile field be provided for Bolshevism? Italy and Switzerland are today confronted with this situation, and it is an active possibility elsewhere."

With regard to the French and English situations, the report says: "France's production has for some time been 20,000,000 tons per year short of her consumption, and she is today calling upon England for that amount. Belgium during normal times produces 3,000,000 tons a year less than she consumes, but at the moment has in prospect a sufficient supply on account of the prostration of her industries. England, which has always supplied the needs of Italy and France, has suffered a falling off in production from 287,000,000 tons in 1913 to less than 230,000,000 tons in 1918. Her coal for export fell from 77,000,000 tons in 1913 to 37,000,000 tons in 1917.

"It is of interest to note that while all other great belligerent countries suffered a severe falling off in their coal output during the war, the yearly production of the United States is now approximately 100,000,000 tons greater than in 1913."

Other portions of the report will be made available in the near future.

Imports of coal in Hongkong, China, are much below normal and will continue to be so as long as high mine costs and high freights result in extraordinary prices to consumers in that city and in Canton. There has been increased mining of local coal deposits in various districts of Kwangtung and Kwangsi, but the output has not yet reached Hongkong in a commercial way.

Anthracite coal miners to the number of 6000 have been designated for discharge from the army. This figure is given by General March as of Jan. 4.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The year past has ended without any of the general strikes which sometimes appeared likely to materialize. It would seem that the industry should jog along pleasantly from now on, for the worst rut has been passed and the road is smooth beyond. The rut referred to is the general union election on Dec. 10. The various aspirants for office just before the election have to manufacture sentiment. If the feeling is unfavorable to the corporations and the wage scale, there is sure to be some one to take advantage of it and develop it as "the tide that leads on to victory."

So in every section of the country at the union election there is a flood of oratory in which the coal companies are treated most contumeliously. Those wanting reëlection show how valiantly they have assailed "corporate greed" and those who are postulants for the first time declare that if elected they will rectify all injustices. Both parties have to show up the horrible characteristics of the evil they have fought or which they pray that they may be allowed to fight.

Election Over, Discontent No Longer Aroused

The turbulence of all that oratory is over. Possibly it was not so bad this year as in other years, but in any event we sail smoothly once more into a more pacific sea. However, while the direct reason for scolding the operator is gone, the soreness which that scolding has caused still exists, and of that the insurgency in the northern field of the anthracite region is a symptom.

All of this refers to the unionized regions. In the nonunion sections the election period is relatively a time of peace, for the leaders and the aspirants for leadership are at home seeking from their following a warranty for their activity. They are busy "fixing their fences" to use a political phrase. We may expect that along the Great Sandy and in the western Kentucky region there will be a recrudescence of effort as soon as the results of the election are known. The nonunion sections are getting so few that the forces of the union every day become more potent to subdue them. The fight is apt therefore to be quite strong and the strikes that occur are likely to be generously financed.

Several War-Time Leaders Succeed Themselves

The election returns are coming in. In a short while, the outcome can be given in detail. There is a danger in premature announcement. Frank E. Waite of DuBois, for instance, was confidently declared to be the president of the great central Pennsylvania district, but now the district tellers have completed their work it shows that John Brophy, the former president, a Nanty Glo man, has renewed his term of office. James Mark and Richard Gilbert succeed themselves as vice president and secretary-treasurer respectively.

In Ohio, Subdistrict No. 5, the district where the Pittsburgh or No. 8 coal is mined in that state, William Roy and Frank Ledvinka are elected president and secretary respectively. This fact has been duly announced from headquarters though at an earlier date the opponents of these two candidates vigorously denied it. In Mason County, West Virginia, an unimportant mining county with about six mines, the election was held Dec. 4 instead of Dec. 10 as ordered. An investigation is being set on foot, but it is likely that only irregularity and not any actual dishonesty will be found.

The Elkins section has been transferred from District No. 16 to District No. 17. The former district had its offices at Cumberland, Md. By the transfer 13 unions come under the jurisdiction of the Fairmont office.

The anthracite region is experiencing some small strikes. At the Marvine colliery of the Hudson Coal Co. in North Scranton about 900 men went on strike Dec. 28. Some of the contract miners complained that something akin to a reduction in wage had been imposed on them, but on Jan. 1 they had a conference with Edward McGlynn, the superintendent, and went back to work.

At the close of the expiring year a strike was called by the machinists in the electrical mining department of the Delaware, Lackawanna & Western R.R. Co., Coal Department. The machinists wanted the same pay that is paid machinists in the railroad department, but Vice President Inglis refused them this concession.

Same Job But A Different Mule

The soldiers and sailors have been promised their jobs back now that the war is over. What that means Albert Bryant has been trying to determine. Albert Bryant had been working for the Pittsburgh & Cleveland Coal Co. at the Gaylord mine, near Martins Ferry. He left to join the army and later came back for his old job and was duly restored to his former place. Then he found that another man was driving his mule and was going to be allowed to drive that mule indefinitely. He got into an argument which resulted on Saturday, Dec. 28, in a strike of all the men employed. The strike ended, however, on the Monday following.

Want Accident Compensation and Cost of Living Equalized

An operator in southern West Virginia is urging that larger compensation be given to miners and laborers out of the compensation fund. He says:

"I am heartily in favor of any change in the compensation laws that will give the laborer his proper proportion of the money now on deposit at Charleston. We operators are contributing millions of dollars to the compensation fund which is being rapidly piled up and is doing no one any particular good. People can no longer live on the $6 or $10 per week which is the maximum amount allowed.

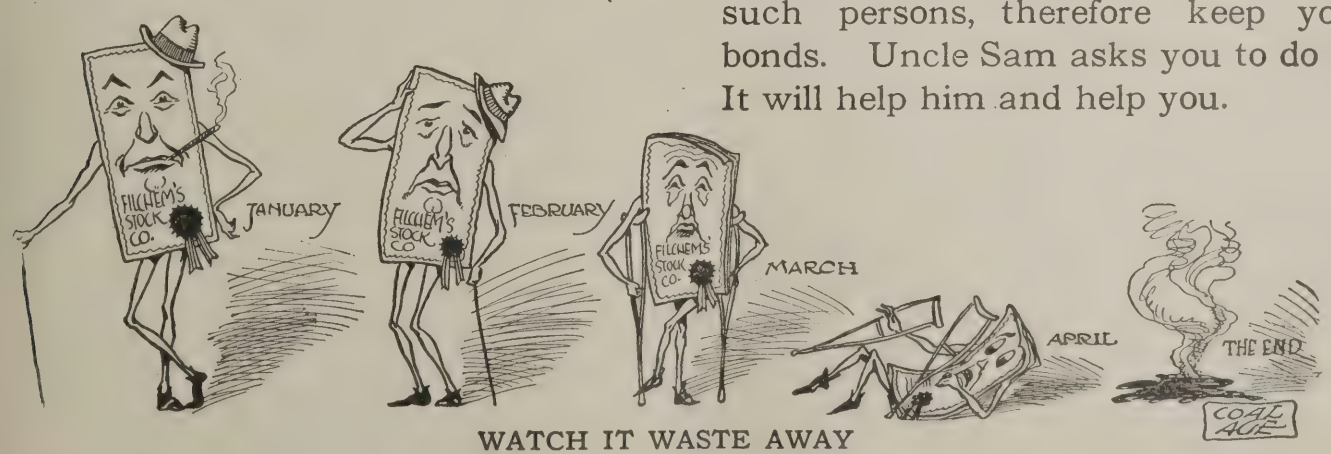
"When the law was made, board at the mines cost $15 per month. At this time the same accommodation costs from $30 to $37 per month, and this rate is likely to continue for some time to come. We should amend the compensation law so as to take away from the compensation commissioner his great power which now permits him to do what he pleases with the fund without question from anybody.

"We should increase the maximum rates of compensation. We should so amend the law that if a man is injured he can be sent to the nearest hospital, the state paying the proper charge. As the law now exists, if a man on the Winding Gulf is injured it takes two days to get him to a state hospital.

"If the man is sent to any other hospital close by, either the company or the man has to pay the bill. If a man has his teeth knocked out, his eyes injured or his face disfigured by powder the state hospital cannot handle the case and he has to be sent to a specialist to be treated, and neither the company nor the individual is required to pay for his treatment.

"As stated before, the coal companies are now contributing enormously to the compensation fund, because their payrolls are double what they used to be, while the rate is unchanged. Where they used to contribute $100 to the fund, now $200 must be contributed."

KEEP YOUR LIBERTY BONDS



SEVERAL dishonest persons know that you have bought Liberty Bonds, and they want to get them from you. They are plotting to exchange them for worthless mining or other stocks which they say will bring in big dividends. If you exchange your good bonds for the valueless stocks of these slick people, you will lose the bonds and never get any interest.

Even the best of stocks are none too good. On September 4, last year, fifty of the best stocks were selling at an average price of $90.45 a share. On December 20 of the same year the same stocks could be bought for an average of $57.43. These were all good securities. There are more that are selling at $90 today and will be entirely unsalable four months later.

Don't be a fool and waste the money you work so hard to earn. Play safe or you will come to grief. If the smooth rascals who are trying to sell you these bonds had such a good thing why didn't they go to some one who had money enough to send an expert to look the ground over? Some men will put their money out with somebody they *don't* know at Borrioboolagha who wouldn't think of trusting it with somebody they *do* know in a nearby village. Did you ever know anyone who cleaned up anything investing in one of these distant ventures? You know well that you can't recall any such persons, therefore keep your bonds. Uncle Sam asks you to do so. It will help him and help you.

Who Attacks Corporations, Attacks the State

THE Senate and the House of Representatives, together with the President, subject to the Constitution, pass laws enlarging or creating organizations such as the Army, Navy and Fuel Administration and giving them large administrative powers. Practically under the present law these organizations may not be criticized at all. That law has been administered wisely for the most part, and no attempt has been made to suppress constructive comment. Vicious, ill-intentioned, unmeasured, destructive criticism in the interest of our enemies has rightly been condemned and even prosecuted. The line is hard to draw between the two kinds of criticism. No two men would draw it alike, but the line is drawn somewhere, rightly or wrongly, by the secret service and the courts.

There are other organizations which, subject to the Constitution, owe their existence to the action of the Senate and House of Representatives, together with the President—such organized bodies are the corporations. There are also institutions legalized by the articles of Constitution such as private ownership of property. The institution just mentioned and the corporations, as also the Army, Navy and Fuel Administration and like creatures of our organic and statute law can all be legally swept away if we will. There is no radical change that we cannot make by appropriate legislative action.

However, just at present attacks on Government institutions are considered dangerous. It is felt that we attack not only the institutions themselves but the very life of the people for whose advantage and at whose behest the institutions were framed. When we attack them we attack the people—the state. Such attacks are contrary to public safety.

Some people are of the belief that the Army and the Navy and such institutions as the Fuel Administration, won the victory over our enemies. Back of the Army and Navy however stood industry without which the military forces of the nation would have been ineffective. The Fuel Administration merely marshaled the producing corporations. The Government departments all did a great work, but they could not have done it without the productive work of industry.

That productive work might conceivably have been done under direct Government management. For the nonce we are not discussing the question whether the Government would have done it better or worse than any other instrumentality, public, private or benevolent. The point is that to corporations and to private ownership we committed the work of providing the nation with the means of producing the wherewithal for war. They were the implements of industry to which the nation looked to back up the actual fighters. To attack those corporations and their officers unfairly and in a manner to inspire hatred was actually therefore to attack the instrumentalities by which the Government in its death struggle with Germany secured its needs.

Reference has been made to the war now past, but it must be remembered that times are still quite straitened. We still need to watch our steps, and it behooves us still not to assail unreasonably and unconstructively those institutions upon which the nation is relying to do its work. To attack the corporations is to attack the state. To expose the shortcomings of some of them in a reasonable manner as *Coal Age* has often attempted to do is not offensive but rather a duty. It tends to rebuild what is amiss, but we do as ill to criticise them destructively as to impute to the representatives of the Government offenses of which they are not guilty.

Much of the criticism of today is not based so much on the offenses of corporations as on the "greed of envy," as one of the greatest of our past Presidents termed it shortly before his death. That greed is at least as dangerous to the public as that "greed of arrogance" that a moiety of the corporations possess.

We all admit that those who attack the corporations unjustly offend against the corporations, but we sometimes fail to see that such injustice does not hurt the corporations much more than it does the people. Everyone should be interested in knowing the whole truth. A lie is an offense to the body politic. It is a false and mischievous diagnosis of the ills besetting the state. An evasion in telling the facts is also against the public policy. It may well hew at the base of the tree on which the public depends for its shelter.

The downfall of Russia did not so much result from the Government collapse as from the corporational disintegration that followed. Russia would have been a respected nation today if it had been contented merely to unship its Government. But the attack on the corporations has killed it almost irremediably. Not because corporations are essential to economic life. Some kind of existence is possible even under "politician ownership" if the politicians can be compelled to be reasonably responsive to their too often lightly made and lightly borne oaths.

But the politician ownership of Russia was not a responsible ownership, for the politicians of the Soviets who took charge were the least responsible of men and they put men in charge of industry purely for political and not for industrial reasons. Because a man had served a corporation and was not a politician was often considered to be a sufficient reason why he should be prevented from continuing the direction of a intricate and delicately adjusted plant, while a cunning politician, however ignorant of the industry—a mere broom wielder or porter—might hope for preferment to manager if only he vociferated with due diligence and fervor against the man who intelligently conducted that office.

It is because William G. McAdoo realized the excellence of corporational managements and largely retained the corporation men in control, it is because

the public was not so enraged at the railroads as to demand new officials in every department, that has given Government ownership of railroads its present success. However, credit must also be awarded to the spirit of coöperation to which the war gave birth and also to the habit of efficiency that one year of orderly politician ownership under the chiefs of the corporation ownership period (in this case we do not use the word "politician" disrespectfully) could not destroy. If we leave the railroads a few years under real politician control without the war stimulus, without the leadership of such corporation men as McAdoo, with all the disintegrating effects of politics, we shall have a horde of men inefficiently operating the railroads, neglecting their work for the politics of railroad operation, tangling themselves in red tape and treating the public with the arrogance which too often goes with civil-service jobs.

The trouble is that such careful readjustments as Mr. McAdoo has made do not in any degree appease most of those who so busily criticize private ownership. They frankly admit the work is only barely begun. The scrambling of the railroads, they would have, would be the end of railroad operation. Jobs would be given to those who want them, not to those who deserve them. Criticism such as is daily heard would raise wages and lower rates to a degree possible only in a world that neither knows the force of gravity and friction nor is bound by the law that "Two bodies cannot occupy the same space."

Removing Coal Mining from the List of Seasonal Occupations

IF ONLY we could stabilize the coal business so that a little decline in the immediate use of coal would not involve the closing of our plants, we should do a great deal to make conditions in the mines more satisfactory and equitable. If the miner is industrially undisciplined, it is because of the operation of the economic law which we may call the law of the "retention of the shiftless."

Any man who wants steady work will not stay at an excessively seasonal, unsteady job. He needs a daily round of toil to stimulate him, to meet his natural craving for activity. He resents the loss of pay which idleness causes. As a result, where work is unsteady the shiftless are retained and the energetic are lost to the industry. Association with shiftless men and conditions favoring the development of the shiftless spirit gradually create in the steady man that shiftlessness which enables the operation to hold the man to the job despite its many drawbacks.

Steady work makes men reliable workers and enables an industry to retain such men. But with coal (a relatively unstorable commodity that slacks on storage, catches fire and sometimes turns white from the presence of pyrite; that costs so much to store and so much more to load; that takes up so much valuable room near the market and often finds place for storage so rare near the mine) it is hard, though by no means impossible, to provide for storage in such measure as will make summer a time of preparation for winter demand.

The mines are in many ways the ideal places to store coal. A coal-using corporation must in most cases pile its fuel some distance from the point at which it is consumed. To transfer it when needed, it is necessary usually to employ a wagon or a wheelbarrow train, both of which means of transportation are expensive. At the mine the coal can often be dumped near the railroad track without trouble and can be loaded by a conveyor into cars on the track nearby.

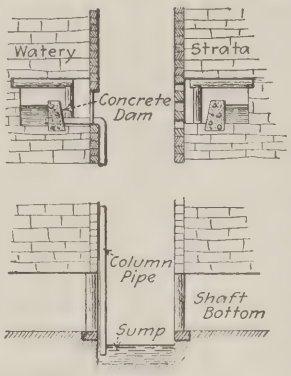
The cost of loading is much lower because the work is on a large scale, whereas in a big city the loading may have to be done by shovel because the work to be accomplished is so small that it does not pay to invest in a conveyor. Especially is storage expensive when a corporation has to stock coal on one lot in order to use it on another. If the place chosen for stocking is near a railroad, river or harbor dock, the double haul is saved; but the rental cost of storage is apt to be prohibitory. If it is in a vacant lot, the rental may be quite low, but the double haul and the loading and unloading will make the labor cost of storage unreasonably higher.

This consideration makes the mine seem the ideal place, but there are several disadvantages which militate against its choice as a storage ground. There may not be available ground near the mine; there is the risk that coal stocked at the mining plant may have to stay there because of such inadequacies of railroad and trucking transportations as arise from equipment shortage and strikes; there is the probability that in the event of a mine strike the mine workers will not load the coal, and there is the likelihood in case of a winter of light demand that the purchaser will not pay the storage charge.

He certainly will not pay it unless competition makes him, unless indeed he has been guaranteed that the coal will be stored to his order and not delivered to any other purchaser. Only by such a guarantee will he feel he is insured against the risks of a fuel famine. It might seem on first consideration that if the mine owner were to make a contract with this kind of guarantee he might find it profitable. A price might be made for coal to be delivered in December, but to be mined in the summer and specifically set aside for the use of the consumer so contracting.

The trouble arises that the operator having only a partial supply of cars would not want to surrender the use of them to the purchaser of his summer coal, thus closing down his mines in the winter. The railroad might be asked to concede extra cars for such stored coal, but its interest is all the other way. It desires that all the coal possible be hauled in the summer and a minimum in the winter. It would do nothing to aid summer storage at the mine, and it would be right, for its interest in the matter would be identical with that of the general public.

Clearly then seasonal price variation is the best cure for the seasonal demand. This rewards the summer buyers for the expenses of storage and its interest cost. The railroads and mine workers should assist in creating this variation in price by freight and wage-rate differentials. The operator has always made seasonal concessions and will undoubtedly continue to do so.



If there is to be any let up in the whole year it should be in the winter, when work on the surface is least endurable, when transportation is most difficult, when embargoes are most usual and when holidays are most frequent. Yet it is precisely when work is coldest and cruellest and in the day of festive celebration that we speed our operations to the limit.

DISCUSSION BY READERS

Freezing of Shaft in Winter

Letter No. 7—Kindly permit me to present what, to my mind, is the only efficient way to handle water in a wet shaft and prevent the freezing of the shaft in cold weather. I offer this in reply to the inquiry of a superintendent, which appeared in *Coal Age*, Nov. 28, p. 1004. My plan is to keep the water from the shaft curbing and there will be no difficulty on account of freezing in winter.

In the accompanying figure, I have illustrated the method of dealing with this trouble, which I believe is the best plan to adopt. It consists of making an opening in the shaft curbing, at a point just above the hardpan and at the bottom of the water-bearing strata. Excavate the strata, here, by driving an opening around the shaft, either next to the curbing, as I have shown in the figure, or back in the solid strata. If the opening is made close behind the shaft curbing it will be necessary to build a concrete dam encircling the shaft, so as to form a basin where the water will collect. This dam is sunk a short distance into the hardpan forming the floor of the opening, so as to make a watertight joint at the bottom of the dam.

DRAINING A WET SHAFT

As shown in the figure, the column pipe passes through the dam close to the floor, thus providing for the draining of what water collects behind the dam and conducting it to the sump at the bottom of the shaft.

In making the excavation around the shaft, it will be necessary to properly support the roof with timbers, either by hitching one end of the collar into the rib, as shown in the sketch, and supporting the other end on a good leg, or by other suitable timbering.

Rawdon, Que., Can. C. McMANIMAN.

Letter No. 8—In connection with the interesting discussion regarding the freezing of shafts in winter, permit me to instance two cases where I had to contend with the same trouble as that described by the Illinois superintendent, whose experience started this discussion. Although I fear that my experiences will simply be a verification of the editor's opinion, as expressed in the reply to the inquiry, I will give them for what they are worth.

The first case was that of a newly-opened, nongaseous mine, ventilated by a temporary, nonreversible fan of antiquated type. The fan was operated as a blower, and supplied about 20,000 cu.ft. of air, against a water gage of less than ½ in. The fan was set at the side of the air shaft with which it was connected by a concrete air drift 7 x 8 ft. in section.

As the water came into the shaft throughout almost the entire depth, it was not possible to collect it at any point before reaching the bottom. In cold weather, this water would freeze so that it was necessary to dig out the ice formed, with picks, every few days. To use the cage for this work was, of course, out of the question, and a swing scaffold had to be lowered into the shaft to support the men while at work.

To remedy the ice trouble, in our shaft, someone suggested the idea of turning the exhaust steam of the fan into the shaft, and this was done, with the result that the next morning the whole shaft was lined with a beautiful coat of frost about 2 in. thick, which showed the folly of that plan.

We next tried putting two radiators in the fan drift, between the fan and the shaft. These were each formed of eight rows of 2-in. pipe 40 ft. long, making 640 ft. of pipe in all. One radiator was placed on each side of the drift. Steam was supplied to the radiators at a pressure of 95-lb. gage. If the radiators had any effect to reduce the freezing of the shaft it was so slight that it could not be noticed. The result was that the pipe was soon after taken out and put to better use, as the men were still compelled to dig out the ice in the shaft, as before. When I left that mine it was the intention of the company to install a modern reversible fan.

Air Reversed in a Mine Generating Gas

The second case that I will mention was that of a mine ventilated by an up-to-date fan of the multiblade type, supplying 65,000 cu.ft. of air per minute against a 3.4-in. water gage. Normally, the fan exhausted the air from the mine, and the main shaft was the intake. In cold weather, not only did ice form in the shaft, but also on the track of the main partings and in the entry where water dripped from the roof, and cars were constantly derailed.

Since this was a mine generating both gas and dust, and the latter was highly inflammable, there was some hesitancy about tampering with the ventilation, even for the purpose of doing away with the ice nuisance. Owing to these conditions, the question of the probable effect of reversing the fan was much discussed, the general conclusion being that the change from exhausting to blowing would increase the mine pressure and hold back the gases; but any change from blowing to exhausting would have the opposite effect and cause a greater emission of gas.

It was decided, however, to adopt the experiment, and duplicate doors were then installed on all the main air-courses. These were hung to open in the opposite direction from the doors already in use, the idea being that one door could be set open and blocked, while the other was in use. Less important doors were supplied

with latches to keep them shut against the air, a nail being driven under the latch to hold it up when the latch was not needed.

These arrangements being completed, the fan was reversed on a Saturday night, after the shotfirers had come out of the mine. The examination of the mine the following morning by the fireboss showed the condition to be perfectly normal, there being no undue accumulation of gas in the workings.

The fan was only run as a blower for a short time. As soon as the ice in the shaft was thoroughly melted, the fan was again reversed and run as an exhaust, until the ice trouble again required its reversal. The exhaust system of ventilation was preferred, not only because of the danger of doors being left open in the mine, but for the reason that it was considered safer to haul the coal on the intake air, owing to the generation of gas and dust in this mine. I remember that it was necessary to reverse the fan and run it for a few days as a blower eight times during the winter.

Effect of Reversing the Fan on Generation of Gas Not Observable

Twice it happened that I was in the mine when the fan was reversed. With a safety lamp, I carefully watched the effect produced in a gassy working place, but could detect no change whatever in the quantity of gas escaping before and after the change was made, as indicated by the lamp. Naturally, my conclusion was that the difference in pressure caused by the reversing of the fan was so slight, as compared with the pressure of the occluded gases in the coal, that the effect of the change was practically *nil*.

In closing I will say that, after the doors were once installed on the main roads and the latches placed on the other doors, the reversing of the fan was no trouble. Firebosses and bratticemen were, of course, instructed to watch carefully for doors being left open at times when the fan was run as a blower and the air traveling in the opposite direction to normal.

Floresta, Colo. M. M. Watson.

Iron vs. Wood Mine Cars

Letter No. 7—In the recent discussion in *Coal Age*, concerning the best type of car to use, the question has been asked whether an iron or wood car has been found to be the most practicable for the average mine, with ordinary shop facilities.

The consensus of opinion, I believe, has been that an all wood car will give much better satisfaction than an all iron one. It is claimed that wood cars are more easily repaired when a wreck has occurred, and we all know that these are frequent enough to cause a great deal of trouble. It has also been argued that wood cars are easier on the track, because they are not as rigid as iron cars.

Comparatively little has been said, however, about the composite type of mine car, by which is meant the car with a wood bottom and steel sides. That, to my mind, is the most practical type of mine car that can be devised.

We know that one of the lightest and yet, at the same time, one of the sturdiest automobiles manufactured utilizes a wooden frame instead of an all steel framework, so as to take advantage of the resiliency of the wood. The service records show that such cars have not racked themselves to pieces as quickly as some others. But an automobile is not a mine car and it may be said that the above comparison does not apply here. Still, I would like to hear expressions of opinion from some of our readers who have used the composite type.

Owing to a policy of our management over which I have no control, I have never found it possible to try out any of the composite type of car, in our mines. But, since the question of new cars will very shortly come up and call for action, I would like to be fully posted, so that I can do my part to secure the best car that can be made. I want to ask, also, What type of wheels have given the longest life? By longest life, I mean the life of the tread, flange and hub.

W. Va. Progressive.

Blackdamp on Pitches

Letter No. 2—From my own experience with gas in pitching seams, it is quite clear to me that the gas found at the face of a pitch of 35 deg., in the Buck Mountain seam, as described by "Miner," *Coal Age*, Sept. 19, p. 568, is blackdamp. It would seem, however, that our friend has the idea that blackdamp, like carbon dioxide, is always heavier than air.

As has been explained in the reply to this inquiry, the common blackdamp of coal mines is made up of a mixture of nitrogen and carbon dioxide. In other words, it is mine air deficient in oxygen and containing more or less carbon dioxide, but the nitrogen is usually in excess, as has been shown by the analysis of different samples of blackdamp. The analyses of blackdamp that I have seen show the nitrogen varying from 85 to 88 per cent.; and, in one case, it reached 94.75 per cent. of the blackdamp mixture.

It is easy to see, from many analyses made of blackdamp taken from mine workings, that the mixture is much lighter than carbon dioxide. Also, as is sometimes the case, a small amount of methane present in the mixture will make the blackdamp even lighter than air, in which case it will naturally accumulate at the face of a pitch, or in rise workings.

Temperatures Taken With a Thermometer

After reading the interesting letter of Joseph R. Thomas, Oct. 17, p. 753, I was desirous of making the same experiment that he describes, in our own mine. Securing a thermometer, I proceeded up a gangway to a point where places were being driven on a pitch of 55 deg. One of these places was about 30 ft. above the first crosscut. There was not much air traveling at the face and blackdamp had accumulated there, so that an oil lamp was quickly extinguished and a carbide light became very weak.

After exposing the thermometer for ten or fifteen minutes on the gangway, where I found it registered 47 deg. F., I climbed to the face of the pitch just mentioned, but could remain there only five minutes, as I became very weak. In that time, however, the thermometer registered 57 deg. F. and was still rising when I started down to the gangway.

A little later, I erected a brattice that turned the air and conducted it to the face of this pitch. It was not

long before the gas was removed and the place clear; but a few days later I found the place again filled with blackdamp. This time I reversed the air, forcing it to the face of the pitch, and the gas was removed without any trouble, although the temperature of the return air at that time was 59 deg. F.

Strange as it may seem, on another gangway, where places were driven to the dip, I found the temperature on the gangway 40 deg. F., while at the face of the dip workings the thermometer registered 50 deg. F. Here, also, the mixture extinguished my oil lamp. The gas, however, was quickly removed by turning the fresh air into the place.

As before, we found, a few days later, the place was again filled with the same mixture. At that time, I found greater difficulty in attempting to remove the gas by turning the return current into the dip workings. I have since arranged to have the fresh air current sweep both of these places and there is now no trouble from gas in either of them. JOSEPH LAWRENCE.

Tomhicken, Penn.

Arrangement of Track Scales

Letter No. 1—In reading the article that appeared some time ago in *Coal Age*, the question arose in my mind as to what arrangement of mine-track scales would afford the greatest efficiency in the operation of the mine. Having due regard to expediting the work and, at the same time, securing an arrangement that would effect the greatest economy, the question presented is: Should the track scales at a coal mine be located under the tipple or elsewhere? In expressing my own opinion in this regard, I would like to hear from operators who are using track scales.

As we all know, in the majority of mines, there are usually three or four grades of coal to be loaded; namely, lump, nut, slack and, in some cases, egg and pea coal. When the scales are placed under the tipple it becomes necessary to install a scale on each track, in order to obtain the weight of each car of screenings, as well as that of the lump coal loaded.

DISADVANTAGE OF LARGE TRACK SCALES

Moreover, in order to comply with the requirements regarding the increasing capacity of the cars, these scales must be 72 or 74 ft. in length, which greatly increases the first cost of the installation over that of a regular four-section, 50-ft. scale. The increase in the cost of building the foundation large track scales is no small item.

Consider for a moment a mine that has four grades of coal dumped over the screens, and assume that four 72-ft. scales are installed under the tipple. To keep these scale platforms clean, so that correct weights of the coal can be obtained, will require the services of at least two men and, even then, in bad weather, two men will hardly be able to keep the scales clear. Allow me, here, to make a suggestion that appeals to me as being practical, hoping that it will be discussed and we may learn what others think of the scheme. It is as follows:

Install two 50-ft. scales, one at the head of the empty or storage tracks, where the weights of the empty cars acn be ascertained and recorded as they enter the yard; and the other at the point where the loaded tracks converge, where it will be possible to weigh each loaded car before it is shipped. With this arrangement it will take the weighmaster at the upper end but a few minutes in the morning to have enough cars dropped over the empty scale to run the mine at least half a day. When this is done he can perform the same service at the lower end of the yard, where each loaded car is weighed as it passes over the scale at that end.

SAVING OF TIME AND LABOR MEANS ECONOMY

To my mind, this plan would greatly increase the efficiency of the service. Time and labor would be saved in the weighing of the coal, which means economy. There would be less difficulty in keeping the scale platforms clear, which would mean greater accuracy in the weighing of shipments. Since cars are not continually standing on the scales, but merely pass over them, the life of the scales would be increased.

Those who have had experience with box-car loaders realize that it is especially difficult to maintain a scale in perfect order, under such conditions, owing to the operation of the loader keeping the platform of the scale in constant motion. The wear on the bearings of the scale is such as to greatly shorten the life of the bearings and impairs their accuracy. The bearings of a scale that is not subject to the same jar and motion will greatly outlast those that are subject to the severe service incident to loading the coal.

LITTLE DANGER OF OVERLOADING THE CARS

It may be argued that where the scale is not placed immediately below the tipple there will be danger of the cars being overloaded. To my mind, this is not a serious question, however, as it is practically impossible to overload an open car of 80,000 or 100,000-lb. capacity, and there is never any danger of overloading box cars of over 60,000-lb. capacity. There is frequently a margin of 10 per cent. over or under the marked capacity of cars, and, in this case, the man running the loader soon becomes expert enough that he does not often miss the limit.

In closing, allow me to state my conclusion that the extra cost of 72-ft. scales over those 50 ft. in length, together with the greater expense for foundations, both in respect to labor and material; and, in addition, the greater number of scales required where several grades of coal are to be loaded, make it certain that practical economy and more efficiency are secured when the track scales are not placed under the tipple. I hope to learn the opinions of others. E. C. DODGE.

Denver, Colo. Scale Inspector, American Fuel Co

Locating the Coal Beyond a Fault

Letter No. 7—In mining practice, faults are always annoying and costly to a greater or less degree, depending on the kind and size of the fault. It sometimes happens that, by following certain practical rules that are laid down, the lost seam can be located and development work continued without much delay. In other cases, the work of finding the lost seam is much more difficult and may prove a very expensive operation.

A common rule whose application, however, is restricted to normal or slip faults, is the following: If the fault is first met in the roof and recedes toward the floor, it is a downthrow; but if the fault is first met in the floor and recedes toward the roof it is an upthrow. This is only another way of putting Schmidt's rule, which is "Follow the obtuse angle in the faulted strata beyond the fault line."

It is quite evident that these rules will not apply to an overlap or overthrust fault. In such a fault, it would be necessary to reverse the rule and follow the *acute* angle, in the strata beyond the fault.

Applying the Rule Fails to Check Boreholes

Now, on examining the data and cross-sections shown in Fig. 1 on p. 797, where the correspondent states that the cross-sections shown are taken "looking at the right rib," it appears that this fault was first struck at the floor of the seam and receded toward the roof. Then, according to the rule just given, this should be an upthrow fault, running in a northeasterly and southwesterly direction. However, as proved by the finding of the coal by the boreholes, at a lower level than that in the mine, it is clear that the fault, in this case, is a downthrow.

Putting these facts together, I am of the opinion that this is an overlap or overthrust fault. This opinion is further strengthened by the statement that the appearance of the strata at the face of the main heading, in the fault, shows that the measures had been subjected to a tremendous pressure, as the rock there was much broken.

When a fault is encountered in a mine, it has been my custom to drive through the fault a short distance and examine closely the character of the strata beyond the slip. I would then compare this with the strata passed through in sinking the shaft. In the present case, however, the mine is a drift opening, which gives little opportunity to make such a comparison, although it may be possible to obtain some information from shaft mines in that vicinity if there are any.

Precautions Necessary When Drilling

Where no information is obtainable from this source, it is necessary to resort to drilling. Instead of sinking boreholes from the surface, however, I prefer to drill up or down, in the mine heading. Before doing this, the heading should be driven at least 50 ft. beyond the fault line, and enough top shot down to give sufficient headroom to insert the drills.

The fact that the coal found in the first drillhole was 3 ft. 9 in. thick while that in the second drillhole was 2 ft. 10 in. in thickness, in my opinion, means nothing in respect to determining whether the coal struck belonged to the X seam or the Y seam. It seldom happens that a seam of coal maintains its normal thickness when approaching a fault on either side. I have known cases where the coal beyond the fault would be thinner and other cases where it would be thicker than the seam worked, and this change in thickness will often be observed a distance of 50 ft. from the fault line. My belief is that the coal struck in the borehole belonged to the X seam and that, had the hole been sunk deeper, it would have found the Y seam just below.

West Frankfort, Ill. George Bowker.

Efficiency of Mine Officials

Letter No. 1—I have read a great deal in the columns of *Coal Age* in regard to the efficiency of mine foremen, but have seen little in reference to the efficiency of superintendents, which is a subject that I would like to see discussed by readers, or by some of the superintendents themselves.

My position brings me in contact with both efficient and nonefficient mine superintendents. Some of these have a reputation for efficiency, which to my mind they do not deserve. To judge rightly one must have first hand information. For instance, we see a superintendent on the street each day, with a white collar and seemingly having little care, and we are told that he is 100 per cent. efficient; he is producing coal several cents cheaper than another fellow, both in respect to labor and material.

There must be some reason for this; he must have an excellent organization, first class mine foremen, machinists and labor bosses, who thoroughly understand their duties and business. But you happen to know them personally and know they are not. I have, myself, visited some of these efficient plants. The mine usually has an excellent top, and little water to contend with, which accounts for the low cost of labor and material.

In such a case the superintendent knows little of what is going on at the plant, although the foremen keep reports in detail for his information, I find in many cases he sees these reports, but can he rely on them.

What a Close Examination Reveals

A close examination of many such plants, showing a low cost per ton of coal produced reveals the most wasteful methods in use. Such a condition may be attributed either to the inefficiency of the superintendent, or the failure of the company to provide the necessary labor and material.

Among the many inefficient things that one finds at these plants is the machine gang, where one man is working and two or more looking on. The boss carpenter is ready to sit down half an hour and tell you how things are going around the plant. Pumps need packing, which is generally due to the lack of packing rings or glands. Loss of coal results from water in the working places, the men being unable to work.

At many plants there is a lack of steam power, because of the formation of scale in the boilers, which makes the tubes to leak or the boiler to bag, causing a loss of coal of which no mention is made in the reports. One of the biggest losses underground is due to not having proper supervision of rib falls, and some means of removing posts and rails that have been partly covered up. The foreman generally has a good excuse ready when you see one of these places that should have the rails and posts removed. He will tell you that the rib boss is doing something else and will be here shortly; but he seldom gets there until it is too late.

I might mention several other ways in which waste occurs in mines, but the superintendents of the larger companies, these days, have many things to contend with that require, besides efficiency, some education, tact, a good judge of men, and broadminded, experience. However, I am not sure whether this is so necessary or not, with our uptodate methods in training men. It

has not been so long ago that a young fellow, in a barber shop, shaved and cut my hair. A few months later I found him superintendent at a good sized operation. I have been wondering ever since if this young fellow has some remarkable ability and how his superiors discovered his genius.

I believe that we have too many men in charge of our mines who lack the necessary experience and ability. After a year or more as superintendent they either lose their position or obtain another in time to prevent a complete tie up of the mine by reason of their poor management. Some of the larger companies, who keep an inspector for each department, manage to keep a superintendent who lacks knowledge if the foremen makes up for that deficiency.

Mine foremen, however, often prove failures; and it is at this stage that the superintendent requires tact to get rid of the foreman without incurring the ill will of the mine inspector. There are often young men working in mines who could fill these jobs, and what is lacking can usually be supplied, in some manner or way, so that the operator should not be compelled to go outside to get a man to manage his mine. Let us hear from many and try to learn where the fault lies, and where so much effort in man power and money is wasted, both in coal and in the material used in its production. There is no other business that will compare with coal mining, in respect to money invested and the amount of money lost. Yet we find the most inexperienced men in charge. Let us see if we cannot help in some way to correct the evil and learn just where the fault lies, with the operators or the men.

Uniontown, Penn. WM. GORMAN.

Waste of Coal

Letter No. 2—It was with deep interest that I read the letter of Russell Exline, *Coal Age*, Dec. 26, p. 1176. It was, indeed, a surprise to see the yearly wastage of coal published in such a mathematical summary. It is my belief that many who read the original report and never gave the waste of coal a second thought will be awakened to realize the true situation. While I do not fear a country wide famine of coal, it will be well to adopt the slogan, *We will never miss the coal, till the fire goes out and the bin is empty.*

Mr. Exline, in his letter, suggests a discussion of this question, from a practical standpoint; and let me say that I fully agree with him in the hope to see the ideas of other men on a subject of such vast importance.

It is a well known fact that many people do not consider it worthwhile to save anything that is plentiful. For just that reason, many miners' families waste as much coal in one year as a city family would use in the same time. This waste is carried on in two ways that are very noticeable. The first and most common waste occurs because many families never clean up the coal that the driver spilled while unloading their coal at the shed, but allow it to be washed away with the rain.

Again, by observing the ashpile of many of these families one will see that they are poor firemen, and that they fail to get the heat value out of the coal that they should. When their attention is called to the matter they say that it is the fault of the grate, which passes the coal unburned. It is just here that a good sound discussion of this topic will show the plain facts and teach such people the lesson of, "A dollar saved is a dollar earned." The truth is that, with a proper burning of their coal, they can save the cost of new grates many times over, and learn to be thrifty and better-living people.

There is, unquestionably, a large amount of coal wasted in mining the same. While it is an evident fact that all of the coal mined cannot be marketed, because there is bound to be some waste in its handling and shipment, yet I want to emphasize the fact that a good mine foreman, who insists on his miners cleaning their places well after every blast, will be saving more coal than a person would ever imagine.

Shiftless Habits in Mining Wastes Coal

The proof of this statement is shown at a mine where one compares the car accounts of chambers in the same vein and taken to be the same in all dimensions. Having watched with great eagerness the difference in the totals of two such chambers under my charge not long ago, I can truthfully say, that one miner when finishing his chamber had produced 575 cars of coal, while the man in the adjoining room, who was working under my guidance, for the proof of my idea, loaded 618 cars of coal, making a difference of 43 cars of coal in working a single chamber. I am proud to say, here, that the miner who loaded the most coal, in the case just mentioned, used three kegs of powder less than the other miner, who worked so carelessly, and that it took him one whole week longer to finish his chamber. He never cleaned his road, which was dirty and derailed his cars, compelling him to work harder than the miner who followed the instructions given him.

Later, when I made known to the careless miner the difference in the production of the two chambers, he asked for permission to work company work in cleaning his chamber. I granted him this, and when he recovered but 19 cars of coal he claimed that I had made a mistake in my accounting. It was then up to me to show him where the difference was. As he had not driven his chamber with even ribs and the full width, we both measured the width, in a few places, and he quickly saw where the difference of 43 cars in the two chambers existed. He admitted that he did not work to get the most coal per keg, which also gives the foreman a maximum production with a minimum cost. In closing, permit me to say that mine foremen who are working to get the coal out today, under the impression that they may not be on the job the next day, are neither working in their country's interest, nor that of the operator; but practicing a false economy. The sooner such a foreman abandons the idea of losing his job, the better record he will have for producing coal, when he finally resigns his position. The day is past when such a "flash in the pan" foreman can fool his company.

Plymouth, Penn. JOSEPH R. THOMAS.

[Referring to his letter on the "Freezing of Shafts in Winter," which appeared in *Coal Age*, Dec. 26, p. 1175, Jack L. Ball wishes to correct the statement in regard to the weight of the cages, in the next to the last paragraph on page 1175. He writes, "I unintentionally stated that the cages 'weighed between four and five tons.' These cages weigh three tons."]

INQUIRIES OF GENERAL INTEREST

Steam-Heating Plant

Kindly permit me to submit for consideration in the columns of *Coal Age* a question concerning a heating plant that we have installed at our mine. The plan, as proposed, is similar to that of a house-heating system, each radiator has a return-pipe connection leading to the boiler furnishing the supply of steam.

The plant is intended to heat three buildings and dry sand. The arrangement is such that the boiler is below the level of all the radiators and the return, at present, enters the bottom of the boiler. The lowest point in the return pipe is seven feet below the surface of the water in the boiler, and to come to the same level the water must back up 75 ft. in the return.

When starting this plant we filled the boiler with water, leaving the return valve open so as to permit the water to assume the same level in the return pipe as in the boiler. We then opened the valve in the steam pipe and started the fire. As the steam pressure rose, the water began to leave the boiler and, fearing trouble, we attempted to force more water into the boiler. By this time, however, the steam gage indicated a pressure of 40 lb. and the inspirator would not work against that pressure.

We were obliged to abandon the scheme and seek help in solving our difficulty. Allow me to ask whether the return pipe in such a heating system should enter the bottom or the top of the boiler. Please explain the reason the plant failed to work. MAC.

———, Mo.

In a steam-heating system such as described in this inquiry the return from the radiators should always enter the top of the boiler and never at the bottom. Apparently, this was the chief and probably the only cause of the failure of the plant to work.

The fact that the return pipe, in this case, entered the boiler at the bottom allowed the water, as stated, to back up in the return till it found its level 75 ft. away. This completely choked the pipe and prevented the circulation of the steam from the boilers through the radiators and back again to the boilers, as water of condensation. This condensation takes place more rapidly because the lack of circulation prevents quickly heating the pipes.

Now, regarding the water leaving the boiler as the fire was started and steam generated, the steam supply valve being opened, steam entered the pipe system and the cold radiators, where its condensation caused a partial vacuum on the return side. This explains the fact of the water leaving the boiler and being drawn into the radiators through the return connections.

The success of a steam-heating system depends absolutely on a free and unobstructed circulation of the steam from the boiler, through the steam pipe and the radiators, returning as water of condensation to the boiler. Not only should the return pipe enter the top of the boiler but it should then extend downward till the end of the pipe is well submerged in the water in the boiler, at or near the bottom. Without this submergence live steam would enter both the supply pipe and the return alike, which would effectively prevent circulation and block the system.

An Extraordinary Water Gage

Allow me to refer to an examination question answered in *Coal Age*, Oct. 24, p. 798, the next to the last question on that page. Following is the question:

What pressure and power would be required to produce and maintain an air volume of 150,000 cu.ft. per min., through an airway 8 x 10 ft. and 3000 ft. long? What would be the total power exerted by the fan engine if 70 per cent. of the power was expended on the air?

The calculations of the pressure and power required to produce this circulation appear to be all right, and yet the pressure shown (95 lb. per sq.ft.) is far too great for actual practice in coal mining. It represents a water gage of $95 \div 5.2 = 18\frac{1}{4}$ in. and I want to ask where the trouble lies, as something must be wrong. Still, I have checked over the figures and find no mistake.

Common practice, I have always understood, is to ventilate a coal mine, under a water gage of two or three inches at the most. Is the question a practical one; or is it intended to mislead a candidate and cause him to think his calculation is wrong? Such a water gage could not be measured with the ordinary mine gage, which seldom reads more than four or five inches. One would need a tube fashioned after the style of a standard mercurial barometer, about a yard long.

Springfield, Ill. CANDIDATE.

We are glad to have this inquirer draw attention to this question, which any practical man realizes does not represent actual ventilating practice in coal mining. To carry a velocity of 1875 ft. per min. a distance of 3000 ft., including the return, would not be considered by any operator of experience.

We do not wonder that our friend suggests the possibility of the question being intended to test a candidate's confidence in his calculations. There are good practical men who, on obtaining a result showing an 18-in. water gage, would conclude that their work was wrong and throw it aside, ashamed to submit it in answer to the question.

We believe this question is an unfortunate oversight of the examining board, who did not stop to consider its impracticability. No examining board charged with the duty of examining practical men, to ascertain their individual fitness for the positions they seek, would be justified in asking a question intended to mislead a candidate. It would be a deception for which the candidate is wholly unprepared, and as such is unfair to many whose chief asset is their practical knowledge.

EXAMINATION QUESTIONS

Miscellaneous Questions

Answered by Request

Ques.—To what extent is coal dust found in the mines of Illinois? State fully the cause of its existence and how you would protect life and property from the dangerous effects arising therefrom.

Ans.—The mines of Illinois are, as a rule, dry and dusty to such an extent that special precautions have to be taken, in the operation of the mine, to prevent disaster.

The cause of dust, in coal mines, is primarily due to the soft and friable nature of the coal. The trouble is greatly augmented by the practices followed in the mining of the coal, however. Machine mines are almost invariably dusty mines, because of the large quantity of machine cuttings, "bug dust." The excessive use of powder in blasting the coal; shooting off the solid; failure to properly mine a shot are all causes of the undue prevalence of dust in mines.

To properly safeguard a dusty mine everything should be done to reduce to a minimum the quantity of dust produced in mining, blasting and hauling the coal. Remove promptly all accumulations at the working face; enforce strict regulations regarding blasting; clean and sprinkle roadways and air-courses and use dustproof cars.

Ques.—Two airways, one circular and the other square, each have an area of 81 sq.ft. and a length of 2500 ft.; what is the difference in the rubbing surfaces of the two airways?

Ans.—Since the circumference of a circle is equal to 3.545 times the square root of its area, the perimeter of a circular airway whose area is 81 sq.ft., is $3.545 \sqrt{81} = 3.545 \times 9 = 31.9$ ft. For a length of 2500 ft., the rubbing surface of this airway is $2500 \times 31.9 = 79{,}750$ sq.ft.

Each side of a square airway having an area of 81 sq.ft. is 9 ft. in length. The perimeter of this airway is, therefore, $4 \times 9 = 36$ ft.; and the rubbing surface, for a length of 2500 ft., is $2500 \times 36 = 90{,}000$ sq.ft. The difference in the amount of rubbing surface of these two airways is $90{,}000 - 79{,}750 = 10{,}250$ sq.ft.

Ques.—What instruments are necessary for a mine foreman, in the performance of his duties in the mine?

Ans.—The mine foreman should have and use the following: An anemometer for measuring the velocity of the air in a mine; a watch for observing the time; a tape for measuring the size of the airway for calculating the quantity of air in circulation. He should have and use a water gage, for determining the unit of ventilating pressure or pressure per square foot producing the circulation in the mine or any split or section of the mine. He should have a barometer to observe changes in atmospheric pressure, and a hygrometer to determine the degree of humidity of the mine air. The foreman should have a good safety lamp for observing the gaseous condition of the mine. He should have a compass to determine the direction of rooms and headings and to give sights. In an inclined seam, he should have a slope level for determining the degree of inclination or pitch of the seam.

Ques.—Supposing there are two airways, one is 4 x 12 ft. and the other 8 x 8 ft. in section; how much more air will pass in the one than in the other, with the same pressure?

Ans.—Assuming these airways have the same length and the perimeter of each being the same, for the same unit pressure producing the circulation, the quantity of air will vary as the square root of the sectional area. In other words, the quantity ratio will equal the square root of the area ratio. Therefore, the ratio of the quantity of air circulated in the second airway to that in the first airway is $\sqrt{64} : \sqrt{48}$; or 8: 6.9, which shows that the 8 x 8-ft. airway will pass $8 \div 6.9 = 1.16$ times the quantity that the same pressure will pass in the first airway.

Ques.—The velocity of the air in an airway is 5 ft. per sec. and it is required to increase this to 8 ft. per sec., what increase in pressure will be required?

Ans.—For the same conditions in the airway, the pressure producing a given circulation varies as the square of the velocity. In other words, the pressure ratio is equal to the square of the velocity ratio. But, the velocity ratio, in this case, is $8/5 = 1.6$, and the square $1.6^2 = 2.56$. Therefore, in order to increase the velocity of air from 5 to 8 ft. per sec., the pressure must be increased 2.56 times the original pressure.

Ques.—How would you approach the burning section of a mine, in case the conditions necessitated the sealing off of the burning section? What steps would you take to insure the safety of the workers and the success of their work?

Ans.—Without a further knowledge of the situation in the mine, the location of the section that is burning and the headway gained by the fire, this question can only be answered in a general way. The safety of the men and their prompt withdrawal from the mine is the first consideration, while there must be no delay in taking steps to arrest the progress of the fire and extinguish the same, if that is possible. Assuming, however, as the question states, that it is necessary to seal off the burning section, experienced men must be selected for this work. Equipped with the necessary tools and material, they must proceed to approach the section from the intake side. Only safety lamps must be used, and no attempt to seal off the section must be made until all the men have been withdrawn from the mine except those to be employed in the work. Wherever it is practicable to do this, the building of the necessary stoppings should be started at the return end, so as to reduce the liability of an explosive mixture forming in the inclosed space. Much will depend, however, on the conditions surrounding each particular case.

COAL AND COKE NEWS

Harrisburg, Penn.

United Mine Workers of the Lehigh field are not in sympathy with the insurgent movement started by some of the men in the Lackawanna and Wyoming Valleys, according to reports received from that section. Leaders of the union state that reports claiming an attendance of 300 delegates at a recent convention were exaggerated, and that only 114 men were there, and these not fully accredited from their locals. Miners here feel that action of the insurgents would tend to split the organization.

With the settlement of their grievances, the 900 striking employees of the Marvine Colliery of the Hudson Coal Co., in North Scranton, who have been out since Jan. 3, returned to work on Jan. 7.

Report of the Anthracite Board of Conciliation for the coal year ended Mar. 31, 1918, just issued, makes a volume of 363 printed pages. It shows that during the period all manner of grievances as to working conditions, rate scales to apply, payment and work in dispute were formally brought to the attention of the board. There came before the board 175 formal grievances, 154 from employees or their representatives, and 21 from the operators. Of the 175 cases considered, 39 were voluntarily withdrawn by complainants, 42 adjusted amicably, 47 withdrawn without prejudice. There went to the umpire 57 cases. He decided 23 against the mine workers and 22 in their favor. There was no answer to the board for decision in one instance, and one case was pronounced retroactive. In addition 34 cases are held under advisement during the year.

Operators cannot evade the payment of specified wage rates by calling an occupation or a place by some other name, ruled Charles P. Neill, umpire of the Anthracite Conciliation Board, in a decision handed down on Jan. 9, sustaining the complaint of contract miners at the Halstead colliery of the Delaware, Lackawanna & Western, Coal Department, at Duryea. The ruling is retroactive and carries with it a large amount of back pay.

The miners claimed a higher rate for gangway work. The company, it is alleged, set up a highly restricted interpretation of what a gangway is and tried to create the issue that the passages where the complaints worked were airways.

The umpire said that he understands fully the difference between gangways and airways, and while he admits that the passages in the controversy were not so wide as the usual gangway, he asserts that the tunnel was used for the purpose and he refuses to read into the language of the anthracite wage agreement meanings that were clearly not in the minds of the parties who made and signed these contracts.

The Anthracite Board of Conciliation announced on Jan. 9 that it has denied the request of coal operators for the abrogation of the war-time rule that $150 be paid the families or heirs of miners killed or fatally injured at work and that, in consideration of the payment, the colliery shall not suspend the day of the funeral.

Protests have been filed with the Labor Department by International President Frank B. Hayes, of the United Mine Workers, against the importation of Mexicans into the mining regions. He cites action of certain operators in bringing Mexicans into the anthracite fields.

Uniontown, Penn.

Sales of coal lands in Green County aggregating $2,500,000 were approved this week by Referee in Bankruptcy J. G. Carroll upon petition of the trustees in bankruptcy of J. V. Thompson. Involved in the sale are what is known as the Rockwell and Dorsey deals. The sale price averaged $450 per acre.

Denial that J. V. Thompson dominates the liquidation of his vast estate is made in the answer filed by the Thompson creditors committee to the petition made here in equity asking for the dissolution of the committee. The answer sets forth that the estate is under the jurisdiction of the court and that it only can permit or prevent the trustees in bankruptcy in carrying out its provinces. The petition was made by the trustees in bankruptcy of Isaac W. Semans and executors of the estate of George L. Hibbs, heavy creditors of Mr. Thompson.

After floating several miles down the Monongahela River, the tipple of the Redstone mine, Pittsburgh Coal Co., lodged against the abutments of the Sunny Side tipple. The structure was virtually undamaged, but will likely be broken up and rebuilt at Redstone. The tipple was loosed by the recent high water on the river.

Morgantown, W. Va.

The United States railroad administration has removed the differential in freight rates on coal shipped on the Monongahela and the Baltimore & Ohio from Monongalia County, and henceforth the rate prevailing on the Baltimore & Ohio will be in effect. This differential amounted to 15c. a ton in favor of the shippers on the old road and in the Fairmont district. Coal from the Tait mines at Randall, for instance, could be transported across the river and shipped for 15c. a ton less than on the Monongahela, the road which should logically handle it. For some time the North American Coal Co. and other companies on the Monongahela have been fighting for the removal of this differential. The new rates apply to all that part of the region south of the West Virginia-Pennsylvania state line.

Ever since the Monongahela was constructed, shippers on the lines of the Baltimore & Ohio from Fairmont, Clarksburg, Philippi and intermediate points have enjoyed what is known as the West Virginia regional rate. This was 15c. a ton less than the rate for shippers on the Monongahela, and necessarily placed the Monongahela operators at a great disadvantage. According to the schedule of tariffs now issued and made effective, Monongahela shippers will get the West Virginia regional rate, 15c. a ton less than they are now paying. This applies to practically all points, east and west, though there are possibly a few exceptions of no great importance.

The rate to coal operators on the Morgantown & Wheeling is now the same as the rate to shippers on the Monongahela. This removes a charge of 40c. a ton to the Scott's Run operators, and with the removal of 15c. a ton on the Monongahela gives the Scott's Run region the benefit of a total of 55c. a ton.

Fairmont, W. Va.

Prepayment of freight will not be exacted from operators of the Fairmont region as originally determined upon by the Railroad administration, at least for the present, protest against such prepayment of freight having been registered by the Northern West Virginia Coal Operators' Association, with C. H. Markham, Philadelphia, regional director of the Allegheny region of the United States Railroad Administration.

F. J. Patton, secretary of the association sent the following telegram to Mr. Markham: "This association, representing production of twenty million tons annually, requests that the instructions providing for prepayment of freight on coal not be made effective Jan. 1, and further that such instructions not be made effective at a future date, until hearings are held and producers given an opportunity to be heard."

In commenting on the protest Mr. Patton said: "All operators in the Fairmont region who have coal to be shipped to tidewater points would be obliged to prepay the freight if the new order became effective. All cars are billed at Keyser and would have caused no end of inconvenience to the local operators because the freight payment would have to be made at Keyser."

Charleston, W. Va.

Production in the Pocahontas and Tug River districts reached its lowest point at the end of 1918, only 156,838 tons being produced. This is only about one-third of the capacity of the district. The tonnage lost reached a total of 211,152, the biggest factor in such a loss being labor shortage which cost 194,430 tons. From car shortage there was a loss of 6586 tons and from mine disability 5127 tons, while no market was responsible for a loss of 5000 tons. The market for Pocahontas coal is unusually quiet. There was a material reduction in the coke output, only 30,166 tons being produced.

With a supply of cars in excess of any seen during the whole of 1918, and with a ready market for its product, conditions in the Fairmont district, contrary to conditions existing elsewhere in the state, are very satisfactory, the only serious factor in holding back production being a shortage of electric power. As showing how liberal the car supply has been it is only necessary to point out that during the week ending Jan. 4 the supply was never under 2000 cars a day and ran as high as 3300 cars a day. It was impossible of course to load all the empties furnished.

With the removal of certain embargoes against tidewater shipments from the New River district and with the prospects of additional coal-carrying vessels being available, the outlook in the New River district was somewhat brighter although embargoes still in effect tended to cut down production. There was no trouble experienced with the car supply and there was no shortage of labor. Existing embargoes, as stated, were responsible for holding production down to 81,984 tons during the first week of the year. A slow market and a large number of men out also held down production.

Conditions existing throughout December in the Kanawha district remained unchanged during the first week of the year, even a cold spell, general throughout the country, failing to stimulate the demand to any great extent, reserve stocks, according to Kanawha operators, being sufficient to meet any immediate demands. With coal still debarred by zone restriction from many markets and with buying at low ebb, business in the Kanawha district is unusually quiet, so much so that production for the week ending Jan. 4 was cut to 84,247 tons, though allowance must be made for the fact that only 50% of the mines filed reports, all of which showed 2639 working hours with a total loss of 1637 working hours. Of that loss 849 hours were due to labor shortage; 78 hours were due to car shortage; 225 hours were due to mine disability and 340 hours to no market.

McAlester, Okla.

Coal mines and local shippers are overwhelmed with orders for coal from Oklahoma, Kansas, Colorado and Texas. Orders have more than doubled since the recent severely cold weather set in. Mines are working overtime, and where during the summer and fall months there was threatened abandonment of the mining camps due to departure of miners to seek other employment, there is now a wild scramble among the miners, each seeking to get all the work and put in all the overtime possible.

While many operators blame the people for not heeding the advice of the Fuel Administration and laying in a supply of winter fuel during the summer months, others declare it is due to the shortage of natural gas, which has been used extensively for heating. The heavy demands have so reduced the supply of natural gas that many families have abandoned it as fuel for heating and are depending on coal.

With the decline of the natural gas production, coal operators see a great future to the coal-mining industry. Vast undeveloped deposits of coal underlie much of the land of Pittsburg and adjoining counties, and capital is needed for their development. With the growing demand for coal and large profits from the money now invested, additional investment is sure to follow and new mines will be opened.

As indicating the extent of the coal mining operations in the immediate vicinity of McAlester, it is disclosed that the payroll of the coal mines amounts to $850,000 every fifteen days, or 1¾ million dollars a month.

PENNSYLVANIA

Anthracite

Jeddo—The G. B. Markle Coal Co., one of the largest independent concerns in the anthracite field, has put another gang of Mexican laborers at work at the mines. A month ago 100 Mexicans were also given employment by the Markle Company.

Oneida — Through effective preventive measures taken by the Lehigh Valley Coal Co., influenza outbreaks that menaced fuel production at a number of small mining towns around have been squelched. There are only a few cases in these towns at present, and danger of another epidemic has passed.

Beaver Brook—Owing to the high rate of wages paid drivers, runners and company hands about the mines, there is a scarcity of contract miners according to operators. The men prefer "company work," because they are assured of a regular income and are not exposed to the dangers encountered by the men who blast the coal.

Lansford—Six federal and state fuel administration investigators have arrived in the Lehigh region to investigate the cause of habitual absenteeism on the part of some of the miners and to suggest methods of correcting the trouble, which has hindered production to a considerable degree. They are scrutinizing the time sheets at the collieries, and it is understood that "pay-day drunks" will receive special attention.

Plains—M. J. Healey won a substantial verdict in his suit against C. C. Bowman, of Pittston, when the jury awarded him $13,019 on his claim of $14,000 on overpayments under a coal sales contract. In the trial of the case, which lasted for three weeks and was bitterly contested, Mr. Bowman presented as a set-off a counter demand of $32,000, alleged to be due him as commissions and other fees, but this claim was ignored.

Pottsville—The pay for the middle of January throughout the anthracite region will mark the delivery of paid-up Liberty Loan Bonds to the various workers who have completed their payments under the schedule arranged at the time the bonds were purchased. Some of the coal companies will have its paymasters hand the bonds to the workers when paying their wages. A congratulatory speech will accompany each bond.

Wilkes-Barre—The school for miners at the Y. M. C. A., which has been successful during the past ten years, postponed from Oct. 15 to Jan. 7, has opened. The school is for men working in and about the mines, who want to better understand the principles of their work and be prepared for advancement. It is a course covering three regular years' work with an extra year of preparatory work men for who have had the privilege of a common school education. The fact that a man has his fees returned to him upon graduation ought to encourage a large number of ambitious men to take this course.

Scranton—Since the Davis mine cave law went into effect, back in 1913, only three companies operating in the city have complied with its provisions relative to supplying the city with maps of the mine workings underneath the streets. This fact was brought out at council meeting on Jan. 7.

A steam main supplying the school administration building in the 400 block Washington Ave., has been broken, due to mining operations, it is thought. For several weeks heavy blasting has shaken the building, and it is believed that slight settlings have been the cause of the cracking, although a close inspection has failed to reveal any evidence of settlings in the building itself.

Bituminous

Pittsburgh—The Consumers' Fuel Co. is rebuilding its tipple at Downs Station, W. Va. Roberts & Schaefer Co. of Chicago, have been awarded a contract for the necessary changes.

Big Run—McClure Brothers have opened a new mine near here in a vein of coal which has never been worked to any great extent in this section. A switch from the Buffalo, Rochester & Pittsburgh R. R. has been installed and shipments begun.

Greensburg—The Pittsburgh Coal Co. has completed negotiations for the purchase of two tracts of coal properties, comprising 2200 acres of Pittsburgh seam coal, fronting on the Youghiogheny River, and about 1400 acres in the Rehobah Church section, both in Rostraver Township.

Homer City—The new mines of the manufacturers Coal Co., on Yellow Creek, near Meco, are fast rounding into form. The incline plane and tipple has been completed, and it is expected that coal shipments will be begun in January. The mine is located on the Snyder to Possum Glory branch of the Pennsylvania Railroad.

Evans City—Edward Empfield, who has been general manager and actively engaged in the supervision of the Big Creek Coal Mining Co. mines near here, has sold his interest in the company to Pittsburgh capitalists and retired from the mining business. John L. Lowther has been made superintendent of the Big Creek mines since Mr. Empfield retired.

Du Bois—Unless a way is found to put under control the blaze now raging in a large tract of coal on the Black Diamond Mining Co.'s operation; four miles beyond Luthersburg, thousands of tons of coal will be consumed. The fire, which has been burning for more than two months, started in an airshaft, and is believed to have been caused by boys. An attempt is now being made to install a stationary pump to work until the fire is put out.

Greensburg—The Pittsburgh Coal Co. has purchased two big blocks of the Pittsburgh seam of coal in Rostraver township, one of 2200 acres fronting on the Youghiogheny River, and the other of 1400 acres, in the Rehobah church section of the same township. The latter tract runs almost to the Monongahela River, at Webster. For the 2200-acre block the coal company paid Mrs. Elizabeth Moore, of this city, $4,000,000, and $1,000,000 was paid for the other tract. This land was purchased 25 years ago for an average price of $50 an acre.

Harmarville—The Inland Collieries Co., has begun experimenting with a cement gun in its mine near here, to ascertain whether a coating of gumite on the roof will prevent spalling and roof falls by keeping the air from acting on the roof. The workings are in what is known as the Double Freeport vein, with a slate roof, and troubles with roof falls are frequent in various sections of the mine. Cross I-beams, which at present are being used on nearly all headings, will be eliminated if the gumite accomplishes the purpose intended. Thomas G. Fear, Harmarville, Penn., is general superintendent.

Punxsutawney—The Onondaga Coal Mining Co., which is reopening the old Onondaga mines of the Buffalo & Susquehanna Coal and Coke Co. near here, have installed two large buckets in place of the cages. These buckets, with a capacity of fifty barrels each, are hoisted at the rate of one per minute. In addition to this method of dewatering the mine hydraulic pumps are being used, and the water is gradually going down. A contract has been awarded for a new steel tipple, including preparing machinery, rock disposal plant and power house equipment. The plant is expected to be in operation this spring.

WEST VIRGINIA

Williamson—Fire visited the plant of the Steele Coal Co. at Mossy Bottom on Jan. 3, destroying the store and office buildings. An overheated stove set fire to the building. The loss entailed amounted to about $20 000.

KENTUCKY

Willard—The Little Fork Coal Co., after running into a fault in its first location, has recently opened a new entrance and started shipping again. Robert Gunning is manager.

Ivel—The Regal Block Coal Co. is ready to ship coal from its new plant, which is equipped with machines for cutting from a 42-in. seam. Pocahontas field interests are behind this mine.

Willard—The Lick Creek Coal Co. has installed a compressor outfit and is ready to operate a coal-punching machine at its local mines. J. W. Kitchen, of Ashland, Ky., is general manager of the company.

Lexington—The Zella Mining Co., after being promoted by R. D. Clere, of Ashland, Ky., was recently sold, and the new owners are now in shape to start shipping from a new operation on Beaver, near Lachey, working a 5-ft. gas coal seam.

Sutton—General construction work is now in progress in connection with a number of improvements being made at this place by the Frank Coal Co., of which H. H. Frank is superintendent. This company has also built a large number of new houses.

Prestonburg—Arrangements are being made by the Colonial Coal and Coke Co., operating at Prestonburg, Ky., to enlarge the company's operations, new territory having been acquired near the present operation. It is proposed, however, to use the same tipple for both operations.

Frankfort—It is reported that the Long Fork Coal Co., one of the new operations on the Baltimore & Ohio R.R. extension, in Floyd County, Kentucky, along Beaver Creek, has recently changed hands, and is now under the active management of W. E. Jones. The plant is located at Drift, Ky.

ILLINOIS

Springfield—Mine A of the Citizens' Coal Mining Co. has resumed operation after a shutdown of two months. About 100 of the old employees returned to work; there are vacancies for 50 more, which will be held open a reasonable time. The mine has a capacity of 1000 tons a day.

Carbondale—George R. Sheldon, of New York, for eight years treasurer of the Republican National Committee, is in a serious condition as a result of injuries sustained while inspecting a mine at Dowell on Jan. 8. Mr. Sheldon, who is a director of the Union Colliery Co., at Dowell, was crushed between a coal car and the rib of the coal.

O'Fallon—Eight St. Clair County men passed a mine examination at Springfield this week. They were Sam Hoopway, of O'Fallon, and Arthur McGee, of Marissa, mine examiners; George Grainger, Belleville, mine manager; Marshall Orr, Belleville; J. E. Copeland, Marissa; Arnold Steinkamp, Mascoutah; Harry Luechtefeld, Lenzburg, and Edwell Eddings, hoisting engineers.

Springfield—The closing of mines in Sangamon County, as a result of overstocked coal conditions, has caused considerable hardship among the miners, many of whom have lost much time because of the influenza epidemic. Of the 29 mines in Sangamon County, only two were said to have worked every day in December. A number of the miners worked two and three days, with the result that there were seven thousand miners in Sangamon County out of work for all or part of the time.

Marion—The Wickham-Burton Coal Co., of Chicago, has purchased the White Ash mine here from the Johnston City Washed Coal Co. This is one of the oldest operating mines in Williamson County.

The new mine of the Orchard Coal Co. east of here, near Pittsburg, and one of the most up-to-date in southern Illinois, has recently hoisted its first coal. It is an entirely new field, heretofore considered impracticable for mine development.

Belleville.—The Missouri-Illinois Coal Co. has filed an injunction suit in the Circuit Court here against the White-Sergent Coal Co. to restrain it from suspending operation of the Wilderman mine, leased by the plaintiff company to the White-Sergent company. Under the lease, which runs for 21 years, it is alleged that the White-Sergent company bound itself to mine all the coal in the mine and not shut it down. But the mine is now idle, and it is alleged that the equipment in the mine is being ruined by the accumulating water. Under the lease the White-Sergent company pays the Missouri-Illinois company 2½c. per ton for all coal removed from the mine.

Carlinville—What indicates another large enterprise for Macoupin County is now under way. A drill for the testing of the coal under a tract of 12,000 acres in Hilyard, Polk and Brushy Mound townships in Macoupin County, and also lands in Madison County, have been placed in the field by the Sullivan Drilling Co. for A. W. Crawford. One drill is located on the Anderson land near Plainview and another has been received and will soon be located in another section. This is the initial work of developing this 12,000 acre coal field, and if the drilling tests show a good thick vein with a good rock roof, it is said that options will be closed for the land and the field purchased and developed by some large corporation. Mr. Crawford is the man who promoted the sale of 30,000 acres of coal rights to the Union Fuel Co. and also 30 000 acres to the Standard Oil Co. of Indiana, the latter company now developing its field. The Union Fuel Co. has not done any developing, but it is rumored on good authority that this field will be opened within the near future.

Foreign News

Berne, Switzerland—An arrangement has been perfected between France and Switzerland by which the latter is to be furnished with 60,000 tons of coal monthly from the newly occupied mines at Saarbrucken. Switzerland requires 200,000 tons of coal monthly, and as she is getting virtually none from Germany, is in dire straits for fuel.

Sydney, N. S.—The opening of a new mine on the Cumberland coal areas of the Dominion Coal Co. is announced by President Mark Workman, of the Dominion Steel Corporation. At the new mine, which will be known as the workman mine, coal has been reached a few feet below the surface. Other new sections of the company's extensive areas will be opened up as circumstances permit.

Personals

John Madill has resigned his position as superintendent of the Stanley Smokeless Coal Co. mines at Dias, near Indiana, Penn.

A. A. Straub, general manager of the Connellsville office of the Superba Coal and Coke Co. has been transferred to the Pittsburgh office.

George A. Cokely has resigned his position as superintendent of the Tide Nos. 1, 2 and 3 mines of the Tide Coal Mining Co. near Homer City, Pennsylvania.

Joseph W. Wear, Philadelphia, Penn., formerly general secretary to local Fuel Administrator Potter, has been appointed assistant fuel administrator for Pennsylvania.

William Reid has resigned as mine foreman for the Cowanshannock Coal and Coke Co., at Yatesboro, Penn., to become superintendent of the new mines of the Dor-Mar Coal Company at Savan, Pennsylvania.

John E. Evans, formerly assistant sales manager and general purchasing agent of the Bell & Zoller Coal Co., of Chicago, Ill., has been appointed general sales manager of the Mikesell Brothers Co., also of Chicago.

L. B. Lewis, better known as "Doc" Lewis, has resigned as superintendent of the Acme Coal Mining Co. at Rimersburg, Penn. He will devote his time to looking after his personal operations in Clarion County, Pennsylvania.

H. K. Schoch, chemist, late of the National Bureau of Standards, Washington, D. C., and **George R. Cowan,** briquetting engineer, late of Ellington Field, Texas, have resumed their positions with the General Briquetting Co., 25 Broad St., New York, N. Y.

S. T. McMillen, formerly superintendent of the Fulton Run shaft of the Jefferson and Clearfield Coal and Iron Co. at Ernest, Penn., has accepted a similar position with the Caldwell Smokeless Coal Co. at its several mines near Heshbon, Indiana County, Pennsylvania.

C. B. Rowe has been appointed manager of the Superior Fuel Co., near Russelton, Allegheny County, Pennsylvania, effective Jan. 1, 1919, to succeed **Cavel Robinson,** whose resignation was recently announced. Mr. Rowe was formerly with the Consolidation Coal Co. in West Virginia.

John Stone, mine foreman of Coal Run No. 1 mine of the Coal Run Mining Co. at McIntyre, Penn., has been promoted to superintendent of the Tide Coal Mining Co. mines at Tidedale, Penn. Mr. Stone was formerly mine foreman for the Penn-Mary Coal Mining Co. at Heilwood, Pennsylvania.

Lieutenant George Hodges, former superintendent of the H. C. Frick Coke Co. at Collier, Penn., has received an honorable discharge from the service and has been named superintendent of the Frick mine at Continental No. 1. **R. H. Barry,** superintendent of that mine, has been transferred to Colonial.

William E. Lohm has resigned as general superintendent of the Ellsworth Collieries Co. The duties of the office are now and will continue to be filled by W. A. Luce, general manager, who has transferred his headquarters from Pittsburgh, Penn., to Ellsworth, to be more convenient to the operations.

E. S. Harman, Pittsburgh, Penn., assistant to Richard W. Gardiner, local fuel administrator, production manager of bituminous coal in the Pittsburgh district, and commissioner of the Pittsburgh Coal Producers' Association, has resigned to become sales agent for the Carnegie Coal Co., with headquarters in the Oliver Building.

F. D. Baker, late chief engineer for the Colorado department of the American Smelting and Refining Co., and from its inception in 1906 engineer of construction for the Carbon Coal and Coke Co., at Cokedale, Colo., retired Jan. 1, 1919, after twenty years' service. Associated with his sons, Mr. Baker will do a limited consultation work in Denver.

Col. C. A. Burrell, who before the war was chief chemist of the Bureau of Mines, and who, since this country entered the war, has been engaged in the important war work of developing the various noxious gases used by the allies, and who was recently discharged from the army, has allied himself with the Mine Safety Appliance Company, of Pittsburgh, Penn.

C. J. Brown, who has been connected with the sales divisions of the R. D. Nuttall Co. for the past three years, has become associated with Frank M. Erb, representing in the Pittsburgh district the Silver Manufacturing Co., National Forge and Tool Co., Horsberg Forge Co., and Meadville Malleable Iron Co. Mr. Brown will be located at 902 Second National Bank Building.

George H. Cushing has resigned as editor of our contemporary, *The Black Diamond,* to assume the position of Managing Director of the American Wholesale Coal Association, with headquarters at Washington, D. C. We believe that the American Wholesale Coal Association are to be congratulated on the choice of their Managing Director, as Mr. Cushing has long been identified with the coal industry. In his official capacity as editor of *The Black Diamond,* he has come in contact with both the producer and jobber of coal, and in our opinion is singularly qualified to fill with satisfaction the new position he has accepted.

Obituary

Howard G. Dewey, president of the New York State Coal Dealers' Association, died on Jan. 6, at his office in Gloversville, N. Y.

Benjamin R. Whitcomb, aged 57, owner of the mine of the Vermilion County Coal Co., died of Bright's disease Dec. 31. Mr. Whitcomb owned much other valuable real estate in and about Clinton. A widow, four sons and a daughter, survive.

T. H. Wilding, superintendent of the Wickham and Mabscott mines of the New River Co., died on Thursday, Dec. 26, of pneumonia which followed a severe case of influenza. He was ill less than ten days. A wife and twelve children survive him. Mr. Wilding was 46 years old. He had been associated with the New River Co. for eight years.

John E. Williams, Federal Fuel Administrator for the State of Illinois from the inception of Federal control to July, 1918, died Jan. 2 at his home in Streator, Ill. Mr. Williams, who was 65 years of age, was born in Wales, his parents emigrating to America while he was yet a boy. His life, which started with 15 years' work in the coal pits of Illinois, was concluded with his occupying a high place as labor arbitrator and in other public service.

Industrial News

Charleston, W. Va.—The Imperial Coal Sales Co., of this city, announces the reopening of its Western office, in the Union Central Building, Cincinnati, Ohio, effective Jan. 1, 1919. G. M. Kearns is Western sales manager.

Washington, D. C.—Removal of all restrictions as to shipments of anthracite coal of "egg" and "pea" sizes is announced by the Fuel Administration. This action was made possible, it was explained, by an increased supply and accumulation of these sizes.

Louisville, Ky.—Closing of all distilleries and breweries is being felt at the present time, as these concerns were good consumers. From present indications there is little chance of getting this business back again, as the prohibition movement appears to have settled the fate of the industry.

Washington, D. C.—All orders and regulations as to fuel conservation, except one relating to natural gas, were withdrawn on Jan. 10 by the Fuel Administration. Regulations as to zones and prices and some others remain in effect, but in accordance with the announced policy of the administration the question of fuel saving is now once more a matter for individual determination.

Louisville, Ky.—The R. E. Wathen Co., large consumers of coal when operating the R. E. Wathen Distilling plant, will again be in the market for coal, as the concern has turned its attention to corn milling, and erected a new corn mill adjoining the distillery on the Illinois Central tracks, south of Louisville. Power will be furnished from the power plant of the distillery.

Lexington, Ky.—The Colonial Coal and Coke Co. has arranged to spend $50,000 on improvements on the Chesapeake & Ohio, facing the Big Sandy River, near Prestonburg, Ky., where it is developing 1000 acres of high-grade domestic splint coal. An aërial tramway is planned for this mine. The mine now operated is one of the oldest in the district, but is slowing down in production.

Charleston, W. Va.—An effort is being made to have a miners' hospital established at a point convenient to the Coal River mining section, operators in that field being behind the effort to have this hospital established. Operators in the Guyan field are also behind a move to have a state miners' hospital established at Logan by the Legislature. It is claimed that none of the present miners' hospitals are accessible to either of these fields.

Hazard, Ky.—The annual dinner meeting of the Hazard Coal Operators' Exchange has been postponed until Jan. 21. It was found that a great many of the operators belonging to this organization would be unable to be present on the date first set for their meeting, as it was necessary for them to be in Washington on business connected with the National Coal Oeprators' Association. R. A. Hord, the Secretary of the Exchange, is expecting 100 per cent. attendance on Jan. 21.

Harrisburgh, Penn.—The Public Service Commission has recently handed down an interesting decision in a case brought by McPhilomy & McPhilomy, trading as the Franklin Coal Mining Co., Brisbin, Clearfield County, against the Pennsylvania Railroad Co. for refusal of permission to load coal into cars from wagons. The commission holds that the action of the railway company was "unjust, unreasonable and discriminatory," and has ordered the payment of the sum of $500 for damages.

New York, N. Y.—The Wilkes-Barre Coal Co. has contributed $50 to the New York County chapter of the American Red Cross in compliance with the request of Delos W. Cooke, Federal fuel administrator for the State of New York, dated Dec. 23, 1918. This penalty was exacted for delivering coal without a permit to the customer of another dealer, such delivery being a violation of the rules of the United States Fuel Administration. The Wilkes-Barre Coal Co. waived its right to have this case reviewed at Washington.

Buffalo, N. Y.—The Buffalo Wholesale Coal Association was organized on Jan. 8 with W. D. Ward, president; J. Bert Ross, vice president; F. J. Durdan, secretary and treasurer, and the officers and C. L. Couch and E. C. Roberts, directors. A constitution and by-laws were adopted. Meetings are to be held every second Wednesday. The association is the resultant of the Bituminous Coal Committee, which was maintained as a sort of semi-organization for some time, with E. C. Roberts as chairman. He declined to become the president.

Oklahoma City, Okla.—Oil and gas wells now being drilled in Okmulgee County, Oklahoma, reveal extensive coal beds underlying almost the entire county. At least two veins of coal have been encountered in every hole drilled, and in many wells more and thicker veins are found. Coal has also been found under Tulsa, Creek, Wagoner and Muskogee counties, and plans are now being perfected for the organization of several mining companies to exploit these coal deposits in connection with the oil industry.

Cleveland, Ohio—An important meeting of Ohio operators was held at Cleveland recently when action was taken to oppose the methods of the purchasing department of the United States Railroad Administration in breaking the price of coal when buying for railroad fuel. A resolution was adopted by the representatives of about forty large operators providing for the naming of a committee of four operators to coöperate with a similar committee of miners in Ohio and also to coöperate with operators' and miners' committees in the other three central competitive states. These states are Illinois, Indiana and Western Pennsylvania.

Springfield, Ill.—One bill of interest to miners which will be introduced in the next session of the Illinois legislature will be the establishing of safer appliances in Illinois mines. The abolition of the carbon lamp may be asked, on account of its danger in igniting gaseous air. Electric lights on miners' caps may be required. It is said that the electric lamp has never been much favored by Illinois miners because of the expense in upkeep. Alterations will be asked in the child labor law, the workmen's compensation act, and changes in various wage scales for organized laboring bodies. The legislative committee of the Illinois State Federation of Labor and the United Mine Workers are busy preparing a number of other bills to be introduced.

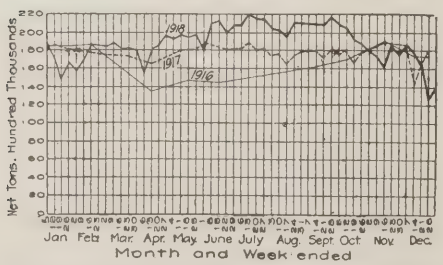
MARKET DEPARTMENT

Weekly Review

Coal Industry Marking Time—Indications Point to Early Resumption of Activity—Bituminous Demand Inactive—Anthracite Market Without Any Snap—Mild Weather Militates Against Urgent Demand for Coal.

UNTIL the nation's reconstruction program is well in hand the coal industry can expect no such period of prosperity as preceded the signing of the armistice. At the present moment the demands for bituminous steam coal are few. A number of large consumers who have cut into their reserve stocks are making inquiries, though of real active buying there is *nil.* The better grades of soft coals can naturally find a more ready market than coals of an inferior grade, of which there is a surplus. It is now a buyer's market instead of a seller's.

Indications would justify the conclusion, however, that these conditions will change for the better beginning late in February or early in March. By that time the country's readjustment plans will have been formulated and placed in motion, industry will have reorganized on a peace basis, the Government will have relinquished its control of coal, and export demand for coal and manufactured products will be unprecedented.



The output of soft coal, in the meantime, though nowhere near the maximum capacity of the mines, is still sufficient to take care of current needs. This does not apply to high-grade fuel, the demand for which exceeds the supply. During the week ended Jan. 4 the production of bituminous coal is estimated at 8,414,000 net tons, bringing the total production for the coal year to date to 456,243,000 net tons.

The anthracite market is without any snap, and dealers and consumers both are buying in a desultory fashion. This can be attributed chiefly to the remarkably mild weather for this season of the year. Restrictions have been removed by the Fuel Administration on egg coal, and this size can move untrammeled wherever a demand for it exists. Pea coal is as plentiful as ever, and there seems to be no shortage of either stove, egg or chestnut. Only a long-continued spell of severe wintry weather would serve to tighten the anthracite market.

During the week ended Jan. 4 the output of hard coal is estimated at 1,389,000 net tons, which brings the total production for the coal year to date to 75,219,000 net tons, approximately a million and a half net tons below the output of last year.

WEEKLY COAL PRODUCTION

Bituminous — Considerable improvement occurred during the week ended Jan. 4 in the production of bituminous coal, the output being estimated at an increase of 1,954,000 net tons, approximately 30 per cent. above the production during the week preceding. Estimates place production during the current week at 8,414,000 net tons, and while in excess of the production during the week ended Dec. 28, which amounted to 6,460,000 net tons, fell below production of the week ended Jan. 4, 1918, by 1,020,000 net tons, or 11 per cent. The daily average during the current week, based on five-day operation of the mines, is estimated at 1,402,000 net tons, one-half million net tons behind the daily average of the coal year to date and approximately 350,000 net tons behind the similar period ending Jan. 5, 1918. Total production this coal year to date, estimated at 456,243,000 net tons, exceeds that of last year by 34,248,000 net tons, or 8.1 per cent.

Anthracite—Anthracite production during the week of Jan. 4 improved to the extent of 100,000 net tons over the week preceding and is estimated at 1,389,000 net tons, as against 1,317,000 net tons during the corresponding week of 1918. The daily average during the current week, based on a five-day operation of the mines, is estimated at 278,000 net tons for the coal year to date and 320,000 net tons for a similar period of last year. The total production for the period Apr. 1, 1918, to Jan. 4, 1919, is estimated at 75,219,000 net tons and falls below production of the 1917-18 coal year through Jan. 4 by approximately a million and a half net tons.

Loading reports received from the carriers for the week ended Jan. 4 show an improvement in all fields compared with the week ended Dec. 28. The central and western Pennsylvania, Cumberland-Piedmont and Somerset and Fairmont fields, in which the demand for all coal mined is good, were also the only fields to show improvement in the number of cars loaded over the corresponding week of 1918. In the Illinois, Indiana and western Kentucky district the decrease in cars loaded, compared with the week ended Jan. 4, 1918, was approximately 10,000. The new calendar year figures begin with this issue.

New England Shipments—Shipments of bituminous coal to New England during the week ended Jan. 4 are estimated at 295,991 net tons and exceed the shipments during the week preceding by approximately 53,000 net tons. The receipts through the rail gateways, as well as shipments from each of the harbors, show considerable improvement.

Tidewater Shipments—Shipments by tidewater also increased considerably, estimates placing the tonnage for the week at 662,476 net tons, as compared with 583,072 net tons during the week ended Dec. 28. Considerable improvement occurred in the tonnage shipped from New York, Philadelphia and Baltimore, while shipments from Hampton Roads declined approximately 16,000 net tons, or 7 per cent.

Beehive Coke—The production of beehive coke in the United States for the week ended Jan. 4 is estimated at 496,000 net tons, as compared with 440,000 net tons during Christmas week. The current week's production, while an increase over the week preceding, fell 72,000 net tons or approximately 13 per cent. below production of the corresponding week of last year. In the Connellsville district of Pennsylvania operators produced 253,923 net tons of beehive coke during the week of Jan. 4, operating their plants at 69.8 per cent. of their full time as compared with 68.2 per cent. during the week ended Dec. 28.

Byproduct Coke—Necessary repairs to byproduct plants during the week of January caused production of byproduct coke to decrease approximately 14,700 net tons compared with the week ended Dec. 28. The current week's production, however, was far in excess of the production during the corresponding week in 1918, the increase amounting to approximately 162,000 net tons, or 42 per cent. The plants of the country were operated at 84.6 per cent. of their full time during the week ended Jan. 4 and out of total losses of 15.5 per cent., 9.1 per cent. was attributed to repairs to plants, 3.2 per cent. to lack of market and 2.5 per cent. to other causes. During the week of Jan. 5, 1918, the byproduct ovens of the country were operated at 80.4 per cent. of their full time and were limited in their operation at that time mainly by lack of byproduct coal, of which today there is practically no shortage. Considerable fluctuation in operating conditions occurred during the week in Alabama and Maryland.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running lower than for the corresponding week of 1918. Road sales for immediate delivery were in excess while for future delivery they were less compared with the same week of last year. More customers were in the house. Collections are good.

American Wool and Cotton Reporter—Justas soon as a basis of wool values can be established many believe it will be possible to sell cloth in at least moderate quantities. The minimum prices established in Great Britain are no fair indication of what values will be on a supply and demand basis. The stocks of wool are so large, and the prices have been so high, that there may be difficulty in disposing of the wool. In the cotton market there has been a greater amount of strength insofar as the details of supply and demand are concerned. There is no justification at all for higher prices for raw material. The exports are at least 250,000 bales less than they were at the corresponding period one year ago, and a more or less similar condition is noted for the stocks in warehouses.

The Iron Age—The pig iron production of 1918 was 38,506,249 tons. The December output was 3,433,617 tons, or 110,762 tons daily, and thus at an annual rate of 40,428,000 tons, but there were five months of last year in which a higher rate was maintained. The momentum of war effort is responsible in part, for December, 1918, exceeded the existing December record, that of 1915, by 7429 tons a day. The severe winter of 1917-1918 cut down the year's total. The November daily average make was 111,802 tons. The pig iron output of 1917 was 38,185,981 tons and of 1916, 39,039,356 tons. The rate of production on Jan. 1, however, was 109,675 tons per day, against 111,330 tons on Dec. 1. In the month 11 furnaces came in, but 21 went out and the number in blast on Jan. 1 was 350, or ten less than on Dec. 1.

Dry Goods Economist—The difficulty experienced by the Government in selling wool at the price it desires to realize, together with the removal of all restrictions on the importation of wool, points strongly to lower figures for this important raw material. Raw cotton has shown considerable fluctuation, but within a narrow range. Within a brief period the future course of the market will depend largely on acreage reports and new crop prospects, as well as on the development of the export situation. The latter has so far proved disappointing to those who figured on higher prices.

Bradstreet's—Trade at wholesale and with jobbers ranges fro monly fair to distinctly quiet, most animation being visible in the west and south, and most marked hesitation being noted at the large eastern centers close to large primary production. Industry is even quieter than in preceding weeks, with a greater percentage of capacity idle awaiting the readjusting process, which moves but slowly. Where readjustments have been completed as in a few lines, activity is being resumed guardedly. Of the three great departments of business activity, retail trade shows relatively most animation, due to clearance sales, which are extensively advertised, though decidedly colder weather overspreading the country has given a long-needed stimulus to final distribution of winter-wear goods.

Atlantic Seaboard

BOSTON

No inquiry. Railroads cutting fuel receipts. Problem to place few remaining steamers. Smokeless mines embargoed. Conferences between representatives of different Hampton Roads interests. All-rail movement slopes off again. Several shippers content to wait developments. Surplus of better grades at the New York piers. Anthracite receipts improve, although cold snap and tie-up in New York cause uneasiness. Restrictions off on broken and pea as well as egg. Local regulations off in Boston except as to price.

Bituminous—A thorough first-of-the-year canvass of the market discloses no buying interest whatever. A few scattering sales are made of high grade coal, but these are confined to retail dealers who now and then find outlet for a few cars. Coal at destination, however, particularly in cases where originally confined to some industrial, is next to impossible to dispose of. There have been a good many instances where coal requisitions filed through Government channels last summer have been taken out of pigeon holes by sundry operators and shipped regardless. There is practically no way of checking this until cars reach the consignees, and what remains of the New England Fuel Administration is kept busy with such cases. In Connecticut so little market is apparent that cars have been allowed to remain on sidings for weeks at a time and then turned over to the railroad for disposition. A more hopeless looking market at this writing would be hard to find.

The railroads that are usually the mainstay when such situations develop not only ceased buying but are declining to receive fuel coal on contracts. General traffic is so very light and the winter relatively mild that several thousand tons less every day are being used than a year ago, and it is only natural that with all the money invested in high-priced water coal during the season that the managements should now cut off shipments by water before those all-rail. This has been done quite generally the past fortnight. Shippers who have made continuous deliveries by steamer over long terms of years are now withholding deliveries. The result is that little coal is loading for New England at either Baltimore or Hampton Roads. Receipts of provincial coal from Cape Breton have also practically ceased.

More and more steamers are being tied up from week to week. Boats that were assigned on contract business in place of modern colliers owned here that were taken several months ago for overseas transport are many of them on the shippers' hands, and strenuous efforts are made to place them with the agencies who still have orders in hand. It should be noted that most of these ships are not on the regular Shipping Board terms, calling for $3.25, Hampton Roads to Boston, but that private arrangements were entered into based upon the cost of service by the boats that were commandeered. The Shipping Board has been looked to for some statement of policy, but the impression here is that nothing can be definitely decided until some understanding can be reached with the owners of foreign tonnage.

Because of the great surplus of coal at Hampton Roads over vessels entered to load two or three of the railroads have declared embargoes against tidewater movement and coal is not now reaching the piers in such heavy volume. At the present rate, however, it will take time to clear up the coal now waiting at the three piers.

The Boston trade is much interested and pleased to hear of the recent appointment of W. B. Calkins to be engineer-in-chief of the Tidewater Coal Exchange. Mr. Calkins has won a high place for himself for his thorough knowledge of coals and their origin, and his splendid work as chief inspector for the central Pennsylvania district since last spring does him great credit.

It is still extremely difficult to place coal arriving by water. All reports agree as to the extremely large reserve stocks everywhere in this territory, and where mill output has declined so the past 60 days the time is set farther and farther ahead when any active interest in the steam coal market can be anticipated. This state of things is decidedly awkward for the Pocahontas and New River agencies who want to be in favorable position with their operators this coming year. There are some hopes built upon the export and bunker trade, but on analysis that branch of the business is not so encouraging as might be supposed. At most points the differential is in favor of Welsh grades and the extent to which miners in Great Britain are returning to work it is fair to suppose that certain markets in South America will not be obliged to appeal to this country for their supplies. All of these questions are being discussed from time to time by the different Hampton Roads interests, and out of all the conferring it is hoped some sort of program will be laid down.

Once again the daily movement of bituminous all-rail has shown a falling off. This partly because of the railroads and their reduced consumption, but it is also due to cancellations being made by industrial plants all over the territory. There has been a lot of change in this respect since Dec. 1, and undoubtedly the mild temperature has had its effect. Then, too, a good many plants with Government contracts were rather expecting they would be permitted to keep up full operations until more goods could be accumulated. The Government, however, has made it clear that no consideration of the sort is to be shown, and many of the textile mills of Fall River and New Bedford have had to shut down for a day at a time because finished products are practically impossible to place and it would be a doubtful policy to continue heavy borrowing of money to keep plants in operation.

Meanwhile, a number of the Pennsylvania shippers are taking on what few orders they are able to pick up for spot shipment, and those who have first quality on their side feel optimistic over price developments when the restrictions are removed. Doubtless it will mean that a number of producers of inferior coal will simply have to close down for lack of orders. The market here, when it opens, is bound to be very discriminating.

At the New York piers there was such congestion, even of the better grades, that certain of the pools were embargoed. This applied mostly to mines in central Pennsylvania and in the Somerset regions. In territory adjacent to Long Island Sound trade is extremely dull. Stories are told of the great difficulty coal factors have in placing coal throughout Connecticut.

Anthracite—Receipts of domestic sizes continue to improve. The dealers are in fairly comfortable position, although price considerations and the uncertainty of demand the next three months lead them to be sparing in their arrangements for future deliveries. The result is that a cold snap like the present causes some uneasiness among retailers. They are apprehensive over the tie-up in New York and the fact that the same cold weather is likely to diminish the supply of stove and chestnut for New England. Those sizes are still in short supply and only a relatively small proportion is alloted to each cargo. Regulations as to broken and pea are now removed, but the demand from gas companies and from industrial plants is nothing like what might have been supposed. A very limited inquiry has developed for barley, but this is only spasmodic, for the steam situation in general would not permit heavy shipment of anthracite screenings.

The trade here is encouraged by reports that the movement of Philadelphia & Reading barges will soon be restored to Port Richmond, Philadelphia. Ample car storage, trackage and terminal facilities have been allowed to lie almost idle for months because of a fancy on the part of somebody in the Railroad Administration that Port Reading loading would very much increase the efficiency of tugs and barges. The distance is less, but every other element in the situation at port Reading contributes to long and expensive delay.

NEW YORK

Strike of marine workers has little effect on coal situation. Coal in retail dealers' yards sufficient for two weeks. Demand slow and "independent" product hard to move. Restrictions removed from egg. Bituminous market uneasy. Plenty of coal and manufacturers defer buying.

Anthracite—That New York is a "weather market" has been well demonstrated within the past week, as demand picked up slightly while the inhabitants shivered and fell off rapidly as soon as the weather moderated. The three-day strike of the marine workers had very little effect either one way or the other. Although no coal came from the loading docks, the retail dealers did not worry, most of them having plenty of coal in their yards for several days and some of them for two weeks. Their customers are also well prepared for the cold days.

The strike of the boatmen had its benefits, as well as its dangers for the coalmen. Some believe it proved to be the salvation of the shipper and dealer handling "independent" coal. The market was feeling groggy from the surplus coal on hand, and with dealers refusing shipments, fear was entertained that concessions would soon follow if any of the domestic sizes were to be moved. With the strike continuing a few days, agents and shippers predicted that the mines would have to suspend operations because of the embargoes placed on shipments, and that in the meantime the drain on the retail dealers would result in supplies being reduced so much that when the traffic on the bay and rivers was resumed demand would be urgent enough to take care of the coal at the docks at current prices.

For four days no coal was shipped from the railroad docks, but there was no anxiety on the part of the dealers who realized that the strikers would return to work before the coal supply had dwindled sufficiently to cause any fear of a coal famine.

Following a few weeks of inactivity and the refusal of dealers to accept shipments of "independent" coal when they were willing to depend upon shipments of "company" product, which they can purchase for 75c. per ton less than they are quoted for "independent" product, there was plenty of the domestic sizes available. This was not only true of "independent" product, but also of "company" product. Salesmen were sent out to arouse the dealers to the advisability of keeping their bins filled so as to guard against bad transportation problems, but they met with little success, many dealers preferring to take a chance rather than fill up on high-priced coal. Dealers are now counting the weeks and not the months before the winter will be practically over and the possibility of being able to make purchases below the current schedule.

This market may be relieved of much surplus coal now that restrictions as to shipments of egg, pea and smaller sizes have been removed and that these coals can now be shipped to such markets as may be found for them. The restrictions on anthracite shipments now apply only to stove and chestnut.

The steam coal situation is quiet. There is no movement and a rapid accumulation of the various sizes has followed. Individual shippers have met with some difficulty in moving their holdings and heavy concessions have been heard of.

Reports show that for the week ended Jan. 10 there were 5627 cars of anthracite dumped at the local docks as compared with 5546 cars the previous week, an increase of 81 cars.

Retail prices of coal in Manhattan and The Bronx advanced on an average 25c. per ton this week, as the result of the increase in wages of $6 per week and a nine-hour day secured by the drivers, yardmen and engineers of the dealers. This was followed by an increase in gross margins allowed the dealers by the Fuel Administration.

Bituminous—The bituminous situation continues dull. There is no demand and manufacturers and other large consumers are using their reserve stocks. Fortunately the market feels the after-effects of the holiday season, and production will not resume its normal pace until the middle of January, when the Church days following the Christmas holidays will be over.

Frequent labor troubles, besides the disinterestedness of workmen, interfere with mining operations; but under existing conditions the loss resulting has not caused any alarm because of the lack of coal. The result has been just the opposite. The

trade feels that the market is in better shape today than it would have been if production had kept up, and that instead of there being an entirely upset situation as regards prices the conditions are at least satisfactory, even though concessions for the cheaper grades are heard.

The only fear expressed at the danger of a prolonged strike of the marine workers was the shortage of fuel by the various traction and lighting companies, but the return of the men to work on Sunday obviated any curtailment of power supply, arrangements having been made for shutting off the heat in the cars of the traction companies.

The accumulation of stocks at the piers had become such that embargoes were placed against most of them. Fear that prices on the cheaper grades might be shattered by an over-supply of coal was not entirely removed by the stopping of shipments from the docks, but shippers early this week expressed the hope that demand might increase sufficiently to take care of much of the surplus.

Consumers are becoming more particular as to the quality of the coal delivered to them, and this accounts in great part for the present supply of the cheaper grades. The open season has been favorable to consumers and the demand between now and Apr. 1 is not expected to be favorable for heavy selling especially when it is believed that Dr. Garfield wil remove the price restrictions shortly. The demand for high grade coals continues to be greater than the supply. The change in bunker rules has had little visible effect on the situation.

The local dumpings of bituminous coal reported for the week ending Jan. 10 were 4996 cars as compared with 5451 cars the previous week, a decrease of 455 cars.

PHILADELPHIA

Anthracite market inclines to dragginess despite colder weather. Dealers advertise for business. Pea consumption below normal. Egg now allowed to be sold in any market. Stove and nut active. Spring outlook unpromising. Steam prices weak, with some price shading. Bituminous shows little change. High-grade coals scarce; others plentiful. Little buying.

Anthracite—It is growing more apparent each day that this market must have a continued cold spell to brace up the coal business. A light snow and a few comparatively cold days made some improvement and really kept the market together for a week longer, but failed to effect any permanent change. The indications are that dullness will once more overtake the dealers.

Numerous advertisements in the newspapers show the dealers need orders, but there are many in the trade who disapprove of advertising the fact. One of the largest retail companies by this means endeavored to acquaint the people with the fact that there would be an actual shortage if real cold conditions should arrive, as this market could only depend upon the tonnage alloted to it. It is believed this statement was only made to put the company on record in case the unexpected does happen, for the people certainly are not buying any more freely. It is also argued that with the present high prices the consumers will not buy until they actually need coal, especially if they are led to believe there is no scarcity and that they can obtain a supply on short notice.

It is not to be supposed that business is to remain dull until spring, as the winter is only young as yet; and if there should be an unusual snowfall or severely cold snap there would in all probability be a sudden demand, with many people all wanting coal at the same time. If instead of soliciting business now the dealer would allow the market to appear stronger, the householders would be more likely to buy gradually. It appears now that business is better with the suburban retailers, and it is a fact that their supplies are shorter.

The trade of the individual operators appears to be well cared for, while that of the big companies is more or less short of certain sizes. It is strange how the demand for pea coal has fallen off. Dealers report that their sales of this size are far below other years, but that the demand for chestnut has increased proportionately. Pea is free with most shippers and chestnut short with practically all. This market has always demanded an enormous tonnage of pea coal (which has been termed the poor man's fuel) for domestic use. It may be that with more money to spend the poorer class bought chestnut and find it more economical, and as the difference in price is less than $2 per ton, will continue to do so.

Egg coal is easy and no dealer can be found who is short of it. That it was becoming a problem to move is shown in the recent action of the United States Fuel Administration in removing all restrictions on it but price, even to the states barred since last spring from receiving any domestic sizes. No one will be at all surprised if the same action is taken on pea coal before the end of the month. It looks from this that the Fuel Administration is inclined to follow the line of least resistance, and as the season approaches we expect to see them remove the restrictions on one size after another, and then, as a final act before their retirement, cancel the regulations as to prices.

Stove and chestnut continue to have the call. While stove does not display the same strength as chestnut, still there is a most active demand for both sizes, for the reason that the stocks of these sizes are low in all yards.

The individual operators are not showing much concern as to how they can continue to market their product at their premium prices. No evidence of their cutting on the domestic sizes is obtainable, and it has probably not reached that stage as yet. They are hoping for weather that will carry them through until spring, for beyond that time no one will hazard a guess as to what conditions will be. Even the dealers are inclined to be pessimistic as to conditions after March, and there is a great deal of thought and discussion upon the subject. They feel at that time they will be unable to persuade a public that is tired of the coal question to purchase their winter's supply of coal in he spring and summer at a nominal reduction from the present circular. It is also being pointed out that any radical reduction in rates will surely bring on trouble with labor.

We have this week talked with some of the representatives of the largest mining interests, both company and individual, also with the most successful retailers of the city, and it is a fact that might as well be admitted that they all predict the dullest summer in the history of the trade. On the part of the operators it will be no surprise if they close down their mines and make repairs which have been neglected for the past two years.

We also gather that probably the Fuel Administration was never so popular as now, and that all hands would welcome a positive announcement that it will continue to dominate the coal trade until Apr. 1. Of course, this is because there would be no telling what would happen to prices if the business were suddenly returned to its old competitive basis.

As a matter of record we quote the delivered prices of the largest retail concern: Broken, $11.20; egg, $10.80; stove, $11.05; chestnut, $11.15, and pea, $9.45.

The steam sizes are in bad shape. All the trade seems to be trying to sell buckwheat. It can be bought from individuals at company circular and has been offered at 25c. less. The smaller sizes are comparatively weak.

Bituminous—The demand is still centered on the best grades of fuel, with the supply far from equal to the call. Industrial consumers are almost indifferent to taking any further supplies so long as they have such heavy stocks ahead and often stored in the most out of the way places, which they want to clean up before adding to their holdings. In addition these piles are on fire on account of having been stored too deeply.

Of course, those concerns requiring high grade fuels are actively in the market for more coal, but owing to the railroads continuing to take heavy tonnages, together with the shipments needed at tide for bunkering, it is very difficult to meet the demand on these grades. On the other hand the market is full of ordinary grades, and while salesmen are making many calls, they are meeting with but the slightest success in moving the coal.

BALTIMORE

The local market is flooded with coal, much of good grade, and takings fail to absorb. Embargoes declared against piers and some line points stopped. Prices break. Hard coal is plentiful also.

Bituminous—Coal is plentiful in the Baltimore district. The piers became so jammed several days ago that embargoes were placed by the railroads in an effort to clean up. At Curtis Bay, in order to release some of the rolling stock, coal was dumped by the rights-of-way in some cases. Line points for the most part were blocked also. Refusal to receive more coal was noted in numerous sections. Not only is it hard for the moment to dispose of immediate coal here, even though much better grades are now offering freely, but few industries will talk futures.

The representatives of numerous mines are now in the field for new connections. In such a market it is but natural that there has been at least a temporary break in prices, and coal is offering cheaper than for many months. As soon as business is shaken back to near-normal, however, the trade expects to see good coals all absorbed readily at fair prices. There is little thought that there can be anything like a permanent price for better coals much below the Government maximum, in view of the greatly increased overhead charges. Industries here report being pretty well stocked up by reason of the fact that their reserve depletion has not been so rapid on the present after-peace reconstructive basis.

Anthracite—The Maryland Fuel Administration has made the announcement that it has removed all restrictions on delivery of domestic coal. It warns, however, that there must be no move to raise prices above those last established by the Government agency. The move leaves the trade absolutely free as a whole to carry out the plan which had already been started by a part of the dealers to deliver the full third remaining undelivered on household orders. This at least where the consumers will accept the coal in full or in part, the mild winter and conservation moves having cut down the usual total consumption figures for the fall and early winter.

All sizes, with the exception of nut, are in liberal run, and pea and buckwheat are in too plentiful supply most of the time. With the return of supplies at times beyond their order needs of the moment the dealers here are hustling not only to get back old customers, but in many cases to hold those they picked up under coal famine conditions where regular dealer-connections could not supply even old-line customers. In this connection the Baltimore Retail Coal Exchange has issued an appeal to both dealers and the public to resume old relations of business as the fairest course. In many cases this will not be done, however.

Lake Markets

PITTSBURGH

Production adequate. Standard grades bring full price. Steel industry demands decreasing sharply.

Coal production in the Pittsburgh district last week was interfered with by celebration of the Greek Church Christmas, with its calendar 13 days behind the Gregorian, but the curtailment in production was not felt, as supplies are in general proving adequate to requirements.

The last of the coal allocations disappeared Thursday of last week, when those in favor of the Pennsylvania R.R. were rescinded by R. W. Gardiner, distributor for the district. The maximum taken for the railroad in a week during the period of control was 1152 cars. The movement now drops to normal proportions, and the railroad will get about 500 cars a week from the district.

Pittsburgh district steam coal has been fairly plentiful in the past two or three weeks, and there has been no decided change in the situation. Gas coal has continued decidedly scarce and consumers are kept busy securing sufficient coal for their requirements. Brokers report that in many cases they are still able to collect their full brokerage, beyond the set price, in the case of gas coal. Steam coal they are generally able to sell at the set price, securing a margin from the producer. On some off-grade coals there is shading, but in general standard grade Pittsburgh coal is bringing the full Government limit, frequently with brokerages in addition in the case of gas coal.

On account of the rather rapid slowing down in steel mill operations, which hardly began until this month, the demand for gas coal is likely to experience a great decrease, although public service companies will of course want as much as ever. Production of steel in December was actually at a greater rate than in November, but within a few weeks steel mill operations are likely to be at less than 60 per cent. of capacity, and perhaps at less than 50 per cent.

The market remains quotable at Government limits for standard grades: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

TORONTO

Business conditions back to normal. Plentiful supplies of all grades on hand. Shipments arriving promptly. Bituminous market continues quiet.

Business shows increased activity with the setting in of colder weather, and conditions are now practically back to normal.

There are abundant supplies of all grades of coal on hand to meet present demands, which are somewhat lighter than usual at this season on account of the great majority of consumers having laid in their supply. Shipments from the mines are received promptly, as there have so far been no transportation difficulties. The prices fixed by the government are well maintained, excepting that some brokers having large supplies of bituminous for which there is little demand are ready to make sacrifices to effect sales.

BUFFALO

World of bituminous coal. Consumers do not want it. Take long time to use up the surplus. Anthracite becoming more plentiful. Everything dull.

Bituminous—So odd that the world could be filled with coal before anybody knew it. It was all along declared that the shortage was going to be worse than ever before, and then, suddenly the deluge. Shippers say that it will be midsummer before the present surplus is gone, unless the production is cut down materially. That a heavy reduction of output is next to impossible is realized by everyone, so the prospect is for very dull trade. It is that already, so that the only hope is to hold the price where it is now. Operators say that they are not making profit enough to enable them to stand a serious reduction of the price.

Jobbers are doing a small business and feel themselves lucky if they are not loaded up with coal in Canada that they cannot sell. The chance of making a double profit there was so alluring that all but the few wary ones have been spending much time lately trying to get rid of the coal they shipped there. As fast as they are able they are giving up their Canadian offices and drawing out of that trade, for they see no activity in it for a long time ahead.

There has been some railroad stagnation, due to the slow absorption of the coal sent out from the mines, but the complaints on that score are not so great as they were. At the same time the railroads are not buying liberally, and most of them are refusing to help a shipper out where he has cars on track that have been shipped wrong or refused by the consignee. It does not look as if the trade was going to change for the better right away. An increased dullness and stagnation appears to be the rule. The operators are casting about and holding meetings to find a way of reducing production, for that seems to be the only way out.

Anthracite—The supply is adequate. After that there is little to say. The city is not yet able to understand how it came about in so short a time. It had been promised by the coal authorities, but the consumers were afraid that the territory to be covered would turn out to be so great that it would be a long time before everybody was satisfied. The supply was so large, though, that no complaint was heard from the time the lakes closed.

The prospect now is for a sufficient supply right along. Members of the trade see no reason for further shortage, even if the natural gas gives out, as it has to a great extent already. The plan is to cut out the gas from large consuming plants and turn it over to families that have no other means of heating. The fuel administration has reduced the price of gas-retort coke a few cents, but keeps up the price of anthracite, though the independent anthracite operators are already finding it difficult to sell their coal at full prices.

CLEVELAND

What No. 8 operators term "strong arm" methods of the railroads to batter down the price of railroad fuel has aroused much criticism and a determination to protest to Washington. Steam coal demand, while far from heavy, shows signs of improving; and with the mines still off because of the holidays, overproduction has been less noticeable of late.

Bituminous—Vigorous protest is to be made to Washington heads of the Railroad Administration against the attempts of Ohio carriers to break down Government maximums. Operators are not so averse to making a concession of 10 or 20c. a ton to the railroads as they are to helping insert a wedge that is bound to bring about reduced prices all along the line. In some instances railroads have gone a step farther than to inquire concerning a concession, and this has prompted some caustic criticism. Some was voiced at a recent meeting of Ohio operators at Cleveland, when, among other things, John Moore, president of the Ohio Mine Workers, declared that the mine workers will not stand for a cut in their scale; and operators were firm in their conviction prices cannot be reduced unless railroad rates or wages are reduced.

Real winter weather has arrived at last, and this has increased, probably by one-third, the domestic demand for bituminous. More and more buying has been done by steam-coal users, although they have been attempting to satisfy urgent requirements only but the time draws nearer and nearer when considerable buying will become imperative. Except over the holidays, when inventory was taken, few industries in northern Ohio have suffered greatly from a lack of market, and stock piles have melted a great deal faster than expected.

The matter of price continues to open the doors to many statements, but Government prices seem to be holding with surprising strength. Many small domestic dealers are selling stripping coal at quite reduced prices, and a fair amount of standard No. 8 coal is going to steam coal buyers, quietly of course, under the maximum. If prices do not break before lake coal again is sold, operators believe they will have been tided over the worst. Indeed, from the standpoint of both demand and price, many operators believe steady improvement is bound to set in from the middle of January on.

Car supply accorded members of the Pittsburgh Vein Operators' Association of Ohio in December averages 78.20 per cent. as against 79.65 per cent. in November. In December lost production, due mainly to car shortage, amounted to 322,900 tons; in November it was 341,550 tons. For the week ending Dec. 31 the car shortage averaged 23.86 per cent. and lost production was 59,700 tons. Shipments by members of the association amounted to 3368 cars in the week ending Dec. 31. The week previous shipments were 4195 cars.

Anthracite—Receipts are now the largest of the season, and are growing larger from week to week. Anthracite is not at all plentiful, but for the first time in practically a year retailers are advertising they have an ample supply.

Lake Trade—The steamer "Edwin N. Ohl," of the Becker fleet, Cleveland, has loaded the first lake cargo of 1919. At Ashtabula she took on a load that was mainly coal in transit on a lake shipper's account when the 1918 season ended. Reports from the upper lakes are to the effect coal is moving off the docks very slowly, and dock piles in the spring are likely to be larger than in the spring of 1918 or 1917. This may cut the 1919 lake movement to as low as 26,000,000 tons, some lake shippers fear.

DETROIT

Because of heavy stocks in the local market, Detroit jobbers and wholesalers find it difficult to interest buyers in bituminous coal for either steam or domestic use.

Bituminous—Jobbers and wholesalers operating in the Detroit market say that disappointing lack of success attends their efforts to interest either the users of steam coal or the retail dealers in their offerings. The volume of business is described as far short of normal, though figures are apparently unavailable to show the exact disparity compared with previous years.

The reason for the aloofness of buyers is found by the jobbers in the presence of large stocks of bituminous in the reserves of steam-coal users and the stock piles of the retailers. In many cases the heavy supplies are occasioning unrest to the possessors as well as serving as a check on business. Jobbers hear that the manufacturing plants are having considerable trouble with their fuel, because a large part of it consists of a poor quality of coal that was sent into Detroit a few weeks ago to replace stock of a better grade that had been zoned out of the city.

The heavily stocked retailers also are suffering much anxiety. They too have a lot of the low-grade coal in stock, and some of them are holding a considerable amount of mine-run and slack, which was bought when the Fuel Administration, giving warning of a probable shortage, advised the purchase of any form of coal that could be obtained. Because of the high temperatures that have so far prevailed, retailers have found their customers dilatory in placing orders. The fact that coal of better grade, in lump and other sizes better suited for household use, is now coming into the market freely does not tend to brighten the outlook for the retailers, who face the possibility of finding a large part of their stock still on hand when spring comes.

Anthracite—Moderate temperatures have afforded opportunity for domestic consumers to use anthracite sparingly, with the result that supplies are better than anticipated. There remains, however, a large potential demand, which cold weather would stimulate and which would speedily clear the market of the anthracite on hand. The situation created by the deficient supply of anthracite has been greatly improved from the viewpoint of the domestic consumer by a large increase in the supply of coke and by a reduction of $1 a ton in coke prices, ordered by the state fuel administrator.

COLUMBUS

The colder weather of the past ten days has stimulated the retail trade. Steam business is still slow, and little tonnage is moving. Some price cutting, especially in steam grades, is reported. Considerable West Virginia coal is arriving in the local market.

The feature of the coal trade in Ohio has been the larger volume of West Virginia coal arriving, which has the effect of reducing the movement of Ohio-mined varieties. The West Virginia shippers are cutting quotations below the Government figures. This has not yet demoralized the market, as the larger Ohio operators are holding firm, preferring to shut down rather than shade quotations. This applies more particularly to steam grades, although there is a large amount of domestic sizes arriving from West Virginia.

The lower temperatures have stimulated the retail trade and dealers generally are now busy making deliveries. Retail stocks are still pretty large, and the activity induced by colder weather has not been reflected on the operating and distributing ends of the business to any extent. Consumers are asking for the fancy grades such as Pocahontas and splints. Retail prices are generally well upheld and little cutting is reported. Hocking lump sells at $5.75 and other grades at corresponding levels. Householders generally have larger stocks than ever before, and consequently the rush because of the cold wave is not so pronounced as in past seasons. Anthracite is practically out of the market and there is little domestic coke to be had.

The steam business is slow and reports indicate large stocks in the hands of consumers. Purchasing agents for manufacturing plants are not disposed to buy under present unsettled circumstances. The policy followed is to use up surplus stocks before buying more. Public utilities are well supplied, and the same is true of public institutions. The Michigan market is still overstocked and little relief is expected in that quarter.

Production is now to a low point, principally because of lack of orders. Some car shortages is also affecting the output in certain districts. It is estimated that the production in the Hocking Valley district has been about 40 per cent. and in Pomeroy Bend about the same. Eastern Ohio has had a fair run, with about 50 per cent. production.

LOUISVILLE

Colder weather improves domestic demand slightly, and demand from small heating plants. General steam demand sluggish. Low grades hard to sell at any price.

Slightly colder weather has resulted in some small improvement in demand for small lots of domestic, but domestic consumers are so thoroughly stocked that very little demand is looked forward to until the latter part of February. Zero weather has not been experienced as yet, and consumption for the fall and winter to date has been considerably under normal.

The local steam demand is practically nil, as industrial concerns are using up stocks on hand, which were stored last summer or fall. They are not buying until present stocks are cleaned up, when they expect to enter on a competitive market basis. Neither mine-run nor nut and slack is in any demand, and fine screenings are dull.

Many mines throughout the field are down at the present time and have little expectation of resuming until they can dispose of coal on board cars and secure additional orders. Wagon mines are rapidly dropping out of competition, as the big selling organizations are scouring the market so thoroughly, and have so much coal to dispose of that there is no room for the wagon mine.

Labor and car supply are showing a general surplus all over the state at the present time. Mines are having no trouble in getting all the labor desired, in spite of layoffs, as there is not the heavy demand previously experienced, and the closing of wagon mines is helping the situation.

River coal shipments during the past few days have been small, as the Licking, Big Sandy and Ohio, as well as other rivers, have been at flood stage, too high in fact for successful handling of tows due to heavy current. For a time it was thought that mine operations would be interfered with. Some railroads were under water, but a

freeze checked the rise and no danger is now feared.

The market as a whole is firm, with few reports of price cutting of any moment. The big operators are endeavoring to hold up prices, and locally the retailers are working nicely.

BIRMINGHAM

Severe weather conditions and shortage of supply create strenuous demand for lump coal. Steam also in good demand from all classes of consumers. Mine workers slowly returning to work and production far below normal.

The local market is experiencing the strongest demand for domestic coal in the ten months. There is scarcely any coal in any of the yards in this district, and brokers and distributers are being besieged with requests for more liberal shipments, while consumers are camping on the trail of the dealers. A survey of the yards in old Birmingham last Saturday showed a total of less than 300 tons of domestic coal on hand. The severe weather of the past few days, when the thermometer registered uncomfortably close to zero, found many of the poorer classes and some of the better element without coal and able to secure only a nominal amount, if any at all. Cities and towns throughout the state are without any stocks.

Inquiry for steam coal is also good and in excess of the production at this time. The demand is general, railroads, mills, industrial plants and public utilities being the most urgent buyers. Some Illinois coal has been diverted to the Mobile trade during the past week.

The output at the mines is only about 50 to 75 per cent. normal, and the situation is improving very slowly. There is still some sickness in the camps, but this is responsible in only a small way for the shortage of labor and the irregularity of the men in reporting for work. The weather conditions of the past week had a very disastrous effect on coal production, accentuating the labor shortage and crippling the machinery at the operations. The output for the week ending Dec. 28 was the lowest yet recorded by the Government representative here, being 109,179 net tons.

Coke

CONNELLSVILLE

Coke supplies increased but market still steady. Labor performance improved.

An easier tone pervades the whole coke situation, as production is showing an increasing tendency, with better labor performance, and the blast furnace requirements are tending to decrease. The Fuel Administration's control of prices continues, and it is established that the control will continue to Feb. 1 and quite possibly until Apr. 1, the end of the coal year. It is understood that the Fuel Administration will give at least a fortnight's notice before relinquishing control. This advance notice has been urged by the blast furnace interests that have contracts requiring negotiation in case the Government price disappears. Other coke contracts provide that the Government price shall continue to the end of the contract in the event of the control being removed. Coke operators who have the latter form of contract regard its as favorable, but the operators who have contracts involving negotiation are satisfied with their form also. They maintain that if the open market should decline much below the Government level there would be difficulty in enforcing the $6 contracts, as furnaces would be disposed to blow out and the contracts would not operate, since they are simply "requirement" contracts.

Despite all the holidays, both the regular holidays, on the Gregorian calendar and the other holidays, 13 days later, on the Julian calendar, some coke operators report that their labor supply began to improve with the week beginning Dec. 23 and that conditions now are much more satisfactory than at any time since the beginning of the influenza epidemic. There are not only more men on an average each day, but they are more disposed to work, realizing that their jobs are no longer absolutely secure.

Practically no furnace coke is being offered on the open market, and probably but little would be absorbed if offered, unless at a cut price, as the furnaces are fairly well supplied. One stack resumed operations last week after being banked about two weeks. Offerings of foundry coke are of moderate volume, and sales are not altogether as readily effected as formerly, although there is no shading except to middlemen. The market remains quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30 per net ton at oven. Screenings from old dumps sell with great difficulty, and $5.25 is the highest price obtainable, the Government limit having been $5.50.

The "Courier" reports production of coke in the Connellsville and Lower Connellsville region in the week ended Jan. 4 at 253,980 tons, an increase of 21,790 tons, and shipments of raw coal at 173,568 tons, an increase of 45,853 tons.

Buffalo—The demand is not so heavy as it was, but a recovery is looked for as soon as the manufacturing trade generally is adjusted; for the need of iron in the country is as great as it was and the supply is small and many staples are hard to get at all. On this account the lake vessel owners are looking for the same big flow of ore down the lakes next season as during the one just past, and at practically the same price and same rate of freight. Fuel coke is dull, even when it competes with anthracite, as it is used for the most part when anthracite is hard to get or where it can cut the price slightly.

Middle Western

GENERAL REVIEW

Cold weather stimulates demand for domestic coal. Steam coal users not purchasing. Question of prices now to the fore.

The Middle West has enjoyed for the last five or six days its first spell of really cold weather, the temperature in some instances going down as far as ten to sixteen degrees below zero. This change in the weather has not brought about any great activity in the market. It has, however, stimulated to some extent the purchasing of domestic coal, especially through Iowa, northern Illinois and Wisconsin. The purchasers of steam coal are continuing to hold themselves aloof from the market until such time as they adjust themselves to the new conditions, which they will have to face. In the meantime, they are not burning as much coal as usual on account of decrease in manufacturing, and they are even less interested than they were two or three weeks ago in purchasing any kind of steam coal.

The recent cold snap, however, has to some extent increased the purchasing of coal on the part of the railroads. We do not mean that they have gone into the market and placed new orders, but they have instructed various operators to forward coal a little more rapidly than heretofore on the orders they have already placed.

The price question in the Middle West is getting to be a more important one every day, and many conjectures are made as to what the probable future of this question will be. As a matter of comparison, take a coal from the Springfield district of Illinois and a coal from the Franklin County district of the same state. These two coals cost practically the same at the mines, and one is a vastly superior product to the other, for nearly all purposes, yet they sell for exactly the same price at the pit mouth. This state of affairs, under ordinary conditions, will not stand to reason, and as a result some change will have to be made. A man is not going to buy a cotton coat if he can buy a woolen one for the same price.

There has not been any radical change in market conditions in the past week, except perhaps the demand for steam coal has decreased, if such a thing is possible. The operators, furthermore, are not looking for any change until at least another month, or perhaps the first of April.

The labor question is being discussed with more and more frequency and seriousness as we approach the spring, and it is freely conjectured that this labor question will be a more and more important one, so far as the coal consuming public is concerned, before next April.

CHICAGO

Retail trade stimulated by cold weather. Anthracite situation clearing up.

The retailers in Chicago have been buying a little more coal than usual. The intense weather we have had for the last six days seems to have stimulated trade to a great extent, and they have been buying rather freely as a result.

The United States Fuel Administration at Washington recently made a ruling to the effect that Eastern domestic coal could be shipped to points in Chicago, or anywhere in Illinois, provided the dealer got a permit covering such shipment. This permit, according to the Fuel Administration orders, could be obtained from the State Fuel Administrator. Since this ruling was made known, a great many retailers applied to the State Administration, but were told that no permits had been granted, or would be granted for some time, as it was up to Illinois to reduce her own surplus storage coal before any of the higher grade Eastern product could be used.

The anthracite situation seems to be clearing up, as the average householder has no trouble now in having his order for more coal filled at his convenience.

ST. LOUIS

Warm weather prevails with no steam demand and a light domestic call. All sizes on all grades heavy. Prices gone to pieces. Country orders fair. First anthracite coming in.

A warm wave after a few days of cold weather maintains a condition that is hard to describe. The cold weather was of such short duration that it had no effect on prices. There was a noticeable movement over what was considered normal, but it faded away with the return of summer weather. The oldest coal man cannot remember a winter such as this. The winter of 1877-78 was a mild one, but nothing in comparison with the present.

There is a fair country business on domestic sizes. This is mostly for Carterville, although a fairly good tonnage of Mt. Olive is going out. The outside steam inquiries are light. Locally there is an overloaded steam market from all fields, and there is no prospect of relief in sight for steam. Even if cold weather comes there will be a greater production than the local market could absorb under the most strenuous condition, for the increased call for the larger sizes would be just twice what it is now, if not more.

The Standard field is in bad shape. Many mines are idle because they cannot move screenings, or it may be nut or egg at some other operation. There is apparently a surplus of all sizes when the entire field is considered.

Cars are not plentiful on the Illinois Central R. R., although the movement is fair. On other lines there is a good supply of equipment.

The Mt. Olive district is beginning to feel the effect of the weather. The mines are idle, and there is a general slowing up, with plenty of unbilled coal on track. There is, however, a good movement from this field into country districts, and Chicago and the north continue to take liberally, everything considered. There is a light movement of Standard north, with most of it going to Chicago.

The Carterville and Du Quoin fields are faring very much alike. There is a surplus of coal, even though the railroads are taking liberally on their contracts. Domestic orders get prompt shipment now, and the steam demand is about equal to the supply. There is a marked preference shown for the mines that do not assess a preparation charge for a doubtful preparation. The buyer in this market feels that the coal is no better prepared than in pre-war times, and it had to be clean then to find a market. The opinion is that the Administration permitted itself to be subjected to a strangle-hold and had this jammed down as a sop to a certain class whose patriotic spirit resembled a love of dollars more than a love of country.

The Williamson County field is shipping heavily to the south, but the St. Louis tonnage from Williamson and Franklin County, as well as Du Quoin, are light. There is a good storage supply of this in St. Louis.

Little Arkansas moving in and those who have it in storage are going to take a loss of at least $1.50 per ton. This because on Jan. 7 the ban on anthracite egg for St. Louis and the west was lifted, and about 100 cars were ordered, all that was available then. The mine price on about half was $5.22 net, and a dollar more on the remainder. With the freight of $5 gross this made a St. Louis price of $9.70 and $10.70; adding a $2.50 gross margin for the retailer makes it $11.35 and $12.35 to the consumer. This size, when it ceased to move in last spring, was selling at $10.75.

The coming of anthracite shot the coke market all to pieces. Byproduct coke came down to $12.35 from $13. It will be hard to sell at that. The gas house market is slower, but is easy.

Standard prices on the market are: 2-in. screenings, $1.30 to $1.50; nut, $1.75 to $1.85; egg, $1.75 to $1.85; 2-in. lump, $1.60 to $1.75; 6-in. lump, $1.75 to $2.25. Mt. Olive is breaking slightly, although the big producers are standing pat. Carterville stays up pretty well to the Government maximum.

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.30	New Orleans	$0.38½
Buffalo	.17	New York	.27
Chicago	.27	Philadelphia	.24½
Cincinnati	.23	St. Louis	.24
Cleveland	.17	St. Paul	.49½
Denver	.99	Pacific Coast (all rail)	1.25*
Kansas City	.59		

Note—Add 3% transportation tax. * Minimum carload, 80,000 lb.

COAL AGE

Volume 15 New York, January 23, 1919 Number 4

Coal, Railroads and the Government

NOW that there seems to be a strong indication that the five-year extension of Government operation of the railroads will become a reality, a problem of great significance confronts the coal industry as a whole. During the war period, the attitude of the operators and middlemen (however they may have designated themselves) was one of patriotic resignation of personal interests to the national welfare. Competition was succeeded by a generous cooperation in all national policies. Furthermore, the demand for fuel so exceeded the supply in those strenuous days, that the sole anxiety of both producer and distributor was simply to increase production.

With the hectic days of war over and the first steps in the nation's reconstruction program being taken tentatively, the coal industry must watch and prepare itself for such a peculiar situation as the probable five-year extension of Government operation of the railroads is certain to bring about.

Whether Government operation of the railroads will prove advantageous to the country or not is not pertinent to the present discussion. What is of considerable importance, however, is how it will affect the coal industry. The railroads are the largest individual consumers of coal, and they have always been catered to because of their enormous consumption. In a certain sense they have been the barometer of the coal trade as the steel business is of the country's whole industrial life. Now that these large individual customers are about to be welded into one gigantic customer, with a purchasing power that can shape the destiny of the coal industry as surely as if it were a majority stockholder, how prepared is the coal industry to adjust itself to this new situation?

Do the policies which all producers (and particularly those mining locomotive fuel) are laying down for future business expansion include a careful consideration of the potential part that the Government may play? Any sort of stability and any return to the prewar basis of doing business in the coal industry is out of the question until the Government's action in the matter of the railroads and its attitude toward the coal trade are definitely settled and outlined. The new order of things is bound to alter and destroy many of the established relations and customs of the trade.

Perhaps those who have most cause for alarm are the middlemen. Will their functions and services be entirely eliminated by the Government when purchasing coal for the railroads? This gives rise to several other germane questions: Will the Government continue to employ the regional purchasing committee plan in supplying the railroads with their fuel requirements, as it has signified its intention of doing, or will it at some not far distant date have the purchasing done by a central committee for all the railroads? Will prices be hammered down by the mailed fist of concentrated buying until the margin of profit is so reduced that invested capital will no longer be interested in coal mining?

All this, of course, as already intimated, applies principally to producers of the locomotive grades of coal. Producers of the steam grades will not be so materially affected, though they are certain to meet keener competition in that many producers of the locomotive grades will branch out into their field, where investments will be more remunerative.

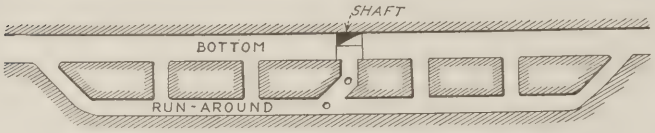
If producers feel that they can dispose of their product in foreign markets to better advantage than at home, and can secure this foreign business, will the Government restrict the export of those grades of coal which it requires? Is it not possible that Government ownership may be extended to the coal mines within a short time, particularly to those mines which will be called upon to supply the railroads?

Regarding the situation of the New England railroads, will the Government retain enough boats of its Emergency Fleet to move the coal from the Southern fields to the New England ports? Or will it endeavor to supply its New England requirements by rail, to the detriment of all other New England coal consumers who will be obliged to take tide shipments?

The problem is so vast and so full of possibilities that the further one dips into it the greater it seems to become; and one soon is lost in a vortex of questions and still more questions. These, however, must all be given due attention, and the sooner the trade realizes this and makes ready to meet and solve each question as it arises the less panicky will be the work of reconstruction and adjustment. Foreign trade looms up as a solution to many a vexatious difficulty, and it is certain that the United States will in the next few years make tremendous strides in the conquest of foreign markets. How will this affect the coal industry?

Readers of COAL AGE are invited to discuss the matters touched on in the foregoing article, as upon the proper answers to the questions asked rests in a great measure the future prosperity of a great part of our industry.

IDEAS AND SUGGESTIONS



Sump-Cleaning Tunnel Proves Successful in Several Illinois Mines

BY H. GOODNOW
DuQuoin, Ill.

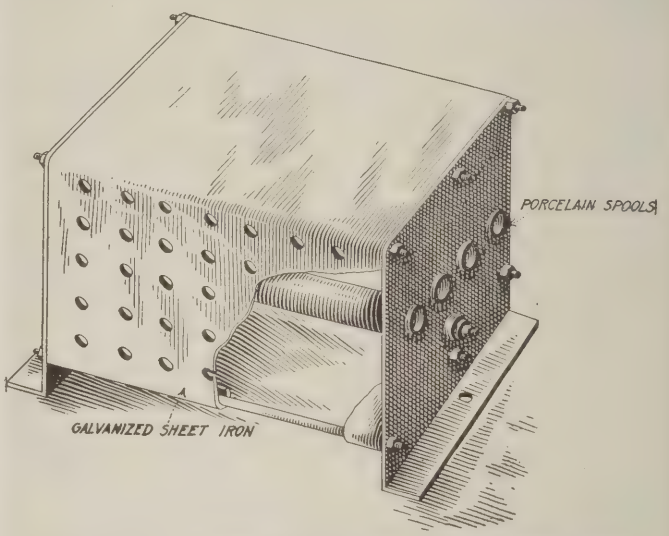
Cleaning coal out of the sump at the shaft bottom is a job for which there is ordinarily little competition, since this work combines a maximum of work with a minimum of comfort. More serious than this, however, are the frequent delays to hoisting arising from a car running into the sump or from reckless hoisting prematurely filling up the sump with spillage until the cage cannot land.

In order to provide easy access to the sump for the quick loading out of spilled coal, a tunnel driven from the run-around to the sump bottom and large enough to pass a car has proved a big success at several Illinois mines.

To secure a good grade and curve it has been found advisable to start in the run-around at such a point

METHOD OF BUILDING TUNNEL FROM SUMP

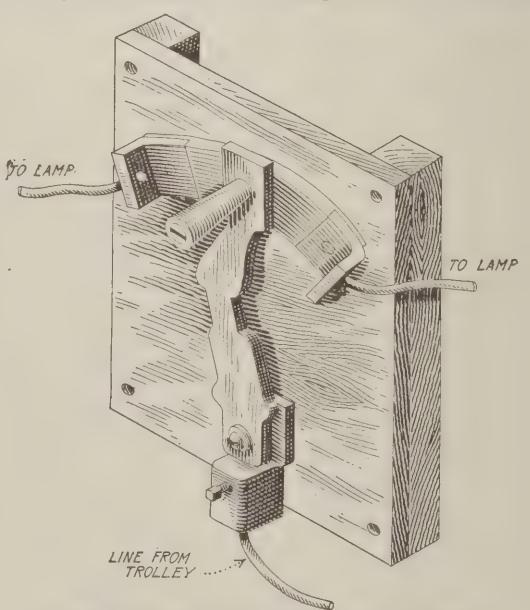
that a 45-deg. slant will come opposite the sump in the center of the pillar, from which place the tunnel may be driven straight for the sump bottom. After a little grading a track can be laid and a car passed through this tunnel to the bottom of the sump and loaded at any time. A locomotive in the run-around can then easily pull this car out with the aid of a short cable.



At one southern Illinois mine such a tunnel saves 16 hours' work each night. It has also enabled the cleaning up of a wreck, when two loaded cars had gone into the sump, to be accomplished in 6 min. To do this a chain on the bottom of the cage was used to turn the cars over and empty them, after which they were raised and swung to their place on the track. In the meantime two cars in the sump-cleaning tunnel were loaded out and the mine resumed hoisting in what was really record time.

Automobile Headlight Proves Serviceable for Use on Mine Locomotives

BY J. J. NOLAN
Linton, Ind.

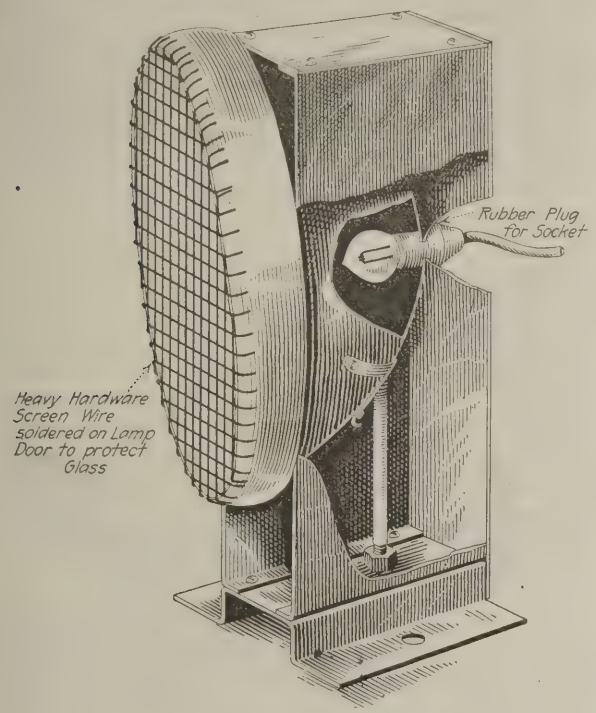


The illustrations shown herewith are of a locomotive headlight, resistance and switch that has been placed in service on more than thirty locomotives in sixteen mines belonging to the largest coal company in Indiana. These changes were made after the upkeep of carbon filament and luminous arc lamps for locomotive use had been found excessive due to the rough treatment given them.

After completing the lamp proper (which is one used on a popular make of automobile), the question of the proper size of wires, length, etc., that would carry the current safely received attention. The length finally adopted and the size and ohms per 1000 ft. (using a 6- to 8-volt, 2.5-amp. bulb on a 250-volt circuit) are

DETAILS OF RESISTANCE USED WITH HEADLIGHT

as follows: Size, 0.025 in.; number of feet, 110; ohms per 1000 ft. 820. This was found to carry the necessary amperage, as the lamps were tested for 300 hour continuously, the same bulb being used without change.



SWITCH FOR USE WITH HEADLIGHT

To use the lamps in series would have required less resistance; but being on series would mean to burn the lamps on both ends of the locomotive at the same time instead of only one when it was needed.

The base of the lamp is of a suitable size, and it is drilled to fit the threaded holes in the locomotive frame

that formerly held the common arc or luminous arc lamps. Two $\frac{5}{8}$-in. holes on $10\frac{1}{2}$-in. centers were drilled in the base. The light given by the lamp is satisfactory when the drop in voltage is not too great. If kept clean, and in proper repair, the lamps give little or no trouble. Furthermore, when it becomes necessary to change certain parts the renewals can be made at comparatively little expense.

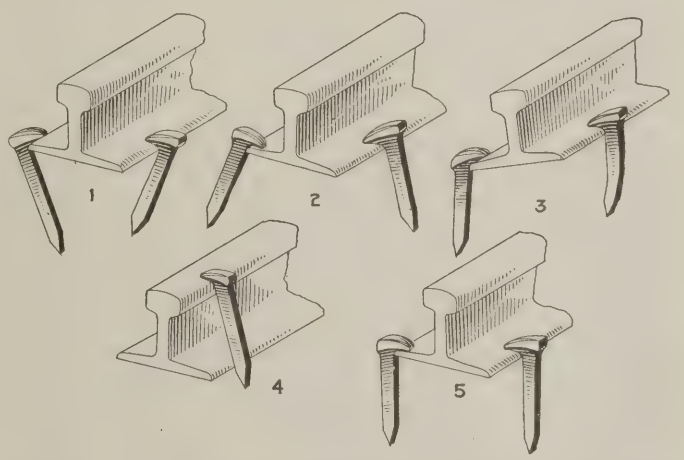
A lamp of higher voltage would have required less resistance, but the filament would have been lighter,

DETAILS OF COMPLETED HEADLIGHT

and due thereto the lamps would have been unable to withstand the heavy jars and higher voltages to which they are subjected near the shaft bottom or when in proximity to the source of power.

The resistance requires a space $9\frac{1}{8}$ x $7\frac{1}{8}$ x $4\frac{1}{2}$ in. The resistance tubes, which are of porcelain threaded on the outside and measure $7\frac{1}{2}$ in. in length, can be procured from a well-known firm that manufactures resistances for various purposes. The porcelain bushing and terminal or binding post can be secured from the same firm. A durable switch that will answer the purpose may be made from spare parts of mining-machine contacts and brushes, or from fingers mounted on a fiber base. This material can be found in almost any mine repair shop.

Observations of an Old Trackman on the Proper Driving of Spikes*



In my younger days I often watched mine trackmen lay switches and straight track, and it was really amusing to see how they distorted the spikes in driving them. Fig. 1 shows the manner in which spikes are often driven. One trackman assured me that he drove the spikes in that manner so as to keep the rail down on each edge. This is a poor way to drive a spike, as it is not so tenacious as when driven straight, and the head is likely to be broken off. Fig. 2 shows where the spikes were driven slanting. When the head got down to the rail base only the edge of the head touched the rail. This also is a poor method.

Fig. 3 shows a rail that is sprung. Here the trackman drove the first spike down, then drove the second spike and bent it before it was half driven, in order that the whole of the head might have a bearing on the rail. When the spike gets down to the base, the trackman gives several heavy blows, seeking to "pull the rail down." This invariably pulls the head off the strike and is obviously a poor method. Fig. 4 shows a spike started too close to the head of the rail. As the spike is driven past the rail head it is bent and weakened. It is likely to bend in against the web of the rail after which, of course, it is useless. It must be pulled out and another put in.

Fig. 5 shows spikes driven correctly. It will be noticed that the spikes are started perpendicularly. In consequence the head of the spike has a full bearing on the base of the rail.

Very few trackmen notice it, but a careful observation of a spike will reveal the fact that its head is sloping on the under side, and when the spike is driven tight the entire length of the head will fit into the contour of the rail at the point of contact.

On account of the present high cost of material, we should exercise great care in the driving of spikes. They are not only expensive, but at times it is practically impossible to get them. The waste in spikes is enormous. It often makes a man ask: "Where do they

FIGS. 1 TO 5. DIFFERENT METHODS OF DRIVING SPIKES

all go?" I believe that if they were driven straight in the first operation and handled with a little care we could recover twice as many as we do.

Look about your track in the rooms and headings, and notice the freakish appearance of things that once were spikes, and observe what the chances are for their being reclaimed, and you will never ask anybody again "Where do the spikes all go and why?"

*From *Our Own People*, Davis Coal and Coke Co. publication, January number.

Nearly nine-tenths of the total estimated coal deposits of the United States, or about 3,550,000,000,000 tons, are stated to lie at a depth not exceeding 3000 ft. below the surface.

FIG. 1. COAL-LOADING MACHINE THAT DOES AWAY WITH DOUBLE SHOVELING AND COAL CARRYING

Mining Coal by Machinery

By N. D. LEVIN
Columbus, Ohio

SYNOPSIS — *Many attempts have been made to load mine cars with coal from the face by machinery. In order to obtain the best results from such equipment it is necessary to lay out the mine in such a way as to adapt it to operation by means of such machines. Then and only then will the best results be obtained.*

MUCH money and effort have been expended in past years in an attempt to load coal by means of machinery. Nevertheless an insignificant percentage of the coal mined is handled by loading machines; more than 99 per cent. is still loaded by shovel. The reason for this is that in many mines there exist unfavorable conditions, which may be enumerated as follows: A vein that is too low; the roof may be poor, and there may be dirt seams in the coal; roomnecks are narrow; not enough coal is obtained from each room; coal cannot be shot down on the floor in shape for the machine to pick up without breaking to such an extent as to seriously reduce the percentage of lump; conditions may be such that empty cars cannot be supplied without causing delay to the machine.

The machine shown in Fig. 1 has been developed with the end in view of using it in mines having conditions like those mentioned. This machine is light (it weighs about one ton), can be handled by one man if necessary, but more conveniently by two. It can be made for almost any height of bed, provided there is sufficient room between the top of the car and the roof for the lumps to pass.

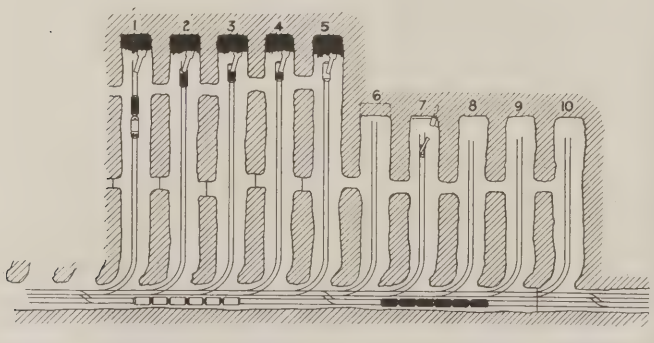


FIG. 2. SYSTEM OF MINING SUGGESTED FOR ADOPTION WITH COAL-LOADING MACHINES

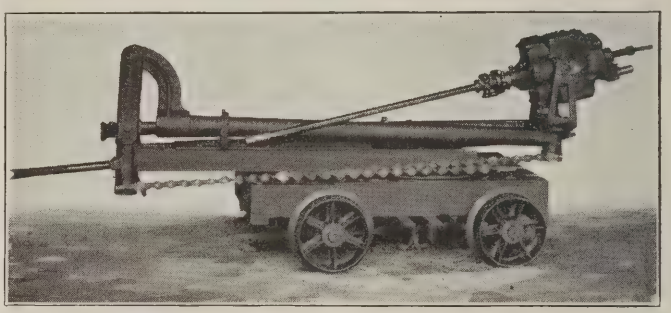

FIG. 3. DRILL MOUNTED ON TRUCK CAN BE MOVED TO ANY PART OF FACE BY ONE MAN

The machine does not pick up the coal from the floor. Where the shooting is done during working hours, it saves work to shoot the coal directly onto the loader, and thus several tons often can be obtained without any shoveling whatever. The coal can also be pulled down from the face directly onto the loader, and large lumps rolled on, eliminating some work in breaking up, and at the same time giving better lump coal. If this machine is used in a systematic manner, the regular output of the mine can be obtained from a greatly reduced mining territory.

Following is an example of a mining system which may be employed where conditions are suitable, and something along similar lines may be worked out for other conditions. The assumptions are: Height of coal, 6 ft.; width of rooms, 20 ft.; undercut, 7 ft.; capacity of mine cars, 4 tons. It is preferable to have the track in the center of the rooms. A mine car of 4 tons capacity is, of course, larger than is found in most mines, but it is recommended that large cars be used with loading machines in order to facilitate the gathering. There are assumed to be 10 rooms in the system.

Referring to Fig. 2, five rooms—Nos. 1, 2, 3, 4 and 5—have the coal shot down, and a loading machine in each. There are two men with each machine. Rooms 6 to 10 are being undercut and drilled. It is assumed that the shooting is done during working hours and the coal is not shot down until the loading machine is in position. There being ten rooms in the system, rooms 6 to 10 would be undercut and drilled, say in the forenoon, and rooms 1 to 5 would be undercut and drilled in the afternoon.

From each room undercut there would be obtained about 34 tons of coal. It is found that two men can readily load this amount in 4 hours with the assistance of the machine; therefore, rooms 1 to 5 would be loaded in half a shift, while the other rooms are being prepared.

The machines are then moved, and rooms 6 to 10 are loaded out in the other half shift. It will be noted that the ten rooms would give about the right amount of work to keep two men with a shortwall machine busy undercutting. It would also keep a gathering locomotive busy handling the cars for the five pairs of loaders. The cars being large, there would be only nine cars required from each room, or 90 cars per shift. It should not be much trouble for a gathering locomotive to bring in the requisite number of empties expeditiously to the five loading machines.

If the cars were smaller, there would be some question as to one gathering locomotive being able to serve all the loading machines promptly. We may go further; if the cars were, say, only one-ton capacity, I do not think it would be possible by means of any system to handle the cars so that the machines would not be delayed; therefore I mention this, because the importance of large cars has not been fully appreciated in the past where loading machines have been tried.

FIG. 4. PIPE SCREW POSTS

Figs. 3 and 6 show a drill mounted on a truck in such a manner that it is never necessary to detach it therefrom. It is suspended on a double hinged arm so that it can be moved to any part of the face by one man, without any heavy lifting. By means of this equipment one man could do all the drilling and assist in cleaning up, timbering, and other like work.

It is also important that the track be laid in the rooms before the machines are moved in. Sections of track of convenient lengths should be made up permanently, complete with steel ties, and have a fishplate connection so that all that is necessary is to drop the sections into place. About three sections, each the third of a length of rail, should be a permanent fixture for each room. When the third section has been used, all three will be taken up and replaced by a length of rail. In this manner it will only take a few minutes to extend the track, and this would not delay the machines.

Unless the roof is exceptionally good, there should

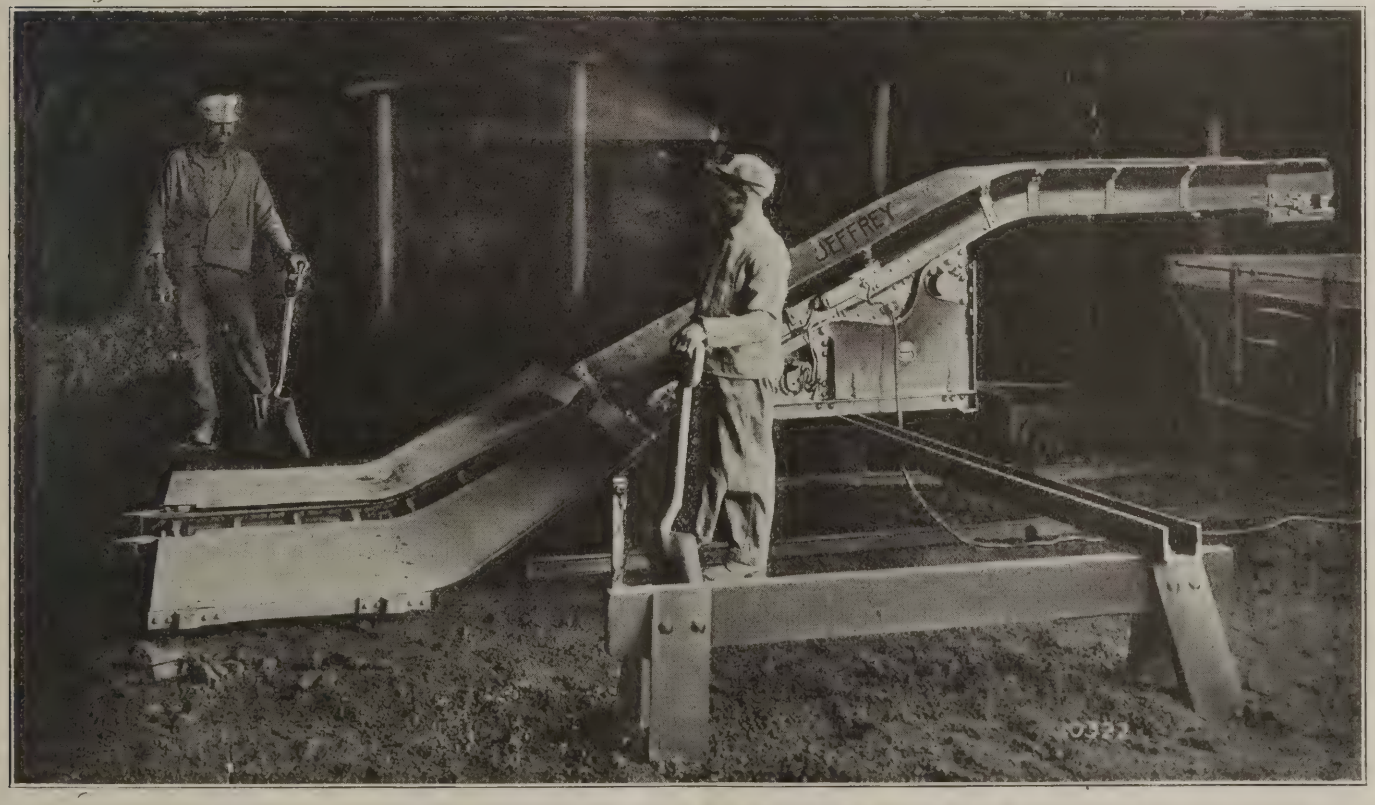

FIG. 5. TWO MEN ONLY ARE REQUIRED TO MANIPULATE THIS EASILY PORTABLE COAL-LOADING MACHINE

also be provided as permanent equipment for each room a few pipe-screw posts such as shown in Fig. 4. A post like this can be set in a fraction of a minute, whereas it often takes 15 min. or more to go and hunt up a wooden post and set it; and if the men have to go and hunt up an ax and cut the post to length, it may take half an hour.

To make a success of loading machines in a mine, every precaution must be taken to keep the machines working. If such precautions are not taken, the machines will be idle a great part of the time. If a miner is simply given a machine, he will spend more than half of the time in drilling, shooting, cleaning up, setting posts, laying track, taking up bottom and "fixing" his carbide lamp. These things should be done for him.

The last item, "fixing his carbide lamp," may seem to some as hardly worth mentioning; but if the time lost due to carbide lamps was figured up on the five loading machines, I believe it would be found to amount

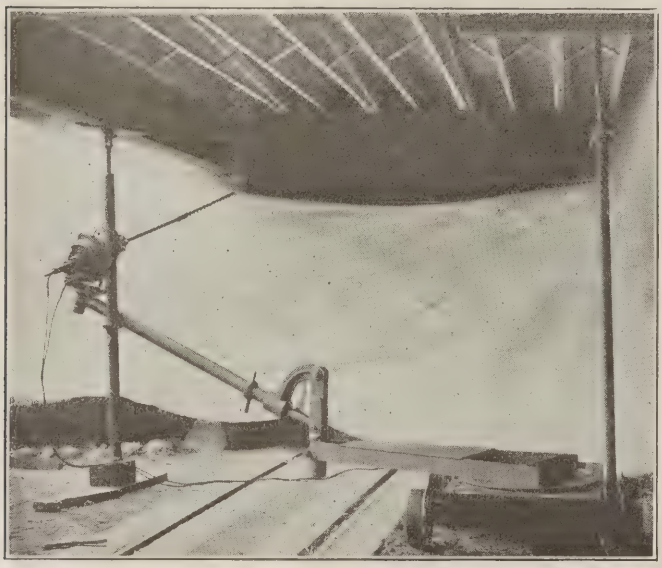

FIG. 6. SHOWING MANNER IN WHICH DRILL IS ADJUSTED FROM TRUCK

to considerable. It would, I believe, be a good idea to put in electric lights so that the men could work without their carbide lamps. There is power in the room already. Wire should be extended in the rooms from time to time so that it would not be necessary to unreel a cable and hook on in the entry three times a day, as in each day three kinds of machines are used in each room —that is, the undercutting machine, drill and loader.

Each of these ten rooms is loaded out once a shift. A 7-ft. cut in the size of room assumed will give 34 tons, or about 340 tons per shift from the ten rooms. This, it will be realized, is a good output from a small territory, and should mean a great saving in material, ventilation and upkeep of the mine.

As to the cost of the coal, this would have to be figured up for each mine, taking the conditions and labor scale into consideration. As to the number of laborers, there would be required 10 men for loading, 2 men for the shortwall machine, 1 or 2 men for the gathering locomotive and 1 man for drilling. This latter can also help lay track and assist with the timbering. In the same room with the man drilling another will probably be needed for taking up bottom and getting the room in proper shape.

Output per Underground Employee in British Coal Mines Decreases

The shortage of fuel is seriously felt throughout Great Britain, due in large part to scarcity of labor, great numbers of men having been withdrawn from mining operations during the last four years. But there is another factor of equal importance and of even greater significance which influences this matter, and that is the continual decline in output per person employed. According to R. W. Corless, in an address to the Past and Present Mining Students' Association, Wigan, and District Mining and Technical College, on Nov. 16, 1918, it does not seem that enough has been done to improve the individual output.

The accompanying table gives the returns for the years 1907 and 1917, from which comparisons may be made; the figures are arranged to show the output in tons per annum per person employed underground without taking any account of surface employees. Taking the average output, the loss of output per person in the 10 years is 47.2 tons; the number of persons employed

	Year, 1907			Year, 1917		
Section	No. of Persons Underground	Output	Output per Head	No. of Persons Underground	Output	Output per Head
Scotland.....	101,766	40,092,548	394	102,205	34,245,744	335
Northern.....	161,038	56,243,456	355	152,068	43,228,230	284
York and North Midland.....	.....	.....	.....	192,040	69,128,836	360
Lancashire and North Wales..	87,371	30,034,598	344	89,512	25,204,560	282
South Wales....	121,351	36,782,508	303	184,633	48,507,902	263
Midland and Southern.....	.....	.....	.....	90,397	28,062,201	310
	471,526	163,153,110	353.4 Average	810,855	248,377,473	306.2 Average

underground in the year 1917 is 811,510, and multiplying the total number of employees by 47.2 (the loss of output) we obtain 38,303,272 tons, or the total amount of coal lost through decreased individual tonnage.

The question—How are these figures going to be improved—has arisen. In recent years machinery has been brought more and more into use, particularly in undercutting the coal and in conveying the coal along the face, but Mr. Corless considers that they still lag a long way behind. Cases are continually met where output is sacrificed for want of power to replace manual labor. The hard seam of coal is still being undercut by hand, rock tunnels are still being driven by hand work, and the need of an auxiliary haulage system is felt to keep pace with advancing roads and to dispense with such old relics as crabs and similar devices.

Mr. Corless states there is not much doubt that, next to the actual cost of mining, the cost of transporting the coal from the face to the haulage road is one of the most expensive items in underground work; and this is perhaps one of the most laborious kinds of mining work, especially in those collieries where the gradient is fairly steep or the haulage roads are too few.

Following an explosion at a mine an experienced mechanic should at all times during the recovery work be stationed at the fan, prepared to make any necessary repairs following a breakdown. A messenger familiar with the plan of the mine should be constantly on duty to carry word into the mine in case the fan stops. If a telephone line has been installed, a man should be on duty constantly at each telephone.

Cleveland Coal Situation in 1918

By EDWIN C. BOEHRINGER
Cleveland, Ohio

SYNOPSIS — *Though supply of bituminous was never plentiful in the early part of the year, no essential war plants lost any time. Demand continued strong until Nov. 11, when the armistice was signed. Anthracite practically disappeared from the market, due to the operation of the zoning system. Pooling of coal through the Ore and Coal Exchange proved an unqualified success, and the likelihood is that the plan will be adhered to in a modified form. Opinions differ as to the outlook for the new year.*

WERE 1918 to be charted from a coal standpoint, demand would show an almost unbroken line across the 10½ months to Nov. 15, with a sharp decline downward from then to Dec. 31. Prices would show a slight decline from Jan. 1 to Apr. 1, a decided drop on that date, and remain on much the same level the remainder of the year, with a possible faint falling off from Nov. 15 to Dec. 31. Thus are revealed the principal trends of the bituminous year in Cleveland and northern Ohio.

The early months of the year strained the trade to the utmost. An unusually cold January and February, which called for greatly increased consumption, by the same token laid a heavy hand upon the railroads and cut down the supply in much the same proportion that demand rose. This situation was further complicated by the unusual requirements of the iron and steel, metal-working and rubber industries of Cleveland and northern Ohio—then very largely engaged in war work.

Doubtless the apprehension felt was heightened by the comparison of receipts then with former years. Steam-coal traveled the direct route from car to fireroom. Domestic coal was delivered in 100-lb. and 200-lb. lots instead of by the ton. But when the winter's hold was broken, it was found that no essential war plant had lost one minute's time through shortage of coal, nor did one home actually lack an immediate supply for one day. The margin, while dangerously narrow, sufficed at all times, and in fact some No. 8 coal was being dumped into Great Lakes freighters at Cleveland in March.

The winter over, efforts of the trade were concentrated on getting to the Northwest its allotment of 28,000,000 tons of bituminous. All summer long every ton of bituminous, including that from stripping and exceedingly low-grade operations, was quickly absorbed. Pressure from the United States Fuel Administration on both steam-coal and domestic consumers was applied, and not only did the Northwest get its 28,000,000 tons and more, but the entire lower lakes region was amply coaled when winter again broke.

Until Nov. 1 domestic demand continued unabated, and while new business was comparatively small, deferred orders were yet to be cared for. Retail dealers, in effect, did a winter business all summer. The unusually mild weather through October, November and December knocked the bottom entirely out of the domestic market and easily offset the more prosperous summer business. With the signing of the armistice Nov. 11, steam-coal demand fell as though it had been cut off with an ax. War work did not let up immediately, but industrials bent every effort toward depleting their war-priced, abnormal stock piles. The end of November saw overproduction just in the offing, and the first half of December found the market utterly stagnant. This was the condition when 1918 passed away, and demands for both domestic and steam coals were on rock bottom.

The beginning of 1918 saw bituminous still being delivered at contract prices. The Government maximums, strictly speaking, had little real effect here until Apr. 1, when prices dropped probably 65c. a ton on the average. Until the middle of November bituminous prices held firm at the Government maximums. Then, with standard No. 8 available, stripping coal softened, and soon was being offered at as much as 70c. off. Some stripping coal in middle December went at 90c. off. On the theory that reduced prices would not stimulate demand, the larger No. 8 operators held firm for the Government maximums. Some regular No. 8 coal was disposed of in December at about 25c. off the maximums—which for Ohio generally were $2.35 for mine run, and $2.60 for slack and prepared sizes. Domestic grades in December were bringing, delivered, $7.10 for Massillon lump, $6.60 for Coshocton, $6.35 for No. 8 Pittsburgh and $6.15 for West Virginia splint. These prices were from 50 to 75c. under the prices that ruled in the summer. The quality of domestic coal was quite poor throughout the year, and not until November were buyers given 1¼-in. lump instead of ¾-inch.

As a market factor, anthracite virtually disappeared. Operation of the zoning system kept out throughout the year about 75 per cent. of the normal supply. In December anthracite was bringing $10.35 in Cleveland, about $1 a ton higher than in the spring. Coke was pushed as a substitute, at from $11.50 to $14 a ton. It proved a poor, high-priced substitute, and the re-

COMPARATIVE MOVEMENT OF BITUMINOUS AND ANTHRACITE COAL ON GREAT LAKES

*Includes total of 22,193 tons dumped prior to beginning of season and operation of Ore and Coal Exchange.

turn of anthracite and Pocahontas will probably push it almost entirely out of the domestic market.

Pooling of cargo and coal tonnages through the Ore and Coal Exchange of Cleveland made the lake season an unqualified success. Though only August, October and November equaled or exceeded the monthly quota set by the Fuel Administration, the Northwest was given 28,153,317 tons of bituminous, while Lake Erie car dumpers handled an additional 1,234,925 tons in the way of fuel coal. The season's grand total thus was 29,388,242 tons of bituminous. The cargo coal accorded the Northwest in 1917 was 26,828,957 tons, or 1,324,360 tons less than this year. Of the 1918 tonnage the three docks at Toledo handled 10,338,757 tons—combining cargo and fuel coal—Ashtabula's two docks 3,699,048, Cleveland's two 3,533,513, and Lorain's one 3,434,994 tons.

Bituminous Trade Pessimistic At Present

At present the bituminous trade is most pessimistic. With steam coal demand away off, domestic users still stocked and the lake season over, all of the elements loom up unfavorably. The bright spots in the way of nibbling by several large steam-coal users who have pretty well eaten into their stock piles are eclipsed by the general pessimism. This depression, it is believed, will largely be dissipated by the opening of the lake season, which is only 60 days in the future. Their backs put to the wall, the larger and better-informed operators appear 100 percenters—either very optimistic or very pessimistic. There appears to be mighty little middle ground.

One view, which is not widely shared, is that bituminous will fall into the same slough as after the 1902 anthracite strike, and that with war demand for fuel over, the market has changed from a seller's to a buyer's; that it will take the industry fully ten years to recover from its present state of overproduction. This view includes a crash not later than the early spring months, with No. 8 mine-run as low as $1.50 before the upturn.

The other view, more generally held, is that the industry will encounter nothing but boom times in 1919, beginning in late February or early March. The country, these operators believe, will rush through its readjustment; export demand will be big; with the discarding of zone restrictions, No. 8 coal will find its welcome as warm as ever in Michigan; next November and December can be no worse than those months this year, from the standpoint of domestic consumption; and that the Northwest usually takes from 27,000,000 to 28,000,000 tons.

Negotiations for a new bituminous wage scale are held certain to come some time in 1919, and the belief is universal that this will result in shutdowns at the mines for 30 to 45 days at a minimum. Ten per cent. of the year's production, accordingly, will be lost this way, and from this prices will not suffer in the least. With ratification of the peace treaty and consequent opening of the wage scale before April seemingly improbable, operators expect to begin floating lake coal again at $2.80. This, too, is expected to be a factor in maintaining present prices. Many operators advance the theory that the experience of large steam-coal users in stocking with low-grade and stripping coal, and their losses through fires, will serve to bring quality into the forefront at the expense of price. It is agreed on all sides that, in any event, prices cannot go down until labor does. If the wage negotiations are begun before living costs have receded, the mine workers will succeed to another year of high wages, with prices accordingly.

Forecast of Conditions for 1919

The forecast is for a late start in the lake trade next spring, for a large part of the Great Lakes fleet is wintering at Buffalo with storage grain cargoes. About two weeks will be clipped off the start, for navigation opens at Buffalo usually a fortnight or so later than at Toledo and Cleveland. The pool is likely to be continued, though in a modified form. It is certain that the 1919 pool, if any, will not permit the mixing of coal on upper lake docks such as resulted in 1918. Losses through fires have been too severe to leave this detail unnoticed. From 27,000,000 to 28,000,000 tons again will be taken up, with the former figure nearer correct. Dock piles on the upper lakes seem certain to be much larger in the spring than they were last spring.

The lake and domestic trade sizing up as normal or virtually so for 1919, the great uncertainty lies in the steam-coal situation, and this, naturally, will be no better or no worse than general business conditions. The worst, for the local trade, seems likely to be over by the middle of March. Prices only slightly lower than in 1918, with demand 85 to 90 per cent. of what it averaged through 1918, is the by and large of the trade's views here.

Coke Industry in 1918

By WARREN S. BLAUVELT
Detroit, Michigan

THE story of the coke industry in 1918 is an interesting chapter in the history of the Great War. It is a story of the rapid development of the spirit of patriotic coöperation of coke manufacturers, coke workers, railroad men and coke consumers with the War Industries Board and Fuel Administration. With this spirit actuating the industry and those connected therewith, difficulties which appeared insurmountable were largely overcome, and the coke industry was enabled to do its part in winning the war.

Production of coke was curtailed in January, February and March over 2,000,000 tons by weather conditions which prevented regular movement of coke from beehive ovens to furnaces, and of coal to byproduct ovens. The quick improvement in railroad conditions with the advent of milder weather was made possible only by the strenuous and effective work of all the men in the railroad service.

As production increased in May, June and July stocks of coke were accumulated at furnaces remote from the coke districts. Unfortunately, the extremely hot weather early in August again curtailed the output about 100,000 tons. Fortunately for the war program, the stocks previously accumulated made it possible to keep nearly all furnaces in blast during this period. In October and November, coke production was reduced about 350,000 tons by the influenza epidemic.

In the Connellsville region in West Virginia, Virginia, Kentucky and Tennessee there was an actual shortage of labor the greater part of the year. In Alabama there were apparently enough men to man the coke plants, but chronic absenteeism, and the habit of frequently moving from place to place, reduced the available coke labor far below war requirements. Unfortunately, the campaign to correct this difficulty was not started in Alabama till the latter part of the summer and was seriously hampered by the epidemic, which was general in the district. But notwithstanding the difficulties due to the weather, the influenza and the shortage of labor, the production of metallurgical coke in 1918 was about 1,000,000 tons greater than in 1917.

The new byproduct ovens which were started in 1918 made this increase possible. In the latter part of October, for the first time in this country, more byproduct than beehive coke was being produced. The productive capacity of the byproduct ovens in the United States has been increased about 36 per cent. during the year.

The activities of the Fuel Administration in connection with the coke industry were along the following lines: (1) Establishment of maximum prices. (2) Efforts to increase production. (3) Control of distribution. (4) Efforts to improve quality.

The basis of all price-fixing orders was the price recommended to the President by the committees of the American Iron and Steel Institute and the War Industries Board, and approved by him on Sept. 24, 1917. In general, the policy of the Fuel Administration in fixing prices was to establish maximum prices as low as practicable and yet secure the production required.

A price of $1 per ton more for foundry than for furnace coke was allowed on Nov. 10, 1917. This made the price ratio between furnace and foundry coke about the same as before the war. It also had the effect of making it possible for foundries engaged in war work to secure their coke generally without Government assistance, and this relieved the Fuel Administration of a vast amount of work which otherwise would have been necessary. This greatly expedited the production of castings needed in the war industries, as there were few delays from failure to secure foundry coke.

Prices for byproduct coke were allowed which permitted the absorption of freight differentials, thus leaving the price relation between beehive and byproduct coke essentially the same as before the war. Disregarding these two price differentials, the orders affecting prices permitted advances above the base price originally established, on a merchant tonnage of only about 4,250,000 tons of coke per year, or about 7½ per cent. of the total year's production of coke.

Efforts to secure an increased production were made: (1) With the Railroad Administration, to secure a regular and adequate car supply for the movement of coke and byproduct coal. (2) With operators, to secure their maximum effort to increase output. (3) With employees, to get them to work steadily. (4) With the Employment Service Bureau and with draft boards, to increase the available labor at coke plants. (5) To secure physicians and nurses where needed on account of the epidemic of influenza. (6) With the general public in the coke regions, to establish an effective public opinion, honoring those who worked faithfully to secure the coke needed for war purposes, and shaming the slackers.

In the control of distribution the Fuel Administration was the organization for making effective the requests of the War Industries Board for the movement of coke. The general coöperation of the coke industry with the War Industries Board and the Fuel Administration is evidenced by the fact that in no one month was it necessary to issue orders or requests to coke producers for the movement of a tonnage of coke exceeding 1¼ per cent. of the total production for the month.

The constantly increasing demands for coke, irregularity in car supply and the labor shortage in many fields resulted in much off-grade coke being produced and moved to furnaces. Upon this being brought to the attention of the Fuel Administration, coke inspectors were appointed to investigate complaints and remedy conditions where possible. In some cases prices were reduced where off-grade coke was being shipped.

In the work of the Fuel Administration the effort was made to utilize the existing agencies of production and distribution, and to alter trade practices and methods only where such changes promised to mobilize the coke industry more effectively for the vigorous prosecution of the war.

Louisville Coal Trade in 1918

By A. W. WILLIAMS
Louisville, Ky.

SYNOPSIS — *Western Kentucky coal obtains a firm hold on Louisville market. Strong possibility that river trade will receive new impetus. Considerable development work throughout the state, particularly in the Elkhorn fields. Business during the new year depends largely on removal of Government restrictions.*

As a result of the zoning out of certain coals during the spring and summer season of 1918, when eastern Kentucky grades were shipped largely into Michigan, the Lake region and to gas and byproducts plants, western Kentucky coal got a better foothold on the Louisville market than at any previous time in its history. For several months western Kentucky coal came in well, and most of the summer stocking was done on this grade. A considerable amount of higher grade coal, known as Hazard coal, a slow-burning, white-ash coal produced in eastern Kentucky, also became much better known in the local market. This coal is really an excellent coal for domestic purposes and represented about the only grade of eastern Kentucky to be had on the market, as other eastern Kentucky coals were largely gas coals, which were needed for other purposes. Louisville and vicinity was largely stocked on western Kentucky domestic, however. Numerous steam consumers also purchased this coal to a greater extent than ever before.

It is believed that as a result of the heavy stocking and use of western Kentucky coal in Louisville during the past year, that it will have a much better sale here in the future, owing in part to the fact that it sells at a lower price than some of the higher grade eastern Kentucky varieties.

Louisville Able to Procure Usual Grades

Except for a few months when eastern Kentucky coal was routed to the north, Louisville was able to secure her usual grades. Louisville depends almost entirely on Kentucky production, consuming Hazard coal, western Kentucky, Harlan, Straight Creek, Jellico, Elkhorn and some little Glue Gem. The latter does not come into Louisville to any such extent as Hazard or Harlan. In addition there is some little Indiana coal, which comes in by rail to the western end of the city, over the Kentucky & Indiana Terminal. However, Indiana coal has never been used to any considerable extent here.

In addition to these Kentucky coals there was formerly a considerable tonnage of West Virginia coal, and other coal from the Pittsburgh field district. Years ago most of the coal consumed in the Ohio Valley towns came from the upper river fields by water. Later a considerable volume was handled by rail. When the war broke out the high-grade eastern coals went into the east and Pittsburgh district, where they commanded a ready market.

The demand in those districts today is not so keen as it was, and there is a strong possibility that the Monongahela company and other large river coal shippers will get back into the river game again. It is claimed that inquiries are being made all along the river for boats, barges and tow boats for river transportation of coal, and that boat builders have been asked for quotations. There is likely to be a return of the heavy movement of coal by water from the old upper Ohio and Kanawha River districts clean to the gulf. This would naturally cut in on the rail shippers materially, as rail rates are showing a 25 per cent. increase, whereas there has been no increase in water rates other than the actual increase in the cost of transportation, which in many cases is done by the jobber or producer.

Increase of River Traffic During Year

During the past year there has been somewhat of an increase in river transportation of coal by small Kentucky companies, and some large ones. The West Kentucky Coal Co., Sturgis, Ky., is interesting itself to a considerable degree in river shipping, and is collecting a fleet. The Beattyville Coal Co., on the Kentucky River, is also getting into waterway transportation, which is much cheaper if ice and other hazards do not wreck the equipment.

Kentucky production has increased greatly since the war started, due to a ready and eager demand for coal of all qualities, sizes and grades. Considerable activity has been seen in the western Kentucky field, where many new mines have been opened. The Hazard district has seen many new operations started. The Cumberland & Manchester R.R. opened up large fields in the eastern section of the state, and some big developments are promised in that region. In the Harlan districts several companies are waiting on railroad extensions and plan development when it is possible to reach market. In the Elkhorn fields, around the extreme eastern section of the coal fields of the state, a greater amount of development has been reported than from any other section. Several branch railroads are going into that district, and many new mining towns, with power-equipped mining companies, are getting ready to ship coal as soon as the lines are completed. Numerous other developments have been reported from the Harlan and Hazard fields, also from around the Straight Creek and Jellico fields.

At the present time there is little demand for coal of any grade, and mines are generally working on reduced time. The producers and jobbers are making a hard drive for business, but steam consumers are still loaded up and are operating on a smaller consumption basis themselves. Domestic consumers are well stocked, and due to the mild weather their stocks may carry them much later into the spring than had been anticipated. It had been generally believed that stocks would carry the domestic consumer until about Feb. 1, but unless cold weather is experienced

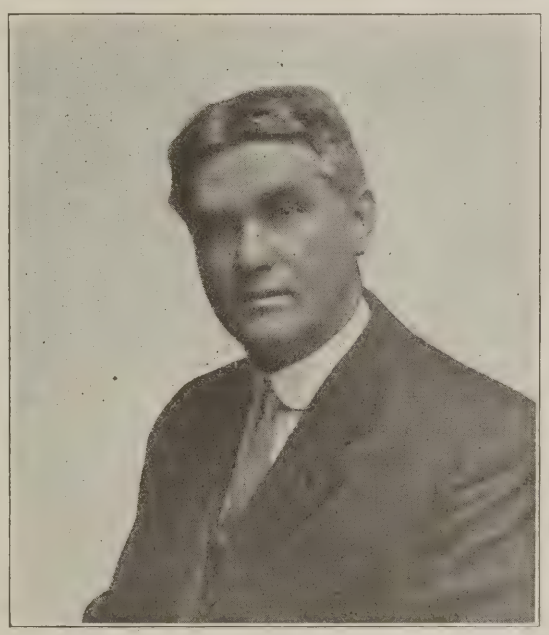
in the month of January many domestic consumers will run the season out on less than two-thirds of the coal they burned last year, and without exhausting their stocks, which in many cases were based largely on last year's consumption.

Retailers have no business to speak of. Their trucks and wagons have been put up, about one-third of their delivery equipment being kept busy. Many laid in large yard stocks of mine-run and low-grade coals, fearing a repetition of the troubles of 1917, and figuring that it would be far better to have coal of any description on hand than to be delivering direct from cars, as was the case in 1917. Prices have been weaker on all grades, and retailers have been trying to reduce stocks on hand rather than buy any additional coal, as it appears certain that prices will go no higher and high-priced low grades now on hand must be cleaned up.

Fixed Prices Stabilized Market

As a result of Government prices the market has held up in good shape. Retailers, jobbers and producers in many instances have been guilty of cutting prices slightly in order to create business. However, with a maximum Government price to work from, there has been some sort of an established market, with the result that few operators have cut more than 50c. a ton from the Government maximum prices. This has afforded the retailer a little more security than in former years. It is now a question as to when all prices and restrictions will be taken off. Restrictions have been removed in the flour-milling and other industries, and are likely to be removed from coal at any time. Many coal men adhere to the belief that in the event Government prices are relinquished the coal trade should continue to operate as close to these prices as possible and take advantage of the fact that the Government set aside the Sherman act in creating maximum prices. Such action would not represent any combine in restraint of trade, but it appears as though it will be utterly impossible to hold the trade in line.

The retailers have done better during the past two years than at any previous time in their history. Credits have been extended for only thirty to sixty days at the most, while many of the sales have been made on a cash basis. However, today retailers are so anxious to sell that they are not so particular as they were regarding cash or credit, and it is likely that conditions will eventually return to their former stage, when many consumers only paid their bills when they wanted to restock.



The prospects for the new year are uncertain. Rail producers cannot get away from the belief that river transportation will again be a serious factor. The zone system has lost many former connections for producers in certain sections, with the result that much rebuilding will have to be done, and at a considerable cost. Many producers have been putting their profits right back into mine improvements and additional mines, with the result that they are now tied up with the banks, and in many cases are poorer than they were insofar as ready cash is concerned. However, they have better facilities for getting out coal than they had before, and more valuable properties. They have lost far less on credits than at any previous time in their history. What the year will bring forth is any man's guess, but with the elimination of the zoning system it is believed that business as a whole will return to about the same general plane that it was on before the war.

James Scott Thompson Dies

In the death of James Scott Thompson at Salt Lake on Jan. 15 the coal industry of America loses one of its most forceful and efficient mining men of the younger generation. Mr. Thompson's death was unexpected and came as a result of heart disease.

He was born in Chicago in 1875 and graduated from the Colorado School of Mines in 1899. Physically, few men were more powerful than Mr. Thompson. During his college course he gained a wide reputation in western athletics, being recognized as one of the greatest football stars in the Rocky Mountain country.

Practically all of his business life was spent in the service of coal corporations. On leaving the School of

JAMES SCOTT THOMPSON

Mines he was first employed by the Colorado Fuel and Iron Co. Later he became assistant superintendent for the Federal Lead Co. in Missouri, but in less than a year returned to the coal fields, accepting a position as general superintendent of the Stone Canyon Consolidated Coal Co. in California. In 1909 he again entered the employ of the Colorado Fuel and Iron Co., continuing in its service until 1914, when he was appointed general superintendent of the Utah Fuel Co., which position he continued to hold until the time of his death.

Mr. Thompson is a member of the American Mining Congress and the Rocky Mountain Coal Mining Institute. His sudden death has come as a sharp blow to his host of friends throughout the country. The coal industries of Colorado and Utah, however, will continue to feel the influence and benefit of his effective service for a long time to come.

Preparation of No. 4 Buckwheat in the Cone Separator

SYNOPSIS — *With the increasing demand for and cost of anthracite, greater refinements in preparation and conservation of this valuable fuel are necessary. Among the methods used for cleaning the smaller buckwheats is the cone separator—a device long used in removing impurities from bituminous coal. Its adaptation to anthracite requirements, modifications in design and some of the results obtained, are described in this account of an interesting experiment being tried by the Lehigh Coal and Navigation Company.*

PENNSYLVANIA anthracite was likely the first coal to be washed in the United States. And probably the first extensive washing of anthracite was undertaken by the Lehigh Coal and Navigation Co. about the year 1875. This company has jigged domestic coal for many years, separating it from slate by this and other well-known methods. Until recently No. 1 buckwheat was the smallest size of anthracite cleaned of impurities. Now the Lehigh Coal and Navigation Co. improves its No. 4 buckwheat to such an extent that instead of its carrying 30 to 35 per cent. ash of ordinary breaker preparation, this size contains only 17 to 18 per cent. ash, in everyday practice; it has been cleaned down to 11 to 12 per cent. ash.

The company in question is accomplishing this result by a cone separator (shown in the accompanying illustrations), and the method is attracting much attention among anthracite operators. Bituminous coal has been cleaned by the Robinson and Howe machines for some time, but it is believed that this is the first application of these processes to anthracite preparation. The Lehigh Coal and Navigation Co. began experimenting with this separator early in 1916, adapting it to the requirements of anthracite. During this time the size and shape of the cone was changed somewhat; at present it is constructed as shown in detail in Fig. 1, and its relation to accessory parts is given in the section of that portion of a breaker equipped with this device (Fig. 2).

In the breakers equipped with the cone separator all slush water from the jigs and shakers goes to the collecting tank *A* (Fig. 2). From this tank the slush water is pumped by a 3000-gal. centrifugal pump through a 10-in. pipe to the cone separator. The pipe from the pump to the cone should be as short and have as few turns as possible, to avoid clogging up. The tank is always higher than the pump, to avoid having to prime the latter. The slush water enters the cone separator near the bottom and overflows around the circumference of the top. Entering the cone through a 10-in. pipe, the water rises and spreads out to fill a cone with a top ring measuring 7 ft. 8 in. in diameter. Thus the velocity of the water, carrying the fine coal, slate and other impurities, is considerably reduced; the slate and heavy impurities settle to the bottom and the lighter coal rises and goes over the top with the water.

A vertical shaft in the center of the cone carries three sets of horizontal arms; this stirring apparatus revolves at the rate of 12 r.p.m., keeps the contents of the cone agitated and does not permit fine material to settle on the sides of the cone. In Fig. 1 the extension of the bottom of the cone is omitted; it is shown in Fig. 2 and is marked *E*. The portion *E* is a metal cylinder equipped with two slide gates. As the slate and other refuse accumulates at the bottom of the cone, it is removed by opening these slide gates, one at a time. Thus this bottom contrivance acts as a lock and the cone water is retained while the impurities are being removed.

The top of the cone separator is surrounded by a trough by means of which the water overflowing from the cone is carried to a series of dewatering chutes *G*. These chutes have a pitch of about one in twelve and dewater the fine coal carried out of the cone with

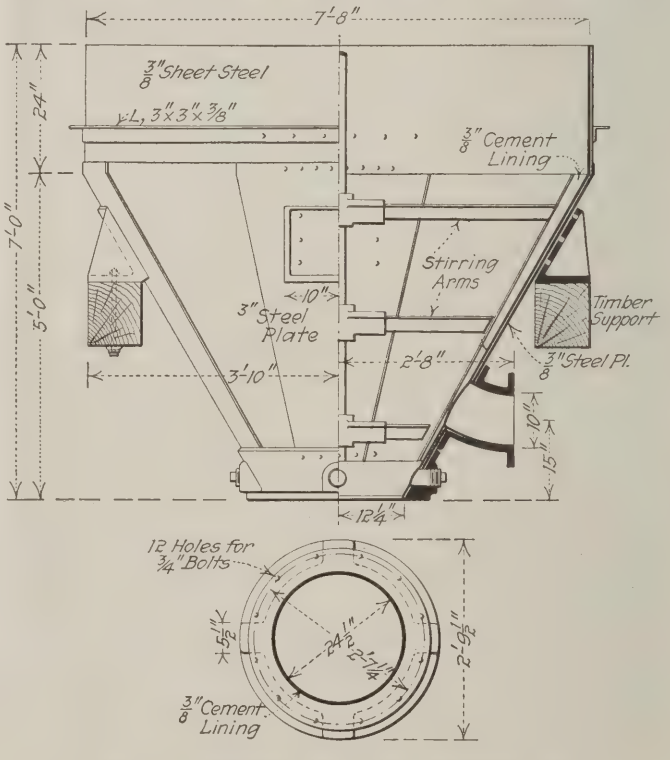


FIG. 1. DETAILS OF CONE SEPARATOR

the water. These chutes consist of a screen with $\frac{3}{16}$-in. perforations under which is a trough; water coming through the screens is collected by the troughs, from which the water is led away by the vertical boxes *H*.

Coal passing over the dewatering chutes goes to the shaking screen *J* where the dewatering process is completed. This shaker is necessary not only to carry the coal to a point where the material is entirely dewatered, but it is also useful to transport the coal to the storage

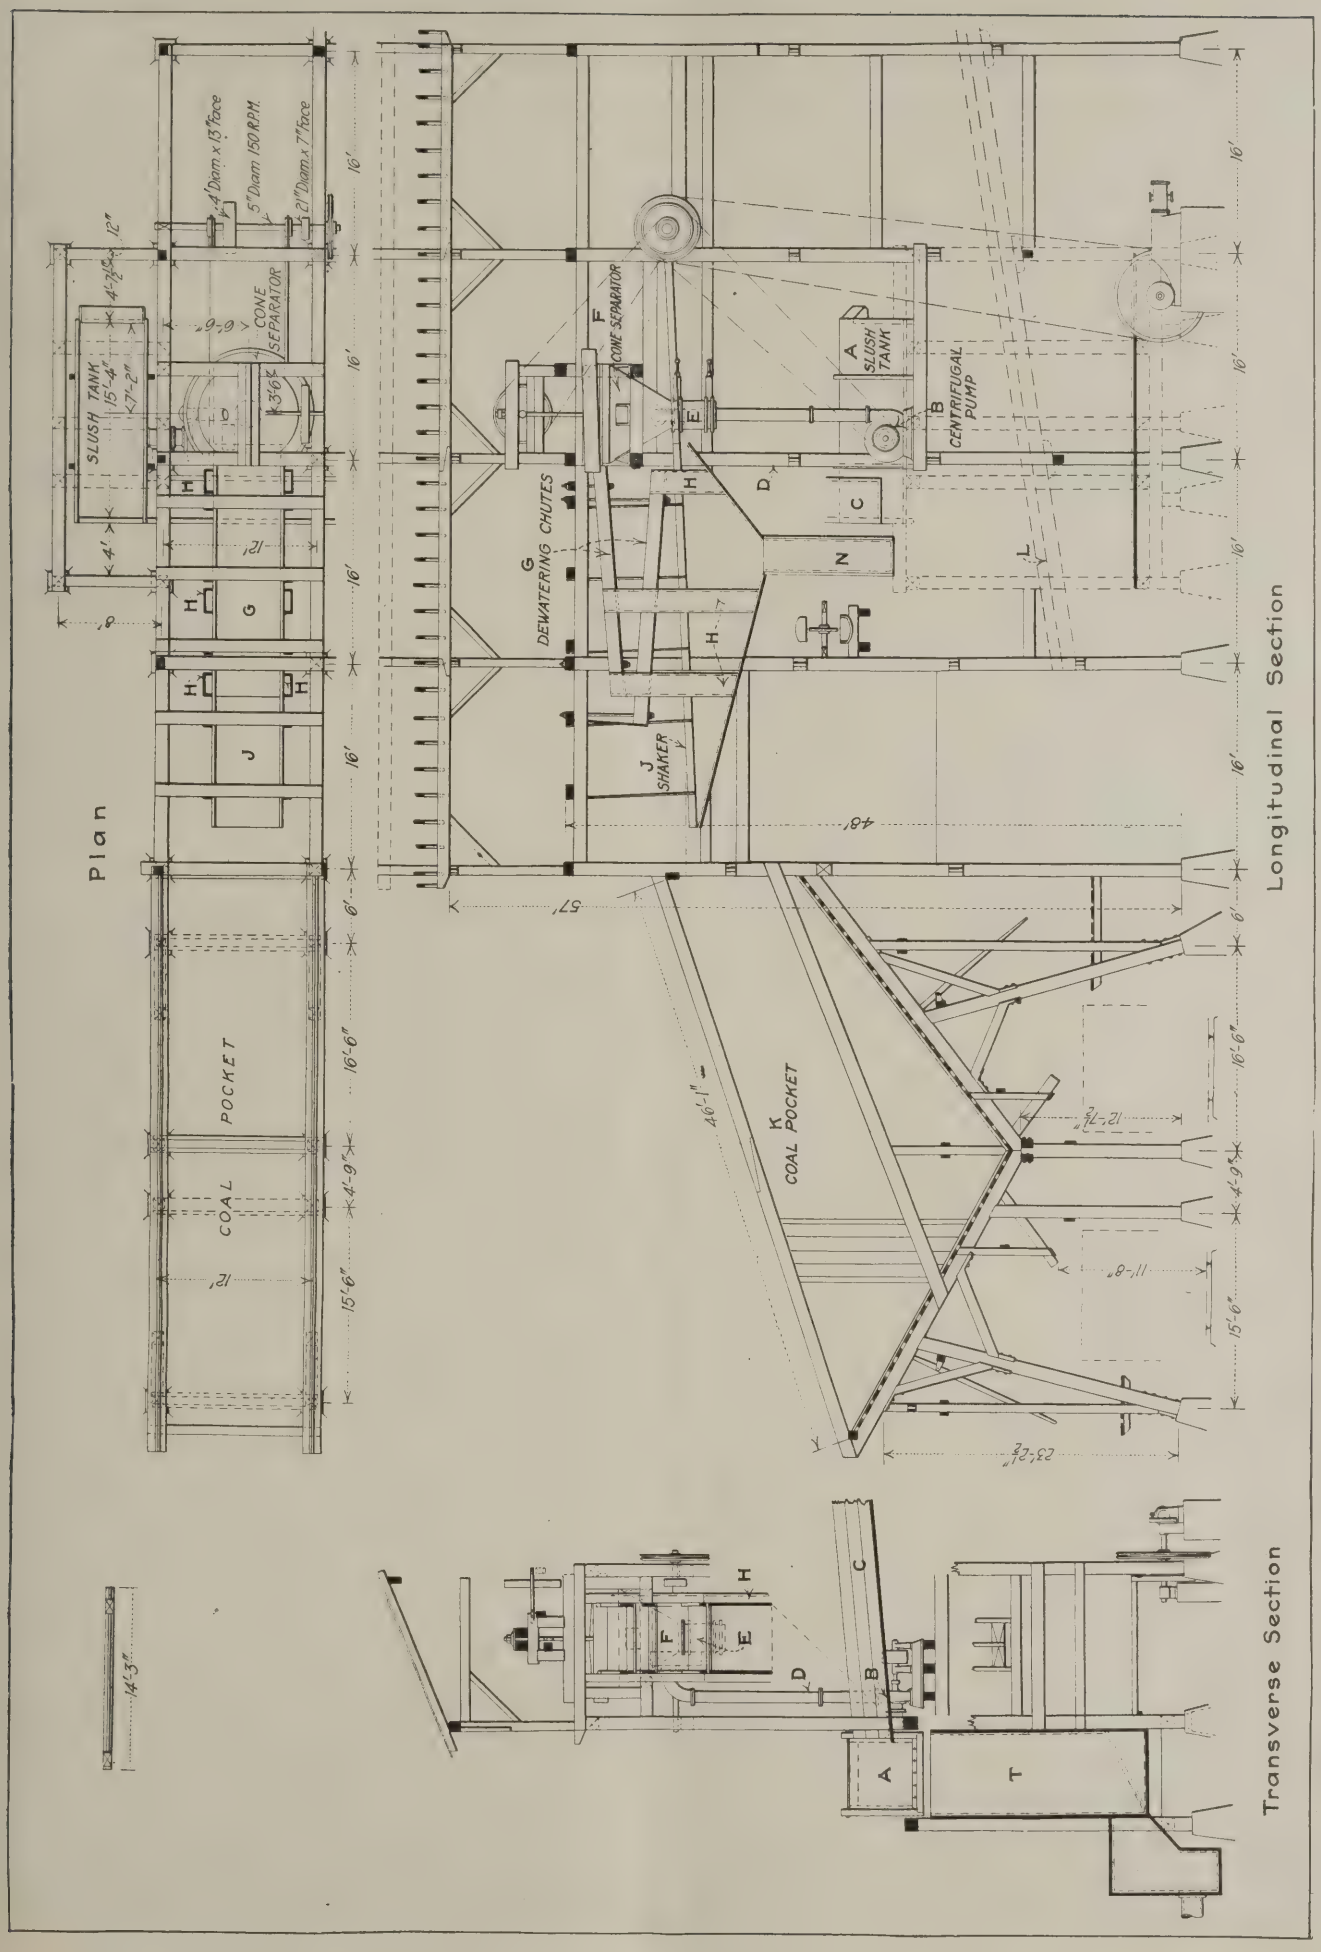

FIG. 2. INSTALLATION OF CONE SEPARATOR AND ACCESSORY PARTS IN A BREAKER OF THE LEHIGH COAL AND NAVIGATION COMPANY

pocket from which railroad cars are loaded. The shaker runs at the rate of 150 r.p.m. All water from the dewatering chutes and the shaker is collected in a hopper under the shaker; from here it is carried by a chute to the tank *T*, from which it is pumped to dams.

Special provision is made to load No. 4 buckwheat into railroad cars, as it takes longer to load it than other coal. It is loaded on tracks other than the main loading tracks for this reason. Two loading tracks are shown under the No. 4 buckwheat pocket in Fig. 2.

The Lehigh Coal and Navigation Co. has five cone separator installations at the following plants: The Nesquehoning, Lansford, Tamaqua and Coaldale breakers, and the Ashton washery. Sand, gravel and slate are removed from No. 4 buckwheat in the cone separator and coal dirt and mud in the dewatering apparatus. Each cone separator has a capacity of 150 to 250 tons per day. The total production of No. 4 buckwheat (by this process) at these five Lehigh Coal and Navigation Co. plants for the months of March to November inclusive of the year 1918 was 14,142, 12,934, 14,333, 12,025, 6818, 17,485, 12,035, 17,367 and 16,007 tons respectively. This tonnage was from freshly mined and washery coal and amounted to 123,146 tons for the nine months noted. This company can dispose of all of the No. 4 buckwheat it can produce which does not contain more than 17 to 18 per cent. of ash; the amount of refuse remaining in this size of coal after treatment by the new method is well within this limit. The Lehigh Coal and Navigation Co. uses No. 4 buckwheat with low amounts of impurities in its briquet plant and sells it as fuel, thus conserving valuable coal.

The cone separator should be serviceable in removing gravel from the small sizes of coal from strippings. Gravel frequently is washed into strippings from adjoining banks, gets mixed with the coal and generally is a nuisance in preparation. Sulphur is another impurity which it is highly desirable to remove from prepared coal. Probably certain forms of sulphur are more commonly found in the smaller sizes than in any other size of anthracite, often occurring in the form of scales. In the smaller sizes these scales generally become detached from the particles of coal and their removal should be readily effected in the cone separator.

Furthermore, in large lumps, good coal is often found attached to slate and rock. By crushing and recrushing a more or less complete separation is possible and the resulting material is in ideal shape for treatment by the cone process. There seems to be a difference of opinion as to the possibilities of this method of cleaning anthracite. But there is a tendency on the part of some of the officials of the Lehigh Coal and Navigation Co. to further investigate the matter, believing its scope is wider than its present use.

Nearly 600,000 more cars of coal were loaded during 1918 than was the case in 1917, according to figures compiled by the Railroad Administration. The loadings during the week ended Dec. 28, as compared with those of the corresponding week of 1917, are as follows:

	1918	1917
Total cars bituminous	107,350	154,883
Total cars anthracite	24,564	28,992
Total cars lignite	3,490	4,550
Grand total all cars coal	135,404	138,425

Pooling Report of the Wholesale Coal Trade Association

A conference to consider recommendations and suggestions contained in a report on matters concerning the Tidewater Coal Exchange made by the Bituminous Operators' Committee of the Wholesale Coal Trade Association of New York, of which W. A. Marshall is the chairman, was held on Jan. 15 in the New York office of the Exchange. Those in attendance were J. W. Howe, Commissioner of the Tidewater Coal Exchange; George F. Malone, Deputy Commissioner, at Baltimore; Mr. Bailey, of Norfolk; J. W. Searles, Deputy Commissioner, and his assistant, Mr. Thompson, of the New York office of the Exchange; Mr. Marshall, John W. Whitely, Charles A. Owen and Charles S. Allen, representing the Wholesale Coal Trade Association.

Mr. Marshall, in the committee's report, named three respects in which the present rules governing the Exchange should be amended. They are: (1) A more scientific classification; (2) a different method of apportioning demurrage charges and (3) a change in the method of placing embargoes.

The committee believes that with the present demurrage rules and charges it is highly important that the Exchange should be continued, and that it is certain that without the pools, the demurrage charges would be so heavy as to make it impossible for many, if not all, to ship to tide.

Present Classification of Coal Unscientific

The present classification is on so unscientific a basis, says the report, that it works a grave hardship upon the shippers of high-grade coal to a given pool, much trouble having been experienced due to the fact that inferior coals have been shipped to pools supposed to have only coals of better grades, and when sold on the latter basis have proved unsatisfactory upon delivery, resulting in complaints and in some cases loss to the shipper. Many consumers by way of protest against this unscientific classification are now demanding that their coal, whenever possible, be sent to them all-rail so as to avoid this difficulty; and this is being done even in the face of extra transportation and handling charges.

It was decided at the conference that a committee or committees will be appointed by the Executive Committee of the Tidewater Coal Exchange, probably at its next meeting, to take up and handle to a prompt conclusion this matter.

The conference then took up the matter of demurrage charges. On this matter the report states that demurrage charges should be assessed against and paid only by those shippers on whose shipments the charges have accrued and in proportion to the amount accrued against each individual; that those shippers should have the benefit of the credits earned, if any, by those handling their shipments within the free time, but that those so handling their coal should not be made to bear any part of the demurrage charges caused by others. In other words, that the credits made, if any, should go to reduce the charges against the less fortunate members of the pool, but that they and they alone should bear the penalty for lack of promptness in disposing of the coal handled for their account.

It was announced at the conference that this recommendation had been adopted by the Exchange and that it would be put into effect as soon as the necessary details were worked out.

The report stated that the present rules of the Exchange provide that when a shipper fails to furnish boats to promptly move his consignments, an embargo shall be placed against further shipments by that person. This, the committee believes, should be done in all cases; but the embargo should not be applied to every shipper through a given pool, regardless of his performance in moving his consignments.

The Exchange, it was announced following the conference, commended this recommendation, and the matter is now being handled by the Railroad Administration with a view to preventing the placing of embargoes except upon the recommendation of the Exchange. It was announced by Mr. Searles that the assent of all but one of the carriers had been obtained, though it was expected that this would be received in a short time. The committee of the association in its report suggested the following schedule for coal classification:

	Specifications	Description	Classification
1	Volatile under 24 Ash under 8.50 Sulphur under 1.50	Low volatile Low ash Low sulphur	Smithing
2	Volatile 24 to 32 Ash under 8.50 Sulphur under 1.50	Medium volatile Low ash Low sulphur	Byproduct and high grade gas coal
3	Volatile over 32 Ash under 8.50 Sulphur under 1.50	High volatile Low ash Low sulphur	Byproduct and high grade gas coal
4	Volatile under 24 Ash 8.50 to 12 Sulphur under 1.5	Low volatile Medium ash Low sulphur	Stoker non-clinkering
5	Volatile 24 to 32 Ash 8.50 to 12 Sulphur under 1.50	Medium volatile Medium ash Low sulphur	Stoker non-clinkering
6	Volatile over 32 Ash 8.50 to 12 Sulphur under 1.50	High volatile Medium ash Low sulphur	Railroad fuel
7	Volatile under 24 Ash under 8.50 Sulphur over 1.50	Low volatile Low ash High sulphur	High B.t.u.
8	Volatile 24 to 32 Ash under 8.50 Sulphur over 1.50	Medium volatile Low ash High sulphur	High B.t.u.
9	Volatile over 32 Ash under 8.50 Sulphur over 1.50	Low volatile Low ash High sulphur	Railroad fuel, cement plants, etc.
10	Volatile under 24 Ash 8.50 to 12 Sulphur over 1.50	Low volatile Medium ash High sulphur	Fair coal graded as to volatile
11	Volatile 24 to 32 Ash 8.50 to 12 Sulphur over 1.50	Medium volatile Medium ash High sulphur	Fair coal graded as to volatile
12	Volatile over 32 Ash 8.50 to 12 Sulphur over 1.50	High volatile Medium ash High sulphur	Fair coal graded as to volatile
13	Volatile under 24 Ash over 12 Sulphur over 1.50	Low volatile High ash High sulphur	Cheap fuel varying as to volatile or character as to smoke
14	Volatile 24 to 32 Ash over 12 Sulphur over 1.50	Medium volume High ash High sulphur	Cheap fuel varying as to volatile or character as to smoke
15	Volatile over 32 Ash over 12 Sulphur over 1.50	High volatile High ash High sulphur	Cheap fuel varying as to volatile or character as to smoke
	Rejected coals		
16	Volatile under 30 Croppy or badly prepared	Low volatile	
17	Volatile over 30 Croppy and badly prepared	High volatile	

The suggestion has been made that the use of the B.t.u. basis be substituted for the percentage of ash, and the fusing temperature be substituted for the percentage of sulphur.

New Type of Tire Expander for Use in Coal Mines

The accompanying illustration shows a new tire expander designed for coal mines and being produced by the Hauck Manufacturing Co., of Brooklyn, N. Y. It is claimed that it will expand steel in five minutes and heat to cherry red in seven minutes.

The expander consists of two special kerosene burners, a 12-gal. tank with hand pump, built inside the tank; two 12-ft. lengths of oil-resisting hose, and an adjustable sectional shield which is placed on the tire.

NEW TYPE OF TIRE HEATER FOR MINE USE

The latter is constructed in 10 in. sections and can be adjusted to fit any size tire.

Where no compressed air is available the tire heater is furnished with kerosene-vaporizing burners—which operate about three hours with one pumping. Where compressed air is available the tire heater is furnished with compressed-air burners, and it also can be furnished as a combination hand pump and compressed-air outfit. The burners when not used with the heater can be used for many special purposes where an intense heat is required, such as brazing, preheating for oxy-acetylene welding, loosening nuts, boiler repairing, straightening shafts, expanding machine parts, making shrink fits, melting out babbitt from bearings, general locomotive and car-repair work, thawing out railroad switches, thawing out empty coal cars for closing the hoppers, and for many other heating operations.

Consumers' and Dealers' Reports To Be Discontinued in Near Future

Weekly reports from industrial consumers and coal dealers, which have been required by the Fuel Administration since June, 1918, will be discontinued after Feb. 1. These reports, coming from nearly 70,000 sources, were used in determining the equitable distribution of coal. With the discontinuance of these reports, it is probable that the distribution section of the Fuel Administration will have only an advisory relation with the Fuel Administration.

Cincinnati Market Conditions in 1918

By KENNETH C. CRAIN
Cincinnati, Ohio

THE past year in Cincinnati was in many respects the most extraordinary which the coal trade has ever experienced, not only on account of the conditions common to the trade everywhere, but through some which were perhaps a trifle emphasized locally. The extremely severe winter which was experienced, with some of the worst weather in years during January and February, of course had its effect on the coal business, resulting in a heavy and continuous demand, which was filled locally only with considerable difficulty, and which in some instances in nearby towns could not be taken care of at all.

The year thus ushered in was destined to continue in a manner which promised for the trade in Cincinnati the most pleasing business conditions which could possibly be asked. In spite of the Government regulations regarding zoning, price limit, etc., the volume of business offered was such that in that important particular, at least, nothing remained to be desired; and the lesson of the severe weather did all that was necessary to a continuance of good business. With the recollection of this winter behind them, and with the united appeal of the various Fuel Administration authorities and the coal men themselves, the public, including consumers of all classes, promptly proceeded to start laying in coal for the season of 1918-19, almost before the snow of the previous winter had melted.

Not only domestic consumers, with needs limited by the consuming capacity of their furnaces, to a total of ten or twelve tons, were in the market for coal, but industrial consumers as well. Warnings were issued both by the fuel authorities and by the local gas company to the effect that consumers should not look for a supply of gas adequate to meet demands in extremely cold weather, and the experience of the previous winter amply backed up this warning. The result was something formerly unknown in the trade—a spring and summer season with a demand for coal which taxed every facility of the coal dealers and their connections to supply.

Not only was the current supply of coal inadequate to meet the demands booked by the dealers, but hauling capacity was also inadequate. In short, the state of the market more resembled that of a cold winter than the spring and summer season, proverbially dead with the coal trade. It was a common expedient with the trade, in consequence of this condition, to compile waiting lists of customers, notifying each when he could have his coal, and, in some cases, insisting that the full amount desired be taken when available, under penalty of losing his "turn"! This remarkable state of affairs, which might have been considered as totally impossible, actually lasted right up to the end of the summer, when consumers very generally had managed to secure all the coal they needed to take care of the coming season's fuel requirements.

COLLIER "TUCKAHOE" LOADING COAL AT CURTIS BAY COAL PIER, BALTIMORE & OHIO RAILROAD

Industrial storage was extraordinarily heavy, many manufacturers, by utilizing yards and other outdoor space, managing to pile up anywhere from two to six months' supply. This was the condition when the fall and winter season began, and when, on Nov. 11, the armistice was signed which caused the cessation of hos-

tilities and the immediate suspension or cancellation of war orders. And as scores of plants in and around Cincinnati were engaged on war orders, their fuel requirements showed a prompt diminution, in some cases amounting to complete cessation.

With this virtual elimination of industrial requirements, the trade has been further confronted during the winter with remarkably mild weather, such as to reduce consumption for heating purposes to a minimum. Thus, the storage supplies have been drawn upon but little, and unless the remainder of the winter sees some much more severe weather, and more of it, than the first part, many consumers, both domestic and industrial, are likely to carry over handsome balances of fuel, to an extent hardly paralleled in the past. As the first snow of the season fell on Christmas Day, and the subsequent cold snaps have been short and far from severe, this possibility has to be figured in considering the coming demand.

In attempting to forecast the state of the market, however, the question of how long it will take local industries to get back into peace harness, after being devoted for several years to war, is vital; and while it goes without saying that the resumption of peace activities will take place sooner or later, nobody knows just when it will be. In consequence, the trade at present is simply awaiting developments, fully aware that nothing can be gained by attempting to force matters, and confident that there will be an ample demand for fuel when conditions again become settled.

Good Business Outlook for 1919

R. A. Colter, secretary and treasurer of the C. G. Blake Co., and for the past year president of the Cincinnati Coal Exchange, comprising the leading members of the trade in its membership, takes this view:

"We are looking for good business when industrial concerns get around to a peace basis again," remarked Mr. Colter, speaking of prospects for 1919. "The weather, of course, has been and is against the trade, so far as demand is dependent upon consumption for heating purposes; and the disruption caused to manufacturing by the necessity of changing overnight from a war to a peace basis will take some time to repair. However, if the trade sits tight and waits for the change to take place, there will be a resumption of at least normal demand, the only question being just how long this will take. If the weather remains open for the balance of the winter, necessitating only a light consumption of fuel, there will be considerable stocks of coal carried over, as the case nearly always is when there is a mild winter, and this will tend to cut down spring business somewhat. Prospects in general, however, are good, and I see no reason for pessimism."

"We are optimistic," said J. C. Reilly, manager of the Queen City Coal Co., one of the larger domestic dealers of Cincinnati, with an especially large business in river coal. "Of course, present conditions are not such as to cause activity in the coal trade; but it will not be long before the reconstruction period is over. It will take us all, working together, to tide things over to normal conditions again, but there is no doubt that we will do it. Warm weather, coupled with the heavy storage demand which made business last spring and summer as good as it usually is in winter, is hurting domestic demand, but the industrial demand is off on account of the change from war to peace, which has affected many manufacturers seriously. Some of these manufacturers had a supply of coal stored for several months, and with the coming of peace they preferred to use this rather than save it for a reserve, as the general tendency was to cut down expenses and reduce investment.

"The spring and summer season, as I say, was remarkably good, keeping us at work fourteen hours a day taking care of the demand; and this demand was in effect that which would ordinarily wait for winter, so that there is no room for complaint on the score of the present dullness, in so far as it is caused by the extent to which people stored coal. Our supply of river coal was always good last year, on account of the use of artificial waves created by the use of the Government dams to bring coal down when the stage of the river might not otherwise have permitted it."

According to Thomas H. Richardson, manager of the Cincinnati branch of the Consolidation Coal Co., the heavy storage of coal last summer is the principal factor just now, as coal thus stored is being used to the exclusion of that offered on the market.

Consumers Have Learned a Lesson

"If these storage supplies are used up this winter, spring and summer business ought to be excellent," said Mr. Richardson. "People have learned to store their coal, and they have also learned to pay a fair price for it. The conditions of the past year, in these respects, did the trade a good service, and brought about a better appreciation in the minds of the public of the value and importance of coal than could ever have been instilled in any other way. It will not be as difficult in the future as in the past to induce customers to buy their coal in the spring and summer for the winter's requirements."

"The coal trade will be busy in 1919, as usual, but it will have to wait for business in general to get turned around, so to speak, before demand is resumed," is the way C. R. Moriarty, Western sales manager of the Cabin Creek Consolidated Coal Co., expressed his view of the situation. "The prospects for foreign business and other factors not at present clear will have to have time to develop themselves before manufacturers will feel like going ahead vigorously. Just now demand is limited, on account of reserve supplies of fuel in storage, and because concerns having coal coming on contract are of course able to get all they need under their arrangements. The railroads, which usually furnish a source of demand during the latter part of the winter, are in a similar position, so that there is hardly any quarter where one may look for business at present.

"The coming of peace, with the reduced coal requirements which result, among other things, will undoubtedly hit some small coal mines, and hit them hard. Small, high-cost operations were enabled to do business profitably under the drive for fuel which was on during the war, but this condition has now changed. With the resumption of normal conditions in the trade, including normal competition, business will seek its usual level. In the meantime, as there is no use in attempting to stimulate a demand that does not exist, the coal trade in general is showing great good sense in quietly awaiting the turn of things."

Suggestions for the Peace Conference

In Paris the representatives of the "associated" nations are trying to find a solution of the problems of the war. Here is a German suggestion taken from the Petition of the Six Associations—the League of Agriculturists (*Bund der Landwirte*), the German Peasant's League (*Deutsche Bauernbund*), the Christian German Peasant's Unions (*die christliche deutschen Bauernverein*), the Central Association of German Manufacturers (*Centralverband deutscher Industrieller*), the Manufacturers' League (*Bund der Industriellen*) and the League of Middle-Class Citizens in the German Empire (*Reichdeutscher Mittelstandsverband*). The reader will be interested to see how satisfactorily the coal fields and plants of Belgium and France are turned over to Germany. The proposal was made on Mar. 10, and May 20, 1915, the Petition being sent to the German Chancellor, Dr. Von Bethmann Hollweg, and to the Governments of the various Federated States of the German Empire.

"As a supplement to this memorandum, we must here lay special stress on the fact that the political, military and economic objects, which the German people must strive after in the interests of the security of their future, are inseparably connected with one another. . . . Hence it follows that even those demands which seem at first sight to possess a purely economic significance, must be viewed in the light of the urgent necessity for the greatest possible increase of our national strength and also from a military standpoint.

"This applies with special force to the demands, which are set forth in the memorandum, both (a) for the acquisition of territory suitable for agricultural settlement and (b) for the appropriation of the iron-ore district of the Meurthe and Moselle, of the French coaling districts in the Departements of the Nord and the Pas-de-Calais, and also of the Belgian coal fields. . . . Acquisitions, such as that of the iron-ore and coal districts mentioned above, are demanded by our military necessities and not by any means only in the interests of our manufacturing population. . . . The possession of larger supplies of coal—and, in particular, of coal rich in bitumen, which is found in great quantities in the basin of Northern France—is at least as decisive for the result of this war as the possession of iron ore.

"Belgium and North France together produce over forty million tons. Even today, as the British prohibition of coal exports (enacted on May 15) shows us, coal is one of the decisive means of political influence. The neutral manufacturing states must do the bidding of that belligerent who can guarantee a supply of coal. We cannot do this at present in a sufficient degree, and we are today already compelled to fall back upon the Belgian coal supply, in order not to let our neutral neighbors become entirely dependent upon England.

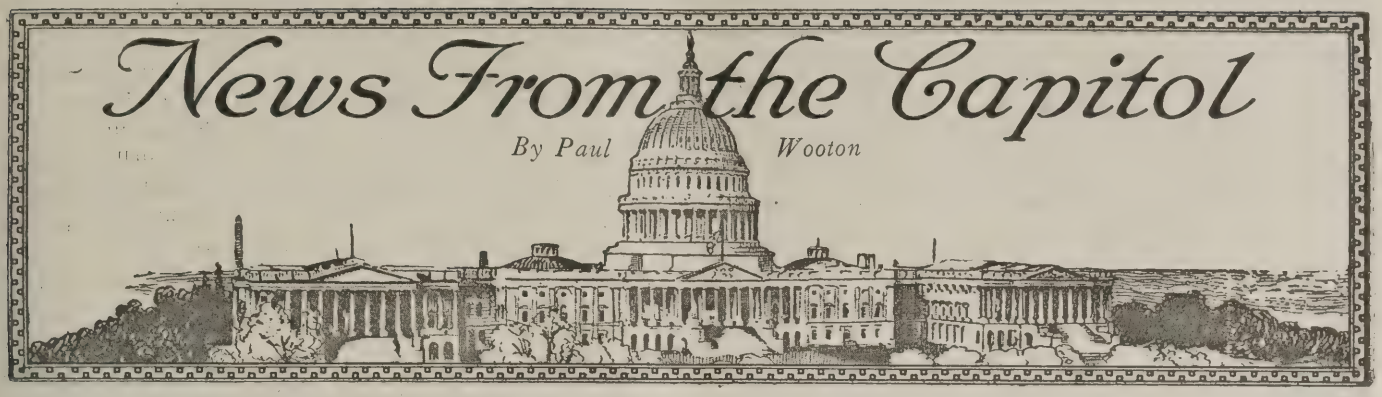
"It is quite probable that the systematic increase of the Belgian coal output, even during the present war, will prove a weighty factor in determining various neighbor states to remain neutral.

"That coal, which produces coke and gas, at the same time supplies the bases of our most important explosives, is presumably well known, as also is the importance of coal in the production of ammonia.

In benzol, moreover, it offers the only substitute for gasoline, of which we are short; and finally, it supplies coal tar, which yields (a) the oil fuel so indispensable for the Navy, (b) anthracite (anthracene) oil, the most serviceable substitute as yet obtainable at home for lubricating oil, and (c) naphthalene, the probable base of synthetic petroleum.

"It may in this connection be remarked that we should probably be unable to develop our destroyer and submarine warfare to the requisite intensity without an abundance of liquid fuel. The course of the war has so clearly proved the superiority of oil fuel over ordinary coal-firing in torpedo boats, that we should be guilty of unpardonable folly if we failed to base our future conduct on this experience.

"If our hostile neighbors secure possession of the oil wells, Germany must take care to secure for herself the necessary supplies of gas-producing and bituminous coal, and must in time of peace develop these until they constitute inexhaustible sources of oil, benzol, toluol, ammonia and naphthalene; and that, not merely in order to increase our prosperity in time of peace, but as an indispensable part of our equipment for war."



The Manifesto of the Intellectuals—German professors, diplomats and superior Government officials—dated June 20 of the same year, says less about coal but demands all (and even more than all) the territorial concessions demanded by the six associations. It, however, is quite specific as to how complete the conquest of the lands mentioned is to be:

"In order not to have conditions such as those in Alsace-Lorraine, the most important business undertakings and estates must be transferred from anti-German ownership to German hands, France taking over and compensating the former owners. Such portion of the population as is taken over by us must be allowed absolutely no influence in the Empire."

In dealing with Germany we are confronting a nation which can quote every moral phrase ever coined and appeal to every moral sentiment ever felt by humanity and then will lie, steal and murder without restraint. Germany expected to rob the world and then ask an indemnity for a war she started. Is any nation to be condemned for insisting, not on the right to rob Germany, but on the right to ask an indemnity from that Germany which started the war in the hope that it might be enabled to loot an unsuspecting world.

Local Coal Associations Would Help the Nation's Coal Industry

To carry out national plans for extending helpful service to the coal industry, the great need exists for local coal associations in several important districts. This fact became increasingly evident at the recent meeting of association secretaries, which was held in Washington. One of the principal areas which is without associations is southern West Virginia. The reason given for there being no associations in that region is because most of the operators are non-residents. The larger low-volatile operators reside in Cincinnati, while many of the high-volatile operators reside in New York.

Bituminous Price and Zone Restrictions To Be Lifted February 1

Coal prices and zones on soft coal will be abolished Feb. 1. An official announcement to this effect was made to the Fuel Administration Jan. 18. The restrictions are retained on anthracite for the present. The announcement carried with it the precaution that both prices and zones would be restored without notice if conditions should demand it. The significant feature of the announcement with regard to the Washington wage agreement reads as follows:

In the light of the so-called "Washington Wage Agreement" of October, 1917, whereby it was agreed to continue the wage scale then agreed upon during the war, but not beyond Apr. 1, 1920, the wages of mine workers should not now be reduced, and it is expected that whatever prices are asked or secured for bituminous coal between now and the promulgation of peace will be based upon the present wage scale.

Along with the zones and prices go the district representatives. The district offices in the Fuel Administration will be kept open until Feb. 15, so that records can be brought up to Feb. 1.

Denies That Railroad Administration Will Attempt To Break Down Coal Prices

Prominent among the many important announcements made recently is the statement of the Director General of Railroads outlining the policy to be pursued in the purchases of locomotive fuel. Director Hines takes occasion to deny that any effort is being made by the railroads to break down coal prices. The text of the announcement, which was issued Jan. 17, is as follows:

.The idea seems to have been suggested in some quarters that the Railroad Administration proposes to pursue a policy of so combining and using its purchasing bureau as to break down coal prices with the result of forcing a reduction in the existing rates of pay for mining labor; this is not the case.

It is the policy of the Railroad Administration to avoid at this time any undue concentration of its purchasing power of coal and to accomplish this purpose by permitting each road to purchase its own coal. It is further the policy of the Railroad Administration to require that all bids made and accepted shall be based on the existing scale of wages.

There can be no excuse, therefore, for the making of the claim that coal operators are forced to reduce wages by reason of the Railroad Administration accepting any prices which may hereafter be offered it for coal.

It is already fully understood that the railroads are not to use the car supply as a means of affecting prices. The policy on the other points above referred to is being clarified by the issuance of the following specific instructions which are being issued to make this policy clear to the purchasing agents of the roads:

"1. The railroads must not violate existing contracts or cancel contracts where the quality of coal is in accordance with specifications, without special consideration by the Central Advisory Purchasing Committee of the reasons for cancelling.

"2. The purchasing agent of each individual railroad shall buy the coal for that road under the supervision of the Regional Purchasing Committee of his region. In all requests for bids, the following paragraph should be inserted: 'It is distinctly understood that all bids are to be based on existing rates of pay for all mine labor, and the price will be subject to readjustment in event existing rates of pay are changed.'

"On contracts awarded or orders placed, the following paragraphs should be inserted: 'It is distinctly understood that the prices named herein are based on existing rates of pay for all mine labor and the prices will be subject to readjustment in event existing rates of pay are changed.'

"3. For coal which it is necessary to purchase for requirements prior to Apr. 1, 1919, the purchasing agents of each railroad should request that bids be submitted. They shall not undertake to fix the price of the seller's acceptance or make offers therefor, and shall agree only upon a price that shall be contingent upon the pay-for-mine-labor clause in paragraph 2. No negotiations for contracts for coal for delivery after Apr. 1, 1919, should be undertaken without first obtaining the approval of the Regional Purchasing Committee."

House of Representatives Passes Lignite Bill After Much Debate

By a vote of 182 to 85, the House of Representatives on Jan. 7, after acrimonious debate, passed the lignite bill. The bill already has passed the Senate and now goes to conference. The bill provides for an investigation by the Bureau of Mines to determine the commercial and economic practicability of using lignite in producing fuel oil, gasoline substitutes, ammonia, tar, solid fuels, gas for power and other purposes. It carries an appropriation of $100,000 as passed by the House. The Senate bill carries an appropriation of $150,000.

It is the intention to put up a small plant to demonstrate from a commercial standpoint that lignite can be handled on a profit-making basis. According to Mr. Norton, of North Dakota, the idea is to locate the plant either at Hebron, N. D., or at Minot, in the same state, where there is a private briquetting plant which may be utilized. Mr. Norton made one of the principal arguments in favor of the bill. In part, he said:

Let me call your attention to the immediate and tremendous importance of developing this great natural resource of our country—lignite coal. It is estimated that in the United States there is more than a trillion tons of lig-

nite coal; more than one-third of all the coal in the United States and Alaska is lignite coal. Let me particularly mention just one feature of the possibilities in the development of this low-grade coal. Investigations that have already been made show that as a byproduct from a ton of lignite coal there can be secured about 4 gal. of light oils that can be used in internal-combustion engines. This means that the light oils from lignite coal, and that can be secured from it in briquetting processes, are sufficient to meet the needs of the United States for 150 years, whereas the known or estimated amount of gasoline that can be secured from the petroleum fields of the country will only meet the demands of the United States for about the next 25 years. That is one important feature of this work that will be more fully presented to the country by the experiments and investigation to be carried on under this proposed appropriation.

Another great feature is the transportation problem. Today there is being shipped from Ohio and from other distant fields more than 7,000,000 tons of bituminous coal to the State of Minnesota.

If this lignite coal industry is developed, if the way is pointed out by the United States for private enterprise to engage in this industry, as I believe it should be, instead of transporting coal 1500 to 2000 miles into Minnesota it will be brought down there from the great coal fields of North Dakota, which are distant only a few hundred miles. That *alone* will mean a great economic saving in transportation. It will also allow of needed conservation of coal in Indiana, Ohio and Pennsylvania, where the coal fields are being rapidly exhausted. Today throughout North Dakota there can be seen fields of this coal varying in depths from 20 to 40 ft. One of the principal items in any after-war program for progressive development in this country should be the development and expansion of the use of lignite coal and its byproducts. Up in Canada they have recently appropriated $400,000 to develop the use of lignite coal there. Have we not every reason to do more to develop the use of this product in the United States?

Representative Stafford, of Wisconsin, was the principal opponent to the measure. An extract from his remarks follows:

Here we have an example of the Government going wild in Government ownership. I contend that under the authority the Bureau of Mines now possesses, similar to the authority possessed by the Bureau of Standards—of making laboratory tests to determine the practicability of these various byproducts of lignite coals—it is unwise as now proposed by this bill that the Government should go into the business of establishing a commercial plant. Originally they sought $150,000, and now $100,000 is sought by this ambitious Bureau of Mines. If it were for the purpose of merely laboratory work, I would not rise here to oppose it, but when the Government for the first time in its history is attempting to establish a commercial plant to demonstrate to the country at large whether it is economical, practical, and profitable to sell these byproducts, I say in these piping times of peace we should call a halt.

Representative Wingo, of Arkansas, who led the fight for the bill, declared that it ultimately would mean a saving of $15,000,000 to the State of Texas alone.

War Trade Board Suspends Ruling Concerning Supplementary Ship's Stores

The War Trade Board has announced the suspension of the ruling heretofore enforced, requiring all vessels when making applications for bunker licenses to furnish particulars respecting quantities of bunker fuel, port, sea and ship's stores and supplies on board vessels and those desired to be taken aboard. Hereafter the filing of Bunker Form B9-a, Bunker Form B-10, Bunker Form B-11 and Bunker Form B-12 will not be required.

Bunker licenses will be issued in the same manner as heretofore, excepting no restrictions will be placed upon the quantities of bunker fuel and ship's stores and supplies desired to be taken by vessels. A new combination application and license form will be ready for distribution in the near future, but in the meantime applicants should submit applications on the regular forms (Bunker Form B1-a, if an original license is desired, or Bunker Form B1-b, if a supplementary license is desired), and all reference to the supplementary ship's stores appearing on the applications should be deleted.

Important Ruling on the Subject of Coal Confiscated by Railroads

An important ruling has been handed down by the solicitor of the Fuel Administration to the effect that an owner of coal confiscated by a railroad between Apr. 1, and Oct. 10, 1918, is not deprived by any regulation of the Fuel Administration in effect during such period, of any legal right which he may have to recover the purchasing agent's commission which he has paid or become obligated to pay on such confiscated coal; and that the payment of such commission by a railroad on the settlement for coal confiscated during such period is not prohibited by any such regulation. This ruling, it was announced, supersedes all interpretations inconsistent therewith previously issued to individual railroads or coal companies.

Urges Formation of Statistical Branch for Each Local Coal Association

A statistical branch for each local coal association is being urged by C. E. Lesher, the geologist in charge of the coal division of the United States Geological Survey. This will be necessary, Mr. Lesher says, if the industry is to have at its disposal the most comprehensive statistics. During the war, the coal industry has had the advantage of very complete statistics made possible by the organization of district representatives. The district representatives of the Fuel Administration will discontinue their reports very shortly. This makes it necessary to get local statistics from the coal associations.

Some of the functions of the Fuel Administration probably will continue until July 1. The work of all of its district representatives, however, probably will be discontinued early in February.

Counsel Chosen for Senate Committee Investigating Hard Coal

William Wilhelm, an attorney in Pottsville, Penn., has been selected by Senator Vardaman, the chairman of the Senate Committee on Manufactures, as counsel for the committee in its anthracite investigation. Mr. Wilhelm, during the course of the present inquiry, made a number of sensational charges as to the methods being employed by anthracite operators. He is the author of drafts of legislation providing for Government tenure of percentage of anthracite coal lands; the prohibition of coal shipments when the royalty exceeds 50 cents a ton and the control of leases on undeveloped or abandoned coal lands.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

On Jan. 29, at Wilkes-Barre, Penn., a three-day convention of the insurgent organization of District No. 1 is scheduled to begin. The men in that district are in hopes that delegates will come from the two Southern anthracite districts, Nos. 7 and 9.

The Delaware & Hudson Co. has conceded the demands of its Grassy Island Colliery men, at Olyphant, Penn., and has agreed to pay for work on rock to 40 miners and 60 laborers under the agreement of November, 1916. This additional compensation will date back from the day on which the agreement was signed. A large number of consideration miners also will receive similar arrearages. The employees of the colliery voted on Jan. 12 to go back to work.

Payment for Gangways Independent of Size

The Conciliation Board in the anthracite region has been battling with the question, What is a gangway? The Delaware, Lackawanna & Western R.R. Co., Coal Department, apparently caused certain places to be driven narrower than the regular gangways, for which gangways a certain price had been established. They used these narrower places as gangways and declared that as these places are narrower the price of gangways did not apply. They argued, somewhat reasonably, that the work of the gangway driver determined the price rather than the purpose for which the place was driven.

The umpire said—somewhat testily it would seem—that "he understands fully the difference between gangways and airways, and, while he admits that the passages in the controversy were not as wide as the usual gangways, he asserts that the tunnel was used for that purpose and he refuses to read into the language of the anthracite wage agreement 'meanings that were clearly not in the minds of the parties who made and signed these contracts.' "

Gangway by Any Other Name Will Cost as Much

He also declared that coal operators cannot evade the payment of specified wage rates by calling an occupation or a place by some other name. That decision seems somewhat like a saying that another wise man recently delivered. He said that now the consumer, by careful stoking, much expenditure and skill, made 1500 lb. do the work of a ton, he should be required to pay a full ton rate for every 1500 lb. of coal received. Few of those who read that remark reacted favorably to it, nor can one react with favor toward the suggestion that the price for excavating a narrow roadway should be the same as for driving a wider place unless there were special conditions modifying this simple proposition. Frequently, it must be added, a wide place can be driven more easily than a narrow one and men are only too anxious to drive places wide, where they are paid for the coal secured. It would seem this was not true at Hallstead Colliery, or why was the price for a narrow airway made less than the price for a wide gangway? The decision of the umpire is made retroactive.

A driver at the Oneida Colliery, of the Lehigh Valley Coal Co., near Freeland, Penn., caused the death of two mules, and was discharged. The other drivers at the mine went on strike Jan. 16, alleging that the discharge of the man was not for his carelessness in taking the mules into the interior of the mine, but because he had been active in union circles. The strike lasted only one day.

President Kennedy in District No. 7 says that some soldiers and sailors in the anthracite mines have been refused their former positions. He says that they all must be reinstated and he will take the matter up with their employers.

In West Virginia Allen Bumpus, a colored miner from Republic, who claims the champion coal-loading record of the Cabin Creek field, was taken off a Kanawha and Michigan train at Charleston, W. Va., charged with ownership of a suitcase full of whiskey. He denied that he was the owner of the suitcase, but was haled before the justice on a Yost law charge.

More trouble has occurred at Drumheller, Alberta, Canada, a coal center already celebrated for production and labor trouble. The Drumheller field is second only, in Alberta, to the celebrated Crowsnest Pass field. Its production slightly exceeds that of the Lethbridge district. Consequently its labor troubles are of importance. It appears that four mines at the village of Wayne had unusually dirty coal. Commissioner Armstrong ordered the operators of these mines to pay 12c. per inch per lineal yard for the removal of this impurity and made the new rate retroactive from June 15 last. The operators declared they could not operate the mines with this handicap, and accordingly they closed them down.

The miners declare that the mines were shut down to beat the Commissioner's decision and not because coal mining under it was unprofitable. They alleged that the operators had other mines that could fill the orders of the mines at Wayne. There are 600 men idle now, and all the men in the Drumheller district are thinking of engaging in a strike if the mines are not reopened under the conditions prescribed by the Commissioner.

At Lethbridge, Alberta, a strike is threatened if two Japanese recently employed at the Galt coal mines are not discharged. At Sydney Mines, in Nova Scotia, the coal haulers are requesting an increase of 15c. per load of the miners. The Amalgamated Mine Workers of Nova Scotia has decided to let the contract for the lowest figure. It is expected that the latter organization will soon merge into the United Mine Workers of America, the men in the mines being desirous of affiliation, and the companies making no protest apparently. Formerly the corporations feared that the United Mine Workers of America might use its power to the destruction of the prosperity of the Canadian mines and to the advantage of those of the United States. They have been persuaded that the district union will have such a degree of autonomy that the dreaded result will be avoided.

About 9,500 mine workers will be affected by the change. The secretary of the Amalgamated Mine Workers is anxious to induce the legislature to amend the compensation law so that the companies will be obliged to compensate the 50 checkweigh men appointed by the men and paid by them.

Faith of Union Not To Be Impugned by Contract-Breaking Strikes

That officials of District 17, United Mine Workers of America, mean business in discouraging wild cat strikes was demonstrated recently in the Fairmont region when 300 miners employed by the Hutchinson Coal Co. at Mt. Clare, who had gone on strike without any authority from district officials, were ordered back to work. When H. E. Peters, in charge of the Fairmont office of the mine workers' organization, upon investigation found that the miners had violated their contract, he called a meeting of the strikers and informed them that they must return to work as they were violating a signed agreement. The striking miners were told that the charter of their local would be revoked unless they lived up to their agreement. Union officials are determined that there shall be no violation of contract on the part of local organizations as it casts discredit on the whole union.

Will Wages Increase in Peace Industries?

THERE is a small section of the public which says that wages must come down. It is more likely that the lower wages will rise till they get leveled up to the higher wages. As a result the average wage will increase. This will keep average prices up even though war industries may have to accept lower margins of profit.

The unionized industries have forced wages up and compelled working men, union and nonunion, to pay them; for the consumer pays the increased wage, and what are workers but consumers? During the war industries were developed by the payment of high wages, and the workers in industries that were principally of value in peace were made to stand and deliver. But a new time is at hand. The peace-worthy industries are anxious to recover the men they have lost and to secure the labor of disbanded soldiers. Unless they pay a wage equal to the war-worthy industries at points adjacent (where these are working steadily) they cannot get men.

So there will be a readjustment, still upward. Those who have a desire to buy should buy now before the price rises; for industries only suited to peace will raise prices, and the industries that are fostered by war will, like the rest, have to pay them when it buys such products. This will help sustain such war-worthy industry prices, even where margins of profit are reduced.

There Are Pleasures Even in a Strait-Jacket

THE Boston Fuel Committee on Jan. 10 removed all the restrictions that had up to that time been placed on retail distribution of coal, except the one relating to the maximum price at which coal may be sold. Even this regulation Washington has just revoked. The retail trade is therefore free. With what degree of pleasure does it greet its freedom, seeing that it has learned that there are some real benefits in strict regulation?

The retailer found in it restraint, it is true, but also support. He is now hunting around for some methods of maintaining that support. If the retailer cannot find such methods he, at least, is expecting to find some other ground for hope; for good habits have been formed, and dealers have been indoctrinated by a year of practical experience. Surely some of the supporting helps of strict regulation may still remain with the coal dealer even after he is free from Governmental control.

For free he is. The local fuel administrators admit that there is no further need for their services. It must be true, for such an admission is usually grudgingly made by bureaucrats. Those directors and tutors of the coal industry have even shown their confidence that their work is finished by presenting their resignations. Not only in Boston is this true. In ten days administrators the length and breadth of the land will be laying down their duties, meanwhile excusing the retailers from any allegiance to their behests.

Few clouds are without a silver lining. Behind all the fussy details and multiple annoyances of such careful supervision as has been placed on the coal men are disguised some real benefits which the retailer as well as the operator has not been slow to realize.

Dealers are beginning now more than ever to apprehend the entire cost of the service they have been performing for the public in all its many details. If, when competition is keen, you can only manage to close your eyes to the cost of the service you are rendering, you are quite likely to reckon it at a low figure. Now that the retailers know closely the cost of the accommodation they are affording the consumer, they are likely to have a price, a stable, inflexible price, that will not change, at least markedly, when a much-desired contract is in the balance. The expression "shading of prices" was always an unfortunate one. The consumer ever felt that a shaded price was the mark of a shady retailer. He never quite believed in the dealer who had a price which varied with the reciprocal anxiety of them both to land a contract. The consumer preferred to buy with his eyes shut and was averse to the notion that he was liable to be victimized if he did not manage to arouse a semblance of competition.

Will the dealer now stick by such a price, the sum of his items of expense plus a fair profit? During the war he had to do so and he was pleased so to do. He linked the fair and stable price with the service of his boy at the front. He coupled Government regulation with the even stricter military discipline of the army ranks. He felt it put the Stars and Stripes a little nearer the Rhine. But now it is different. He is free, and the urgency of patriotism is not so plain or so pressing. Will he now base his price on the cost of the staple, freight, wharfage and delivery plus a profit, or on what he thinks he can get his customer to pay, be it much or little?

Will he, moreover, now he is unregulated by anything other than law, reason and conscience, cease raiding his neighbor's territory and taking from him the customers his rival has secured. Will he, as before the war, haul coal to the customers of another man regardless of distance and even of loss? Aggressive business of this sort creates mutual dislike, counter raids and ill-considered reductions in price. It is shortsighted, futile and demoralizing. With the habit of keeping strictly to his own customers, and with a knowledge that the trip into his neighbor's territory will cost him so many dollars and cents, will he not, wiser now than before, avoid "head-hunting expeditions?"

And then again as to credits. Many retailers feel that they will never again have to keep so much money in "Accounts Receivable." The public has learned the art of prompt payment, and the dealer is little disposed

to let it forget what it has learned. The retailer would rather keep his money in a reasonable stock of coal than expend it in extending credits to his clients. He hopes that, in this matter also, the excellent condition of affairs will not end with the war.

These are matters directly under the retailer's control, but the attitude of the public to the retail dealer is not so closely at his command. The public is beginning to recognize, so the retailer thinks, that the charges of the retailer are based on substantial services. They do not represent merely profiteering. An outside impartial authority, a representative of the public and not of industry, stepped in and regulated the prices the retailers should charge. The authority, skeptical at first, discovers that the prices charged are fair and *have* been fair. Surely the loose accusations of the public must now cease.

These are some of the embers which the retailer hopes to save from the expiring system of fuel regulation. To let them die for want of fanning and fostering care would be the height of folly.

Inadequate Production With Six-Hour Day

BRITISH miners are exhibiting a strangely illogical point of view. Coal in Europe is in terribly short supply. There is therefore a great demand for the work of the miners. There is some doubt, however, whether all will be kept busy because there has been a lack of mine development during the war. When there were no men to fill large extensions of the mines the Government frowned on development work. Every extension demanded labor and yet added little or nothing to production. It was felt that the mine-extension problem could be well left till after the war. The consequence is that with Europe calling loudly for coal and with men to work it becoming numerous, production is halted for want of working places.

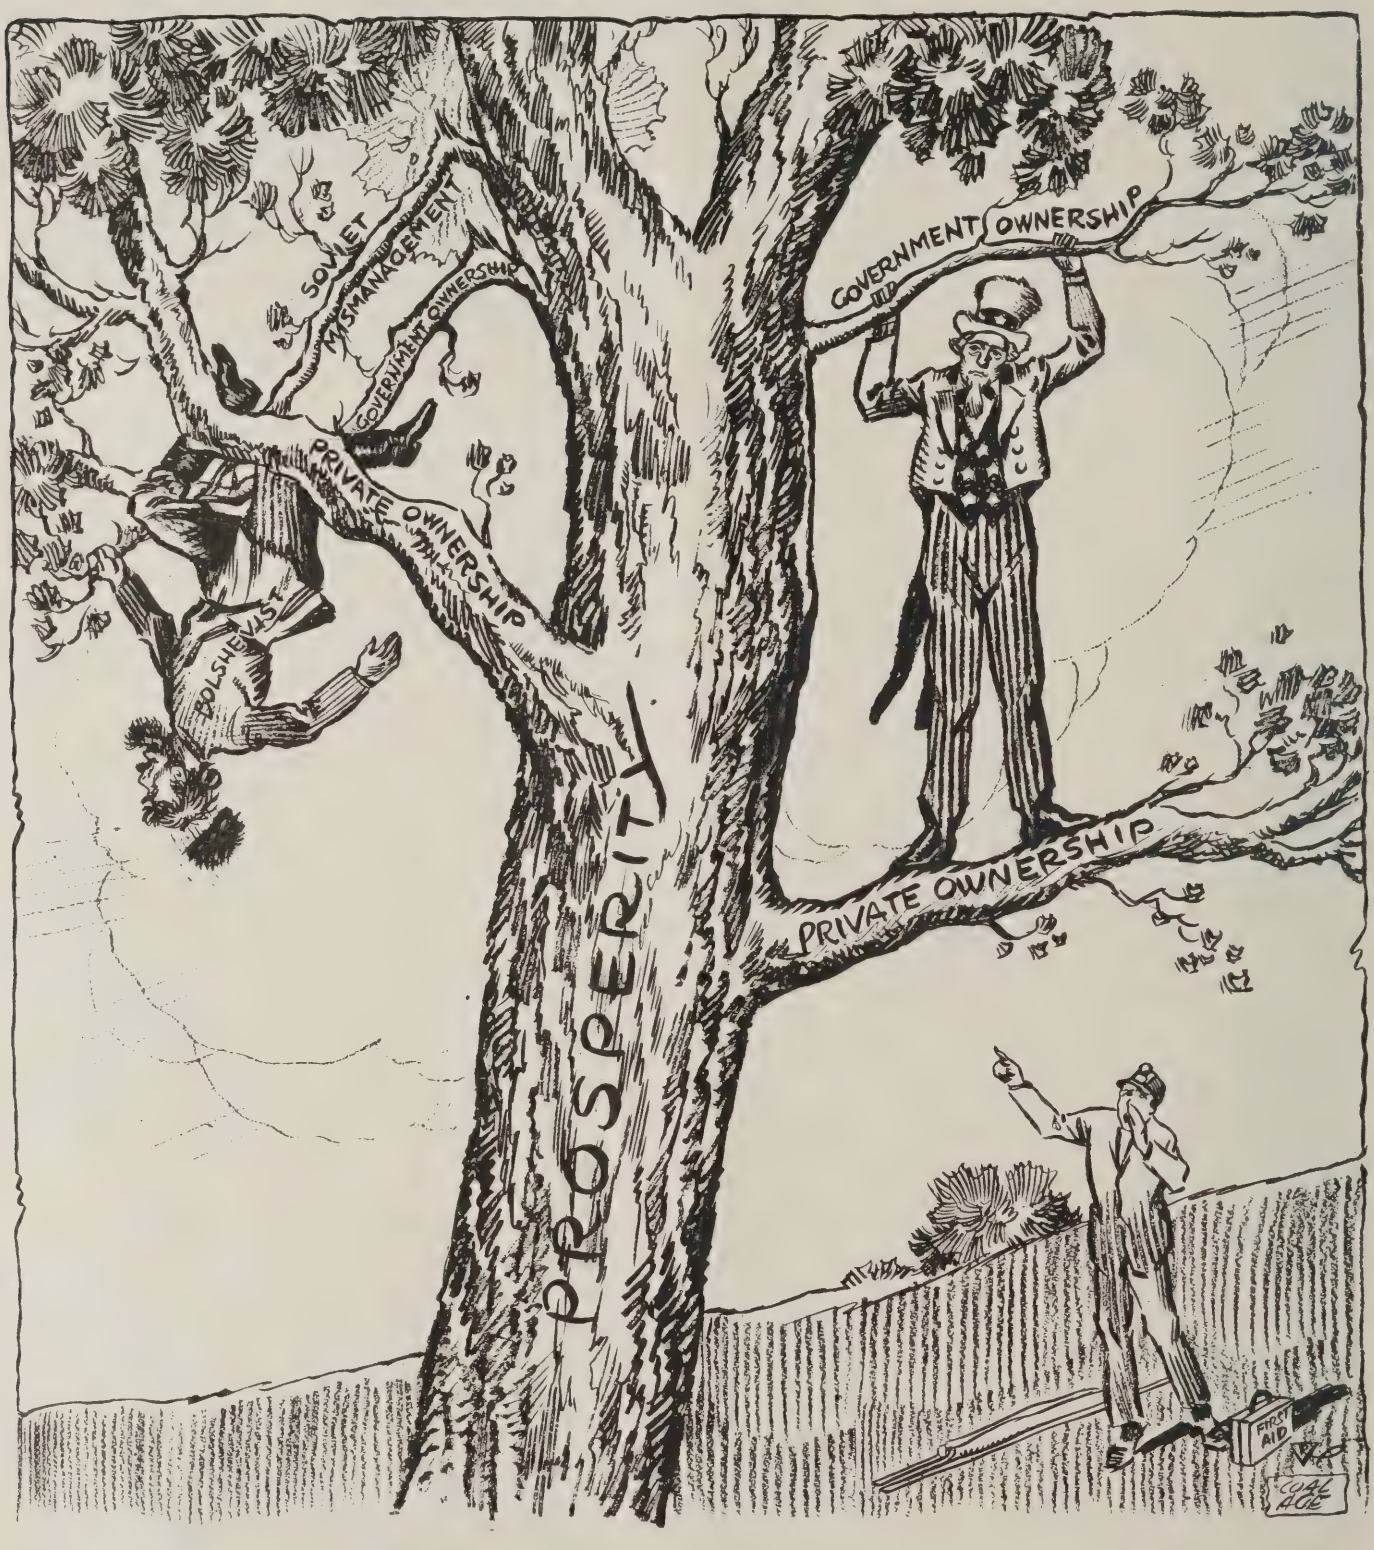
Consequently, if men are idle the fault is not in the lack of business, but in the restriction of opportunity for labor. The time when that opportunity will be available will be delayed if mine development is slow, and it will surely be slow if the hours of work are fixed at six per day. Given a six-hour day Great Britain will be hard pressed to meet the demands of business. European industry will suffer. Men will be out of work, or the population will go cold. Some will say that neither of these alternatives will happen, for the United States will supply the coal. In that event the absurdity of restricting production, from a British point of view, will be no less evident. The miner will be handing British markets over to his competitor. Such infatuation as that of the British miners well merits a hard fate. Just who will suffer most and who will gain most is not clear—but it will not be Great Britain.

At its coming Southport meeting the Miners' Federation of Great Britain is expected to ask for increases of from 30 to 50 per cent. and a six-hour day. The miners complain that prices have increased during the war 120 to 130 per cent. and wages only 75 to 83 per cent., the maximum wage now being 12 shillings and 5 pence, or about $3.02 a day.

The output of the average British mine worker is not such as to justify much more than the wage named. Perhaps it is unjust to say it, but most of them appear barely deserving of an increase to which only a larger production would entitle them. We would not, however, essay the unenviable task of determining who is mostly to blame, operators or miners, difficulties in working conditions or a meticulous desire for a No. 1 product.

So much for the wage, let us turn now to the number of hours worked per operating day. If, by working an eight-hour day, there should result an excessive coal output at any time, a few days of idleness every week would be the appropriate remedy. Why try the short-time remedy now when there is no disease? Why apply it at any time when work is plentiful. In fact, why apply the short day even in slack times? After all a whole holiday is better than several extremely short days.

There are some that are complaining that an eight-hour day at the face means a ten-hour day, bank to bank. That is extremely unfortunate. Why cannot the operator cure this undesirable condition by a man trip? In fact it seems that at every extensive mine the man trip is a necessity and an economy, if not for the operator, at least for the industry. The British miner does a short day's work. Can he feel worried about that fact when the operator who employs him views it with complacency and makes the miner oftentimes trudge farther below ground than he trudges on the surface?



It would appear that the unreasonable attitude of the British workman, in face of a shortage at home, should furnish the American exporter with an opportunity, at least, in South America if not in Europe. A six-hour day will prevent developments as well as production. Men, who in the face of need will shorten hours, will do worse—they will render those hours of minimum productivity. The chance is now good, if ever, to put a shaft through the mail of the British export trade. With restriction in working opportunity, reduction in hours worked and deliberate loitering on the job—a trinity of handicaps—how can Great Britain continue to hold her own in the Brazils, the Argentine and the Caribbean?

Mine Workers from Enemy Countries

MANY operators have men in their employ from enemy alien countries and have found these men not lacking in willingness to do a good day's work and thus support the national cause. Nevertheless these men are troubled. They left behind in the country of their birth, a father and mother from whom they learned and inherited those qualities that have made them useful and respected. They do not know what has become of them.

The American Red Cross has a Bureau of Communications with division, state and county headquarters, and through it letters of a personal character can be sent without expense to people residing in enemy countries. If you would help any of your employees desiring to get in touch with the home folks, establish communications with the nearest Red Cross Chapter, get blanks, and have them filled out correctly. Answers can usually be expected from Europe within two or three months' time provided the persons are still alive and in the place addressed.

Better Wait Till the Limb Gets Stouter

The Russian Bolshevist reached for the Government Ownership limb thinking it would carry him. It failed. As he had left the strong support of Private Ownership, and couldn't get back to it, if he really wanted to, he tried Soviet Mismanagement instead. It snapped like a rotten limb, letting him fall to the ground.

Government Ownership is rule by one set of politicians and Soviet Rule is rule by another set. Both will be a failure till men are wise enough to run somebody else's business as well as their own and generous enough to work as hard for the public as they will for themselves.

DISCUSSION BY READERS

Zoning System of Coal Shipments

Letter No. 2—After reading the letter of Ernest B. Ligny, *Coal Age*, Dec. 19, p. 1132, I can hardly refrain from offering a few comments on the matter he has presented. While there is no doubt but that the zoning system established by the Federal Fuel Administration imposes some burdens on a few individual cases, there are two viewpoints from which the question of its benefits should be considered.

Such are the environments of the coal industry in the United States, that the business is and has been in an awkward shape. Competition is strong and the differences in the amount of capital invested by different operators and companies is so great that the successful operation of a coal mine, today, is largely a question of the survival of the fittest. By that I mean those organizations that have the greatest financial resources will overtop and eventually absorb the business of their less fortunate competitors.

Zoning System Has Restricted Unfair Dealing

It would seem that there can be no question but that the zoning system, relating to the marketing of coal, has restricted much unjust and unfair selling of coal, by certain operators, at prices below the actual cost of its production. This will apply particularly to districts lying outside of their legitimate territories.

Allow me to ask, What would be the result if the Empire Coal Mining Co., operating at Bream, W. Va., were permitted to sell its coal in Indiana. While the benefits to that company would be far less than the injustice done to Indiana coal operators, a still greater injury would be done to the coal industry at large, owing to the fact that many of the local Indiana mines would be forced to suspend operations, in order to avoid bankruptcy. The chief benefit of the zoning system is that it prevents large corporations from unloading their surplus production in an outlying territory, too often at a positive loss, in order to keep their mines running on their regular contracts. It is not assumed, however, that this applies to the company just mentioned.

Looking the situation squarely in the face, one finds that it is illegal for operators to combine in the fixing of a standard selling price for their product, which can only be done by the Government in the interest of all. Operators well know what is the average cost of production after making due allowance for overhead charges, depreciation of equipment, etc. And it goes without saying that no government desires that industrial products shall be sold at a less price than the cost of production to which a reasonable profit is added. The fact of the matter is that the root of the trouble lies in the lack of organization controlling the industry.

While many of the members, myself being among the number, who belong to the United Mine Workers of America, have suffered injustice by reason of the union, the principles of the organization, it is generally agreed, are all right. My opinion is that if coal operators were organized in a similar manner, and their activities controlled in the interests of all their operations combined, much good would result by reason of the unity thus established.

Permit me to refer, here, to the Rockefeller Foundation plan as being the only method that will insure justice to operators and employees alike. Let me urge that now is the opportune time, in this reconstruction period. Only by the adoption of some such measures can stability be assured to the coal business of the country, bankrupt methods be eliminated and the industry put on a healthy basis.

It is my impression that the British Government fixed a minimum wage for their miners about eight years ago, and I believe that there will soon be a minimum wage established in the United States. Following that, a minimum selling price will be fixed to conform with the conditions in each coal-producing district.

In my opinion, the zoning system of the shipments of coal, established by the Fuel Administration, was an effort to systematize and economize the distribution of the coal resources of the country. Let coal operators cooperate along the same line and, by organization, establish a unity of action that will develop the industry and invite the investment of much capital that at present must lie idle because of the unrestricted practices of those who have larger resources. W. H. LUXTON.

Linton, Ind.

Locating the Coal Beyond a Fault

Letter No. 8—Regarding the question of locating the coal beyond a fault, described by a correspondent in *Coal Age*, Oct. 24, p. 797, I am of the opinion that the fault mentioned is a downthrow. I also believe that the coal struck in the two boreholes sunk from the surface, beyond the fault, belonged to the X-seam.

It is true that the thickness of the coal, as shown by the results of the boring, does not correspond to that of the X-seam in the workings where the conditions were normal. But, as has already been stated by another correspondent, this reduction of the thickness of the seam has probably been caused by the great pressure incident to the disturbance when the faulting of the measures occurred. It will be noticed that the correspondent informs us that the appearance of the strata, at the face of the main heading in the fault, indicated that the formations had been subjected to a tremendous pressure, as the rock there is very much broken.

My own experience with faulted strata has been gained in the Carbonado coal fields of the State of Washington. The district is noted for its numerous slip and overthrust faults, dykes, pinches, horsebacks, etc., which are characteristic of coal fields where the strata have been contorted and twisted into numerous

anticlines and synclines such as exist in that field and, likewise, in the pitching seams of the Province of Alberta, Canada.

When a fault is encountered my policy has always been to note very minutely the nature of the hanging and footwalls to ascertain if there is any small lead that could be followed. In the absence of any such lead or stringer of carbonaceous matter, it has been my custom to secure samples of the rock at the point where the coal pinched out or the slip occurred. By studying these samples of rock carefully, it has been possible for me to correlate them as belonging to strata known to overlie or to underlie the coal, thereby showing the fault to be a downthrow in the former or an upthrow in the latter case.

Referring to the case in hand, it seems strange that, after going to the expense of drilling two boreholes, a log has not been kept showing the strata passed through. In that case, there should be no great trouble in correlating the different formations, which would have enabled them to arrive at a definite conclusion in regard to the coal struck in these holes.

It is strange, also, that when there was uncertainty in regard to the coal struck, the drilling was not continued to a depth of 50 or 60 ft. below that point, before dismantling the drill and abandoning the hole. The finding of a second seam of coal, at a depth more or less closely corresponding to the distance between the two seams in the workings, would then have given them practically definite information regarding the situation.

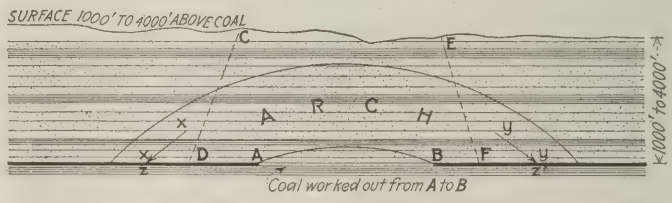
Cassidy, B. C., Canada. J. W. POWELL.

The Rock Arch in Mining

Letter No. 1—Interesting conditions, developing what are known locally in Utah as "bounces," are described in an article by A. C. Watts, *Coal Age*, Dec. 5, p. 1028. Mr. Watts describes certain occurrences observed during the driving of a slope in one of the mines of the Utah Fuel Co., "in virgin territory, several hundred feet away from room workings and fifteen hundred feet distant from the nearest pillar operations.

Mr. Watts attributes the excessive pressure, developing bounces and throwing the solid coal violently from the face, to the existence of two approximately parallel faults, which were passed through in driving the slope, stating that beyond the second fault the phenomena apparently ceased.

FAULTED MEASURES PRODUCE ONLY NORMAL PRESSURE



The explanation suggested by Mr. Watts does not seem to account adequately for the conditions described. The cutting loose of a block of ground by fault planes, thereby giving it freedom of movement and allowing its whole weight to rest directly on the coal bed, would hardly explain the great increase in pressure required to break the coal from the face or cause it to flow into an entry or other excavation.

In my opinion, the increase in pressure due to this cause would be limited in extent and would not be found to exist from one fault plane to the other. In other words, the pressure on the coal bed between these fault planes should theoretically be no greater than the normal pressure to which this coal is everywhere subjected by the weight of the overlying rock mass.

Some fifteen or sixteen years ago, in discussing conditions affecting mining operations in the mines of the Utah Fuel Co., I suggested to W. G. Sharp, who, if my memory serves me, was then general manager of the company, and to the late Robert Forrester, then mining geologist to the company, that severe squeezing conditions, giving evidence of very great pressure, might be encountered at considerable distances from where any pillar robbing had been done, and at distances remote from any of the workings affected by the drawing of the pillars.

An increase in pressure, in circumscribed areas remote from actual workings and in what might be termed "virgin territory," it seemed to me, might occur by the transmission of pressure, produced by the weight of the rock mass above such workings, along resultant lines of force such as develop in arched structures. That is to say, the weight of the rock mass above pillar workings will be largely sustained by transmission of the stresses due to the weight to points more or less remote from the workings, unless breaks occur in the rock mass and extend practically to the surface. If the rock mass contains thick beds of sandstone capable of sustaining great sheering stress, the weight of the rock mass will develop resultant stresses just as though it was in reality an arch. Unfortunately, it is impossible to predict the curvature or span of such arch stresses.

The accompanying sketch illustrates this principle, and is intended to represent conditions where the strata

ILLUSTRATING OVERARCHING OF STRATA

overlying a nearly horizontal coal bed are, say 2000, 3000 or 4000 ft. thick and contain thick ledges of hard sandstone, corresponding to the "Book Cliffs" district, in Utah. The sketch shows the coal bed *ZZ'*, as having been mined between *A* and *B*, the curved lines indicating an imaginary arch supporting the rock mass lying above.

Possible sheering or breakage lines are shown by dotted lines *CD* and *EF*. If the rock mass should break along these lines, there would be no transmission of stresses by arching, but the weight of the whole mass *CEFD* would then rest on the comparatively short distances of solid coal *AD* and *BF*, producing a greatly increased pressure between these points.

If, however, the rock mass does not break, the arching of the overlying strata will transmit the pressure far beyond the points *D* and *F*, as indicated by the thrust arrows *xx* and *yy*. The result will be an enormous increase in the pressure on the coal at *Z* and *Z'*. This increase in pressure cannot, of course, be determined, being modified by the pitch or dip of the formation and the possible existence of fault planes along which movement may result.

In the operation of mines in the anthracite region of Pennsylvania, it has frequently been observed that a squeeze developing in a relatively small area of mine

workings will often be quickly followed by another squeezing action, at a point so distant from the first disturbance as apparently to have no connection with it and, perhaps, separated by territory as yet unworked.

On a number of occasions, my attention has been called to occurrences of this kind, and I have no doubt that they have been caused by a transmission of pressure due to the natural arching of the strata when a break does not extend to the surface.

For this reason, it seems important that, in all mining operations in which the coal lies at a great depth below the surface, the pillars left for the protection of slopes, entries, etc., even though remote from pillar workings should be made of great width or thickness, as a precaution against the possible closure of such openings by a concentration of pressure due to arching.

In the case described by Mr. Watts, it seems possible that a thrust, due to arching above the mined territory, may have been transmitted to the block of ground between the two faults mentioned. This being unsupported on its sides and free to move, would certainly transmit a thrust, in addition to its own weight, to the coal and produce the effects described.

While the normal average pressure on a coal bed, due to the weight of the overlying rocks, is about 1 lb. per sq.in., for each foot in depth; or, say 2000 lb. per sq.in., at a depth of 2000 ft. the thrust pressure developed by mining the coal is limited only by the crushing strength of the overlying rocks, which limits their ability to transmit such pressure without crushing or actually flowing.

This limitation may be assumed as being between 6000 lb. per sq.in., for relatively soft or weak rocks, such as slates, shales and soft sandstones, up to, perhaps, 20,000 (?) lb. per sq.in., for very hard and strong rocks, such as granite or trap. If this theory of the rock stresses produced by the unsupported weight of rocks above mined-out areas is true it is entirely possible, in the vicinity of mined areas, to encounter at moderate depth rock pressures as great as would be found normally only at depths of from 6000 to 20,000 (?) feet. H. M. CHANCE.

Philadelphia, Penn.

Efficiency in Firebossing

Letter No. 2—I was interested in reading the letter of F. G. J., in regard to firebossing, *Coal Age,* Dec. 19, p. 1133, and particularly in his reference to "men who have struggled from the bottom to the top, via the fireboss route." Speaking from an experience of 20 years, in firebossing, I believe there are few men who are fortunate enough to have the opportunity of climbing the ladder by this route.

The mine foreman, from my observation, is prone to regard the fireboss as a necessary evil. That is particularly true when the foreman has never been a fireboss himself. I regret to say that there are many of this type of foreman in our mines; they have not climbed to their present eminence by the "fireboss route"; and experience leads me to conclude that more efficient ventilation would result in our mines if that had been the case.

The treatment that the fireboss receives from the average mine foreman is not encouraging. Our friend who wrote the letter to which I have just referred suggests that the mineboss should teach the fireboss all he can so that he will be able to take his place and act for him in his absence. There are, perhaps, some foremen who will do this, but the most of them prefer to keep the fireboss at his own job. They are seemingly afraid of losing their own place if there are other men who are prepared to take it.

As our friend states, conditions and laws governing mining are different in almost every state. In Indiana, the law requires that every working place where firedamp is known or supposed to exist shall be carefully examined with a safety lamp, by a competent fireboss, immediately before each shift. The fireboss must leave, at the face of each place examined, evidence of his presence there; and no person is permitted to enter a mine generating firedamp, until it has been examined by a competent fireboss and found to be safe for work.

Practice of Firebosses in Indiana Mines

It is the custom of our firebosses to enter the mines at 12 o'clock midnight. Where there is more than one fireboss each man examines his own section, which takes him from four to six hours to complete. Believe me, the work he must do is not easy. While I have never seen or heard of firebosses being compelled to dig coal in their spare time, a few years ago I had to put in my idle days in setting timbers and clearing up airways, or doing other work of a similar nature. Now, firebosses are scarce; conditions have changed and, as a rule, the men are treated better than formerly.

Speaking of promotion, however, after holding one job two and one half years, there was an opportunity for getting a better place and I went after it, only to be told that I was all right where I was. That, naturally, did not satisfy me, and my advice to the fireboss who wishes promotion and is "passed up" for some friend or relative of the management, is to look at once for another place.

I will close by saying that the greatest efficiency, in firebossing, can only be attained when the fireboss is regarded as something better than a "necessary evil." In my opinion, a man should start at firebossing, and if he can produce the goods should be advanced as the opportunity offers. FIREBOSS.

——, Ind.

Letter No. 3—It is gratifying to note that the question regarding the work of firebossing is again up for discussion in *Coal Age.* While the remarks on this subject partake largely of the nature of those made a year ago when the question was treated along somewhat different lines, my attention has been arrested by the claim set forth in one letter: namely, that the fireboss should never, under any circumstances, be called upon to do anything else than his own particular work.

Now, I have no desire to belittle the importance of the fireboss; but I want to take exception to this statement of F. G. J., *Coal Age,* Dec. 19, p. 1133. He states, further, "The fireboss should be and is, in many mines and in many respects, as important as the foreman." The duties, difficulties and responsibilities of a fireboss, cannot compare with those of his mine foreman.

In a large mine, there is usually ample work for the fireboss to perform that will occupy his whole time. But,

in a small mine, it does not require a great stretch of the imagination to see that a fireboss will often have time to busy himself looking after a pump, laying a piece of track, setting needed timbers, or other similar work that must be done.

In the case last mentioned, that of a small mine, it is my opinion that a fireboss can rightly and properly be asked to do such work. All other workers around the mine are frequently called upon to do other than their regular work, and why should not the fireboss do likewise? Is a fireboss any better than an assistant foreman, who is often called upon to perform these extra tasks? Is he any more important or deserving of more consideration than the assistant to the foreman?

Before closing, let me say, in answer to the question propounded by F. G. J., in the fifth paragraph of his letter, by saying, emphatically, yes. A foreman certainly promotes efficiency when he starts a fireboss at other work for which he has ample time without interfering with his duties as fireboss. The foreman would certainly be promoting inefficiency, in the mine, if he did not do that, or lay the fireboss off when his particular line of work is completed. The fireboss would certainly holler if that was done. EDWARD H. COXE.

Pittsburgh, Penn.

Efficiency in Mine Management

Letter No. 1—Besides being humorous and, indeed, too true, the article entitled "Need of Efficiency in Coal Mining," *Coal Age*, Nov. 28, p. 983, touches upon a vital point in coal mining and, no doubt, in other allied industries as well. Who of us has not seen all and many more of the wasteful practices mentioned in that article?

During the continuance of the war, all industries suffered alike from labor shortage. The conditions we have experienced should cause us to realize, now, the need of more concentrated effort toward efficiency; and, in no industry, is this more important than in that of coal mining. Because of inadequate or antiquated equipment, many coal operations have been forced to shut down; whereas, had they been developed on an efficiency basis, they could have survived the conditions brought about by the war. Many times have I been severely criticised by friends and clients for the constant preachment of "efficiency." Others, I believe, have had a like experience; but happy is the man who can see light breaking in darkness.

REMARKABLE TRANSFORMATION QUICKLY MADE

One incident that I recall with some pride occurred when I was called by a friend to investigate a property in which he was interested. He gave me authority to go ahead, make improvements, changes, in fact, do anything that would make the mine pay. This mine had little in its favor, except a good grade of clean coal. Transportation was difficult; material, sky high; labor, hard to get and more difficult to hold. Development was at a standstill. A trip through the mine followed by a survey of the conditions was enough. To me, it was a revelation that the crisis had not been reached long ago.

Six months later—it seemed an incredibly long time—conditions were reversed. There were new houses for the men and uptodate equipment wherever possible; but the greatest fact of all was the contentment of the men. Though labor in that district was and is yet scarce, the mine has not lost a day since taking on its new life, and is now producing a startling tonnage. More remarkable yet, this transformation took place within the period included by the months of March and August of this year. "Efficiency" was the watchword and it has proved a boon.

MISTAKEN IDEAS OF EFFICIENCY

There are those, no doubt, who can preach efficiency to the extreme. One such case that recently came to my attention was that of a property employing 130 men and keeping three bookkeepers busy in the office. The answer to my inquiry forced a smile. "Oh! We are working out a pet scheme of one of the bosses. 'Efficiency,' he calls it; and a little slip must be made out every time we turn around. Last month it was necessary to hire seven men to go about and check up the other fellows, and these two extra pen-pushers must put it down in black and white.

"The other day, the big boss came to me claiming that our overhead charges were excessive. He had a bunch of papers, stacks of figures, crooked lines and what not. Before he finished he wanted to know what was the matter in the 7-N, stating that every ton of coal from that entry cost 18c. more than from other places in the mine.

"Then he and I went up in the air and, to make a long story short, I frankly told him that if he would come down to earth and hire another tracklayer in place of the nine or ten efficiency experts, I would get coal out of the 7-N for 18c. less than any other place in the mine. Perhaps that was going some, and I expected he would fire me for being too d—— fresh."

This is by no means an extraordinary incident; it is a case of misguided energy. A level-headed analysis of working conditions and a better understanding of men would have been successful, where a wrong application of a good thing brought only failure.

Golden, Colo. F. L. SERVISS, SR.

Freezing of Shaft in Winter

Letter No. 9—Regarding the discussion of preventing the freezing of a mine shaft in winter, let me say that the mine foreman or superintendent who has not yet learned to eliminate this difficulty in his mine has yet one hard problem to overcome. Conditions differ in every mine, in this respect, and each case presents a separate problem for study.

I well remember an incident that occurred some ten years ago at a mine where I was employed as fireboss. The winter was well advanced and the air, at the working faces, had gotten so poor that it became necessary to investigate and ascertain the cause. So, after completing my examination of the working places in my section that morning, in company with another fireboss, I started out to find what was wrong with the ventilation.

Knowing it to be zero weather outside, we proceeded at once to the foot of the downcast shaft and, to our surprise, found it almost completely blocked with solid ice. The opening through which the air was passing

into the mine was, to the best of my knowledge, 2 x 2 ft., giving an area of about 4 sq.ft. It was clear to us, at once, that here was our trouble, and we lost no time in getting to the surface.

The condition of the ventilation in the mine workings and its cause, as we had discovered it, was reported promptly to the foreman and superintendent. But I do not hesitate to say that, at that time, these officials were wholly ignorant in regard to the best means to be adopted to rid the mine of such a difficulty, and prevent the further formation of ice in the downcast shaft. However, four men were quickly dispatched to the shaft, with instructions to dig out the ice and wheel it back to some place in the mine where it could be stowed away, which proved to be no easy task, as will soon appear.

The Work of Digging Out the Ice

The downcast shaft, at this mine, was divided by a partition that separated the manway from the air shaft. Descending the stairs in the manway, the men sent to perform the work of cutting away the ice were obliged to take out a few boards in this partition before they could reach the shaft bottom and begin work. The air was so keen and the current so strong, that a man could not remain in the shaft longer than three minutes at a time, and it was necessary to take a turn about until the area through which the air was passing had been enlarged sufficiently to reduce the velocity of the current. Anyone who has had experience in a similar undertaking can understand that it was no pleasing task we had in hand.

Now, regarding the best means of preventing ice trouble in a downcast shaft, in winter, let me advise extending the exhaust pipe line from the fan house to the top of the downcast shaft. Then, from this point, carry two smaller pipe lines a distance down the shaft. A valve should be placed in the main pipe, which conducts the exhaust steam to the top of the shaft, and this valve should be closed when the steam is not required in the shaft, in more moderate weather.

Advice of Scotch Miner Taken

It was not long after the occurrence of this incident that a Scotch miner told the superintendent of this plan for avoiding the ice trouble, by conducting the exhaust steam from the fan into the shaft. The superintendent acted upon the suggestion at once; and, I am glad to say that, from that time on, no further trouble was experienced with the formation of ice in the shaft at that mine.

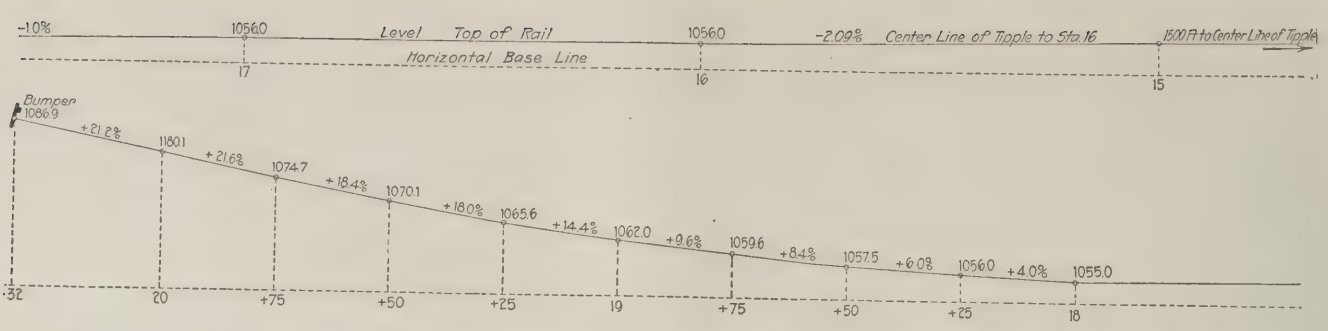
Before closing, however, let me warn any who may adopt this method of overcoming the ice trouble in a wet shaft, that it is necessary to keep the fan running at normal speed, in cold weather when ice would be formed in the shaft. I would even suggest the speeding up of the fan at such a time. This will not only give a larger volume of exhaust steam entering the downcast shaft; but it will increase the volume of warm air ascending the hoisting shaft and keep that shaft and guides in good condition. It is important to remember that if the night fireman is allowed to let his steam get low, and the fan is run below the normal speed, trouble will be apt to follow. The slogan to adopt is: A small amount of exhaust steam in the shaft is worse than none at all, as it will only assist the formation of ice at the shaft bottom and do more harm than good.

Poston, Ohio. J. H. Taylor.

Inquiries of General Interest

Calculation of Runaway Track

On the Wheelwright division of the Elkhorn Coal Corporation's mining properties, we have what is commonly called a "runaway track." This track starts from the cutoff switch at the foot of the incline leading from the tipple to the mine slope and is constructed on such a vertical curve that it will retard and bring to rest a car that may chance to get loose and run wild into the mine. The cutoff switch is always set for the runaway track.



Being up against this proposition, we have made some calculations, but desire to submit our results to the Inquiry Department of *Coal Age* and ask for their revision. What we desire to know is the speed at which a wild car, getting loose on the tipple and starting from rest at Sta. 0, which is the center line of the tipple and head of the incline, would reach Sta. 18, where the upgrade of the runaway track begins. Also, at what point on the upgrade of this track would the wild car be brought to rest. Following are the data entering into this proposition and necessary for the calculations:

As shown on the accompanying profile, the incline leading from the tipple has a uniform downgrade of 2.09 per cent. or from Sta. 0 to Sta. 16, 1600 ft. Then, there is a level stretch of 100 ft. to Sta. 17, followed by a 1 per cent. downgrade to Sta. 18, where the upgrade of the runaway track begins.

The profile shows the variation of upgrade, in 25-ft. lengths, corresponding to the vertical curve of the runaway track. In this calculation, assume a straight track from the head of the incline on the tipple to the bumper at the end of the runaway track, and a good condition of track throughout. Assume, also, a 55-ton car loaded with coal, the gross weight being 66½ tons. The estimated length of the runaway track is, as shown on the profile, 232 feet. Division Engineer.

Wheelwright, Ky.

The runaway car, in this case, moves under the action of gravity, which is resisted in part by a force known, in haulage, as the "track resistance." The accuracy of the calculation will depend on the actual track

PROFILE OF TRACK FROM TIPPLE IS SHOWN ABOVE, AND BELOW IS THAT OF THE RUNAWAY TRACK

resistance, which we will assume is 20 lb. per ton of moving load. There are three phases to be considered: (1) On the downgrade, the net force producing motion is the gravity pull due to the inclination, less the track resistance. (2) On the level stretch, there is no gravity pull, and the movement of the car is retarded by the track resistance only. (3) On an ascending or upgrade, the movement is retarded by a force F, which is equal to the sum of the gravity pull due to the grade and the track resistance.

This calculation is based on the work performed by the force F, moving through a distance or space s, being equal to the amount of energy stored or given out for any given change in velocity. If the forces act to produce motion, the change of velocity is $v_2 - v_1$. On a level stretch or an ascending grade, the forces act to retard movement, and the change of velocity is then $v_1 - v_2$.

Calling the force acting to produce or retard motion F (lb.), and the mass M of the car or its weight W_t (tons) and any two velocities considered v_1, v_2 (ft. per sec.), the two basal equations employed are the following:

Downgrade,

$$Fs = \tfrac{1}{2}M(v_2^2 - v_1^2) = 2000\frac{W_t}{2g}(v_2^2 - v_1^2) \qquad (1)$$

Level or upgrade,

$$Fs = \tfrac{1}{2}M(v_1^2 - v_2^2) = 2000\frac{W_t}{2g}(v_1^2 - v_2^2) \qquad (2)$$

Now, calling the angle of inclination a, the gravity pull, in pounds, is 2000 W_t sin a; and since the track resistance is assumed as 20 lb. per ton of normal pressure, it is $20W_t$ cos a; which gives the following expressions for the force (F), acting either to produce or retard motion, in the three phases mentioned:

Downgrade, $$F = 2000W_t\left(\sin a - \frac{\cos a}{100}\right) \qquad (3)$$

Level, $$F = 20W_t \qquad (4)$$

Upgrade, $$F = 2000W_t\left(\sin a + \frac{\cos a}{100}\right) \qquad (5)$$

Then, combining Equations 1 and 3, and solving with respect to v_2, which is the velocity due to acceleration by gravity through a distance or space s, on a plane whose angle of inclination is a, we have,

Downgrade, $$v_2 = \sqrt{v_1^2 + 2gs\left(\sin a - \frac{\cos a}{100}\right)} \qquad (6)$$

Again, combining Equations 2 and 4, we obtain for the retarded velocity v_2, after passing over a level stretch or distance s,

Level, $$v_2 = \sqrt{v_1^2 - \frac{2gs}{100}} \qquad (7)$$

Finally, combining Equations 2 and 5, we have for the retarded velocity v_2, due to ascending a plane whose angle of inclination is a,

Upgrade, $$v_2 = \sqrt{v_1^2 - 2gs\left(\sin a + \frac{\cos a}{100}\right)} \qquad (8)$$

It is necessary, first, to find the value of the expression in parenthesis for the given grade, which is 2.09 per cent. from Sta. 0 to Sta. 16, and the value, in this case, is 0.011. Then, assuming the runaway car, weighing 66.5 tons, starts from rest at Sta. 0, $v_1 = 0$, and $s =$ 1600 ft. Substituting these values in Equation 6, we have for the velocity of the runaway car, at Sta. 16,

$$v_{16} = \sqrt{2 \times 32.16 \times 1600 \times 0.011} = 33.65\ ft.\ per\ sec.$$

From Sta. 16 to Sta. 17 is level; $v_1 = 33.65$ and $s =$ 100 ft.; and substituting these values in Equation 7, we find, for the velocity of the car at Sta. 17,

$$v_{17} = \sqrt{33.65^2 - 2 \times 32.16 \times 100(\tfrac{1}{100})} = 32.67\ ft.\ per\ sec.$$

From Sta. 17 to Sta. 18 is a downgrade of 1 per cent. Hence, substituting the values $v_1 = 32.67$; $s = 100$; sin $a = 0.01$; cos $a = 1$ in Equation 6, we have

$$v_{18} = \sqrt{32.67^2 + 2 \times 32.16 \times 100(0.01 - \tfrac{1}{100})}$$
$$= 32.67\ ft.\ per\ sec.$$

On this stretch, it happens that the gravity pull is equal to the resisting track resistance and there is no change in velocity. The car has now reached the foot of the upgrade, which is 4 per cent. for a distance $s = 25$ ft.; and substituting the necessary values in Equation 8, we find for the velocity of the car at Sta. 18+25,

$$v_{1825} = \sqrt{32.67^2 - 2 \times 32.16 \times 25(0.04998)}$$
$$= 31.42\ ft.\ per\ sec.$$

In like manner, the velocity is found for each 25 ft. of distance and the respective grades shown in the figure, giving the following results: $v_{1850} = 29.58$ ft. per sec.; $v_{1875} = 26.91$ ft. per sec.; $v_{19} = 23.55$ ft. per sec.; $v_{1925} = 17.60$ ft. per sec.; $v_{1950} = 2.12$ ft. per sec.

At this point it is necessary to solve Equation 8 with respect to s, which gives

$$s = \frac{v_1^2 - v_2^2}{2g\left(\sin a + \frac{\cos a}{100}\right)} \qquad (9)$$

Then, making $v_2 = 0$, we find, for the distance in which the car will be brought to rest, on this 18.4 per cent. grade, $s = 0.37$ ft., or Sta. 19 + 50.37.

EXAMINATION QUESTIONS

British Columbia Examination, Third Class, Dec. 17, 1918

(Selected Questions)

Ques.—Describe the various instruments which you, as a fireboss, would use to determine the condition of the mine atmosphere, the quantity of ventilation, and general condition in the air-courses.

Ans.—The temperature of the mine atmosphere is ascertained by means of a good thermometer, similar, in all respects, to the common house thermometer. The humidity of the mine air is calculated from the difference of readings of a wet- and dry-bulb thermometer. This instrument is called a hygrometer. The drier the atmosphere, the more rapid the evaporation of water from the wet bulb and the greater the difference of the readings of the two bulbs, which shows an increased humidity of the air.

The quantity of air in circulation is measured by an anemometer. This instrument consists of a vane having inclined blades and mounted in a suitable frame equipped with dials that mark the number of revolutions made by the vane, each revolution corresponding to 1 ft. of air-travel. A watch for determining the time the instrument is exposed and a tape for measuring the size of the air passage are necessary to calculate the volume of air in circulation.

The water gage, consisting of a U-shaped glass tube mounted on a suitable base is used to determine the difference in pressure between two airways. The greater pressure on the intake airway causes the water to fall in one arm of the tube and rise in the other, the difference in the water levels indicating the pressure producing the circulation. Each inch of the water column corresponds to 5.2 lb. per sq.ft. of pressure.

The barometer is used to determine the amount of atmospheric pressure, which indirectly affects the mine atmosphere by permitting the expansion of gases from the waste and void places in the mine. A decrease of atmospheric pressure indicated by a falling barometer gives warning of an increased gaseous condition of the mine air. The barometer consists of a glass tube closed at one end. The tube is filled with mercury and inverted, the open end being submerged in a vessel of mercury. The pressure of the atmosphere on the surface of the liquid in the basin supports the mercury column in the tube. The mercury column rises and falls as the atmospheric pressure increases or decreases.

Ques.—Describe some system of working a coal seam with which you are acquainted, giving sketches if necessary.

Ans.—The simplest and most effective way of extracting coal from a seam is the method known as the longwall system of mining, whenever this system can be applied successfully. In longwall mining, all of the coal is taken out as the working face is advanced. A solid pillar of coal may or may not be left around the shaft bottom when the work is started. The development proceeds equally in all directions and the working face is approximately a circle or an arc of a circle. As the coal is taken out, the roof settles gradually and uniformly on the waste, which is built up as solid packwalls, a short distance back from the working face. The area at the face is supported temporarily on timbers, which are drawn and reset as the face is advanced. No powder is required for blasting, but the coal after being undermined is broken down by the pressure of the roof. The success of the longwall system depends chiefly on maintaining a uniformly traveling weight on the coal.

Ques.—Describe, in detail, how you would remove a body of gas from a pair of rise headings.

Ans.—First, withdraw all the men working on the return of these headings. Then, start by increasing the quantity of air ventilating the headings and watch the effect. Use only safety lamps of approved type, and make frequent tests to observe what progress is being made in moving the gas. It may be necessary to start a brattice from the mouth of the intake on the gangway and extend it gradually up the rise, allowing the gas-charged air to return behind the brattice. By this means, the gas is gradually removed from the first heading, up to the last open crosscut. When this is reached, the return should be made to pass out through the crosscut, the main line of brattice being extended to the face of the first heading until the gas is completely removed, after which a similar method must be employed by extending a brattice from the last open crosscut to the face of the second heading, until that gas has been removed. It is frequently difficult to remove gas from the face of rise headings, if the gas is warmer and lighter than the mine air.

Ques.—Describe the various means, appliances and fixtures necessary to properly conduct the air current to the various parts of the mine.

Ans.—In conducting an air current throughout a mine, there are required doors, stoppings, air bridges, either overcasts or undercasts, and brattices. Doors mounted in substantial frames set in the airways are made to open against the air current, so that the pressure of the air will keep them closed. A door must be set with sufficient fall to prevent its standing open when not blocked. A stopping is a wall or partition built in a crosscut or passage so as to close the opening to the circulation of air. An air bridge may be either an overcast built above a roadway, or an undercast built in the floor, the purpose being to conduct an air current across the roadway without interfering with the air passing on the road. Overcasts are much preferred to undercasts, as they are less liable to be blocked by an accumulation of water or blackdamp. The term "brattice" is sometimes applied to a wooden stopping, but more commonly refers to a partition of canvas or wood extended along the rib of an airway or other passage to conduct the air to the face. At times, flexible tubes of canvas are used for this purpose.

What Happened in 1918

[Unless otherwise indicated, the bracketed figures in the text refer to pages in the last two volumes and the present volume of *Coal Age* and should the reader desire further information he can obtain it by reference to the pages indicated.]

January

Jan. 1—Mine workers of the Carterville Big Muddy Co. at Cambria, Ill., work on New Year's Day, giving their wages and the company giving its profit to the American Red Cross [XIII, 164].

Jan. 5—Judge Robert S. Lovett, Director of Priority, declares that the "tag system" of giving priority to every car tagged by a Government official, however competent, was cause of car shortage [XIII, 62].

Jan. 10—To save fuel, manufacturers of boxboard agree to close down from 7 A.M. on Saturdays till 7 A.M. on the following Monday.

Jan. 12—Alabama operators ordered to accept Fuel Administration's decision [XIII, 152]—Mine explosion at Minnie Pit of Podmore Hall Colliery, Halmerend, South Staffordshire, England, of the Midland Coal, Coke and Iron Co., Ltd., in which about 160 men lost their lives [*Colliery Guardian,* XCV, 134, 383].

Jan. 14—Francis S. Peabody, Chairman of Committee on Coal Production, testifies before Senate Investigating Committee [XIII, 146]—State Fuel Administrators are given power to divert coal and coke where such diversion is necessary for the assistance of coal-using industry [XIII, 202]—Captain of the Birchenwood Colliery No. 1 rescue team loses his life in rescue work, the reducing valve not being rightly adjusted [*Colliery Guardian,* CXV, 383].—Senate passes Walsh-Pittman coal and oil-lands leasing bill for the general leasing of coal, oil and gas, and sodium lands.

Jan. 15—United Mine Workers Biennial Convention assembles at Indianapolis, Ind. [XIII, 153].

Jan. 17—Referee in bankruptcy orders sale of 12,000 acres of land of J. V. Thompson to H. C. Frick Coke Co. for $500 an acre [XIII, 216]—Francis S. Peabody testifies before the Senate Investigating Committee urging the necessity for clean coal, the need for the zoning of the coal industry and suggesting a price for coal based on coal thickness [XIII, 201].

Jan. 18—All industries east of Mississippi closed down for workless days [XIII, 163, 200, 293, 336]—Garfield adds long list of firms exempted from the workless days order.

Jan. 21—Interstate Commerce Commission upholds the refusal, under certain conditions, of the Baltimore & Ohio R.R. to supply coal cars to wagon mines [XIII, 201]—United Mine Workers of America approve the Washington Agreement [XIII, 248]—First "workless Monday."

Jan. 23—Explosion at Allan shaft, Stellarton, Pictou County, Nova Scotia, 86 lives being lost [XIII, 252].

Jan. 24—J. D. A. Morrow appointed commissioner with the title of Manager of Apportionment and Distribution for the zoning of all fuel except petroleum [XIII, 290]—Anthracite operators pool all coal at New York City.—The Fuel Administration reduces the prices for run-of-mine coal and prepared sizes produced in the Deerfield or Palmyra fields and the Massillon and Jackson fields in Ohio, 5c. per ton. The price of screenings is raised 45c. [XIII, 251].

Jan. 25—United States Fuel Administrator announces his plan for regulating coal distribution [XIII, 250].

Jan. 26—United Mine Workers of America conclude their biennial session at Indianapolis after advocating earlier in the day that the Interstate Joint Conference be widened to include representatives of other districts than Illinois, Indiana, Ohio and western Pennsylvania [XIII, 243]—Fuel Administrator forbids all unusual hours of labor introduced to evade the law relating to workless day provisions.

Jan. 29—Alabama operators agree to comply with the terms of the agreement proposed by the Fuel Administration through Rembrandt Peale and declare they will not recognize the union but will increase wages if necessary [XIII, 294].

February

Feb. 1—General committee of anthracite operators formed to regulate anthracite industry [XIII, 283, 296].

Feb. 4—Dominion Coal Co. makes an agreement with its men [XIII, 381].

Feb. 5—Order in Council passed by Canadian cabinet suspending operation of all manufacturing plants in Canada Feb. 9-11, closing country clubs during February and March and theaters on Mondays from Feb. 18 to Mar. 25.—J. E. Roderick, chief of Pennsylvania Department of Mines, dies [XIII, 308].

Feb. 6—A. C. Campbell and Tudor Williams, fuel administrators in Luzerne and Lackawanna Counties, order the operators in the anthracite region to prepare their coal, as in former days, with breakers and washeries [XIII, 341, 383, 391, 435].

Feb. 7—Members of the mine-cave committee of the Civic Bureau of the Scranton Board of Trade meet with railroad presidents and heads of coal companies in New York City.

Feb. 8—War Department refuses request of Fuel Administration to exempt mine workers.—Fuel Administrator lifts Monday-closing order from North Carolina, Tennessee, South Carolina, Georgia, Florida, Alabama, Mississippi and Louisiana and gives power to state fuel administrators to withhold coal as well as to divert it.—Dr. H. A. Garfield, United States Fuel Administrator, refuses to Alabama the increase of 45c. per ton in the price of coal granted in other regions.

Feb. 10—Changes in demurrage rules come into effect [XIII, 293].

Feb. 11—L. A. Snead, in charge of apportionment and distribution, is appointed assistant to the United States Fuel Administrator with duties similar to those in the office he vacates.

Feb. 12—Tipple No. 5 of the Jackson Hill Coal and Coke Co. is burned in a fire believed to be incendiary [XIII, 391, 436]—Seward E. Button becomes chief of Department of Mines of the State of Pennsylvania [XIII, 342].

Feb. 13—Fuel Administration announces that as the coal situation has improved the fuel restrictions on Mondays will hereafter be removed [XIII, 336].

Feb. 14—Fuel Administrators of New England declare that under powers delegated to them by the National Fuel Administrator next Monday will continue as a holiday in New England except perhaps in New Hampshire. (New Hampshire was later included.)—Big strike commences in the Alabama field at mines of Tennessee Coal, Iron and Railroad Co., and on Feb. 15 extends to Republic Iron and Steel Co. [XIII, 308].

Feb. 15—Judge Strauss, of Luzerne County, Pennsylvania, reverses decision of Workmen's Compensation Board of that state, the judge declaring that the negligent act of an employee does not defeat his right of compensation [XIII, 391]—Smithing coal put at same price as prepared sizes of bituminous coal.

Feb. 17—Ten members of the National Board of Labor named [XIII, 424].

Feb. 18—Coke prices revised by Fuel Administration in certain coke districts of Georgia, Alabama, West Virginia and Oklahoma.—Fuel Administration orders that prices shall be the same for the same kind of coal whether sold by operator or jobber.

Feb. 18-21—New York meeting of American Institute of Mining Engineers.

Feb. 20—Texas and Montana notify the Fuel Administration that they will take care of their own fuel needs during the war. Anthracite is barred entirely in Montana.—The Fuel Administration classifies coal consumers into four groups with priority in coal delivery in accordance with their importance.

Feb. 21—Fuel Administration fixes price of diverted coal [XIII, 378]—Elias Phillips, mine inspector at DuBois, Penn., dies suddenly [XIII, 436].

Feb. 22—By an explosion of 28 cases of powder at the Royal colliery at Virden 4 men were killed [XIII, 436, 476]—Col. Reese A. Phillips, former general manager, Delaware, Lackawanna & Western R.R. Co., Coal Department, dies at Scranton, Penn. [XIII, 436]—George W. Theiss, president, Theiss-Bygate Co., coal operators of Pittsburgh, Penn., former vice-president of the Monongahela River Consolidated Coal and Coke Co., dies of a stroke [XIII, 436].

Feb. 23—Fuel Administrators of Maine, Rhode Island, New Hampshire, Vermont, Connecticut and Massachusetts have decided to suspend "heatless Monday" under the United States Fuel Administration order of Jan. 17.—A. W. Calloway, of the Davis Coal and Coke Co. and the Terminal Railroad Coal Co., is appointed Director of Bituminous Coal Distribution [XIII, 423]—Four shotfirers are killed in an explosion at the mines of the Citizens Coal Co., at Springfield [XIII, 436, 476, 565].

Feb. 26—The Fuel Administration demands greater coal conservation [XIII, 424]—Senator Reed attacks the Fuel Administration in the Senate.

Feb. 27—Frank P. Walsh chosen by American Federation of Labor to serve on the National Board of Labor.—Independent Union of Miners of America organized.

Feb. 28—Fuel Administration orders that where cannel and bituminous coal is mixed the Government price for bituminous shall govern [XIII, 462].

March

Mar. 1—Joint committee appointed by Government officials, eastern railroad representatives and mine operators of Pennsylvania, Maryland and West Virginia to apportion cars to meet the railroad-fuel demand [XIII, 461].

Mar. 2—Bill introduced by government of British Columbia for the establishment of an 8-hr. day, bank to bank.

Mar. 4—Public Service Commission holds a hearing relative to the request of A. H. Wiggin, state fuel administrator, that all private power plants in the city of New York be closed down and power requirements supplied by public-service corporations—Coroner's jury brings in verdict to the effect that Stellarton explosion of Jan. 23 was probably caused by act of an alien enemy.

Mar. 6—Priority given to coal by order of Jan. 17 is removed in all states east of the Mississippi except Pennsylvania, Maryland, West Virginia, Ohio and eastern Kentucky [XIII, 512]—Priority is given to New York Central and Hudson R.R. Co. railroad coal over all other coal contracted for.

Mar. 8—Fuel Administration makes regulations for retailing [XIII, 510].

Mar. 9—The Fuel Administration announces that the prices of anthracite will be reduced 30c. per ton from Apr. 1 to Sept. 1 instead of the usual reduction of 50c. in April, 40c. in May and so on till August when only 10c. is usually deducted from the winter circular. It also announces a system of inspection. Summer reductions in Colorado will apply only to prepared sizes on both domestic and steam coal. It shall not apply to lignite.

Mar. 10—British government announces that on Mar. 21 it will proceed to the enlistment of 50,000 miners.

Mar. 21—Several orders dating back to the order of Jan. 30, 1915, relating to the freight rates on anthracite are vacated by the Interstate Commerce Commission and an increase in rate not to exceed 15c. per long ton is added to the freight rate on anthracite [XIII, 633].

Mar. 16—Rules and regulations governing the distribution of coal and coke by persons, firms, corporations and associations subject to license are formulated by the Fuel Administration.

Mar. 20—Manufacturers of box board, who reduced their fuel consumption by running 5 days a week resume their full schedule.

Mar. 22—The Fuel Administration announces new price classification for the entire state of Illinois and for large coal fields in Ohio, Pennsylvania, Virginia and West Virginia.

Mar. 28—New prices are named for Washington, Oklahoma and Arkansas mines [XIII, 632].

Mar. 29—Companies and individuals using special means for eliminating impurities from their coal will be permitted to add 20c. to the Government price at the mine [XIII, 633].

Mar. 30—United States Fuel Administration advises the public to store coal or otherwise there will be a shortage next winter [XIII, 632].

April

Apr. 1—United States Fuel Administration zoning order comes into operation [XIII, 547]—United States Fuel Administration begins the licensing of jobbers [XIII, 546]—State of Indiana goes "bone dry."

Apr. 4—Use of domestic sizes of anthracite for steam-raising purposes condemned by the United States Fuel Administration [XIII, 698]—Price of coke raised 5 per cent. when manufactured east of the Mississippi River and sold west of the Rocky Mountains [XIII, 698]—Fuel Administration orders that the term "foundry coke" shall cover only coke selected for foundry use according to the usual practice—Charles M. Means appointed manager of inspection division, United States Fuel Administration [XIII, 699]—Judge Strauss, of Pennsylvania, rules, in the Joseph Zadwick case, that the corroboration of a second party is not needed to establish the right to workmen's compensation, when a workman dies as the result of a strain received in an isolated part of the mines [XIII, 714].

Apr. 5—R. P. Prager is lynched as an alien spy by mine workers at Collinsville, Ill., [XIII, 704, 705 and 842]—Big strike commences in the Dombrowa coal fields of eastern Russia.

Apr. 6—Central Pennsylvania mine workers decide to put off their threatened strike [XIII, 704]—Third Liberty Loan is offered for sale.

Apr. 9—Wagon mines forbidden to add cost of hauling to Government price when coal is loaded in open-top cars except where coal is bought by a railroad for its own use—Strike commences at Lethbridge, Alta. [XIII, 749]—President creates a National War Labor Board composed of the same members as composed the commission which advocated the formation of the board—Dr. Garfield demands that the price of coal paid by railroads shall be the price set by the Government as the fair and maximum price at the mines.

Apr. 10—Order of Administration requires that smokeless coal shall be delivered only to the bunkers of ships and specifies that contracts for smithing coal made before Feb. 14 will be abrogated if the coal delivered is found not to be a true smithing coal and if the coal is not used, or to be exclusively used, for smithing. [XIII, 747].

Apr. 11—Bottle manufacturers, not making food containers, agree to reduce their output 15 per cent.—The Government takes control of 63 coastwise vessels which added to the fleet owned by the railroads, which are also federally controlled, makes 111 coastwise vessels under Government control, having a rated capacity of 400,000 tons.

Apr. 12—Explosion in the Shoal Creek mine, Panama, Ill., possibly caused by alien enemies [XIII, 749].

Apr. 13—Zone system modified so as to forbid the Pennsylvania R.R. from delivering in Washington or Baltimore, coal produced on the Pennsylvania R.R., the Monongahela R.R. and the Huntington & Broad Top Mountain R. R., and their short line connections in Pennsylvania, West Virginia and Maryland [XIII, 746]—The International Board of the United Mine Workers of America protests against the frequent changes in coal prices, declaring it a large cause of the irregular work at the mines [XIII, 748].

Apr. 16—Strike commences in Georges Creek and Upper Potomac regions, laying 6000 men idle [XIII, 748 and 796]—Wage increase of 50c. per day granted by the Western Fuel Co., British Columbia, to some 1500 employees [XIII, 749]—Senate and House adopt conference report on "Sabotage Bill," which prescribes imprisonment penalties for interfering with war industry; but the punishment provided for strikers is eliminated.

Apr. 17—United States Fuel Administration announces that the Tennessee Coal, Iron and Railroad Co. will submit to the conditions of the Peale contract in Alabama [XIII, 842]—Strike in Georges Creek region comes to an end [XIII, 748 and 796].

Apr. 21—New wages scale signed for Alabama region [XIII, 797].

Apr. 22—"Lightless Night" order suspended till Sept. 1—Delegates from District No. 2 (central Pennsylvania) meet at Dubois, Penn., and decide against a strike and in favor of an investigation of wages by the United States Fuel Administration [XIII, 796].

Apr. 23—Hitchman Coal and Coke Co. decides to withdraw its action against the United Mine Workers of America which related to the enforcement of so-called "ironclad" contracts with working men in its employ [XIII, 840]—Lehigh Coal and Navigation Co. places girls as timekeepers, weigh-scale tenders, switch tenders, etc. [XIII, 841].

Apr. 24—Commercial florists and enameled ware manufacturers agree to reduce fuel consumption 50 per cent.—Joint conference held at Bridgeport, Ohio, relative to a new sale for No. 8-A seam [XIII, 840].

Apr. 25—Contract signed for No. 8-A seam [XIII, 840]—Men working at No. 11 mine of the Old Ben Coal Corporation are ordered back to work under pain of arrest under charges of conspiracy [XIII, 841].

Apr. 26—Meeting of West Virginia coal operators at Huntington to form state operators' association [XIII, 807]—Four collieries of the Nova Scotia Steel and Coal Co. are laid idle by a "holiday" of indefinite length, a holiday being taken because the mine workers are forbidden by law to strike.

Apr. 27—New zoning arrangements made in regard to shipments in box and stock cars and to the shipment of smithing coal [XIII, 835]—S. E. Button, chief of the Department of Mines of Pennsylvania, agrees to issue orders against the employment of girls in and around anthracite mines [XIII, 841]—Meeting of would-be seceders from the union [XIII, 796]—Extensive modifications are made in the zoning regulations.

Apr. 29—The United States Fuel Administration increases price of coke 60c. per short ton where the coke is for export to foreign countries or for transport to a possession or dependency of the United States. The 5 per cent. on coke shipped across the Rocky Mountains may be added to 60c. under this order [XIII, 837].

May

May 1—The 45c. allowance is conceded to the coal operators of Alabama—The Department of Mines of Pennsylvania declares its intention to enforce the law prohibiting women from doing anything but clerical labor about the mines [XIII, 841, 859, 886]—A cave-in at the White Coal Co., Pittston, Penn., destroys 20 houses and kills one man and injures another [XIII, 889]—Parrish Colliery breaker, now belonging to the Lehigh and Wilkes-Barre Coal Co., falls but without casualties [XIII, 889]—New concrete breaker is started by Delaware, Lackawanna & Western R.R., Coal Department, near Storr's breaker, Dickson City, Pennsylvania [XIII, 946].

May 2—Railroad Administration announces that it has let contracts for the construction of 100,000 freight cars—Special convention of mine workers is held at Birmingham, Ala., to consider the recent wage increase tentatively accepted by the union officials for the mine workers in that state.

May 3—Special orders providing for the diversion of coal to New England, issued during the critical period of last winter, are revoked by the Fuel Administration [XIII, 882].

May 4—First issue of "Saward's Journal," a coal trade weekly edited by Frederick W. Saward, former editor of the "Coal Trade Journal"—End of subscription period for Third Liberty Loan—Collision of cages in Loomis shaft of Delaware, Lackawanna & Western R.R., Coal Department [XIII, 898].

May 7—Order announced penalizing the New York and Philadelphia Coal and Coke Co. for providing low-grade quality of coal for the bunkering of a Belgium relief steamship.

May 8—The shipment of coke produced in the New England States to points outside is forbidden. No coke other than petroleum coke and crushed coke for domestic purposes may be shipped into the New England States from Maryland, New Jersey, New York, Pennsylvania and West Virginia [XIII, 933]—Fuel Administration makes preliminary steps in fuel conservation by appointing Thomas R. Brown, of Pittsburgh, Penn., to classify and rate plants as to their fuel efficiency [XIII, 932].

May 9—The Fuel Administrator authorizes the employment of fuel inspectors for anthracite coal—George T. Watson announces that the Consolidation Coal Co. will put in force an equivalent of the Colorado Industrial Plan [XIII, 934, 935, 976, 977]—All the mines of the Broad Top-Huntingdon field of central Pennsylvania but one are on this date found to be on strike [XIII, 934, 976, 1022].

May 14—Manager and a mine blacksmith are killed and three men injured by the explosion of a powder magazine at the Oliphant-Munson Collieries, Coal Spur, Alberta [XIII, 987].

May 15—Meeting of operators of the Central West Virginia Operators' Association with a representative of the Fuel Administration. The association agrees on behalf of its members to put the Colorado Industrial Plan into operation [XIII, 976, 977]—New scale wages goes into operation in Alabama [XIII, 797].

May 18—Decision of Judge Henry in Dauphin County court in favor of three miners who had been docked for dirty coal. Susquehanna Coal Co. directed to pay them $350 [XIII, 978].

May 20—Announcement is made that the railroads will spend about a billion dollars this year for additions, betterments and equipment, said to be approximately three times as much as in any of the last three years [XIII, 1024, 1025]—Fire at gasoline fan in the mine of the Mill Creek Cannel Coal Co., at Villa, near Charleston, W. Va., smothers 13 men and does much damage [XIII, 987, 1033, 1106].

May 21—National Retail Coal Merchants' Association holds its first annual convention at Atlantic City, N. J. [XIII, 986, 987].

May 22—James Brothers' colliery near Pottsville, Penn., is closed down for shipment of dirty coal [XIII, 1033].

May 23—The Fuel Administration requires that permission be obtained before opening a new mine and announces that it will require proof that the new mines will not secure laborers for opening and development from other mines and will not add to the difficulties of the Railroad Administration [XIII, 1021].

May 25—Price of all bituminous coal reduced 10c. per ton, it being announced that the President has ordered the railroads to pay the Government price for coal [XIII, 571, 779, 839, 885, 975, 1020, 1025].

May 27—Freight rates on coal and other shipments raised roughly 25 per cent. by order of Director of Railroads, McAdoo and the Interstate Commerce

Commission. Passenger rates are also increased to 3c. a mile. Railroad gross income should be increased $900,000,000 a year by the new schedules [XIII, 932, 1020, 1021].

May 28—National Coal Association meets for its two-day session, and before it adjourns votes for incorporation [XIII, 933]—John P. White is appointed a representative of the Fuel Administration on the Labor Policy Board [XIII, 1025].

May 29—Fuel Administration prohibits use of coal or oil fuel after June 11 for private yachts.

May 31—James M. Orr, charged with having secured an excessive price for coal, is fined $5000.

June

June 1—Regulations enforcing the production of clean coal comes into effect [XIII, 1068].

June 3—"Coal Week" (lasting till June 8) commences. All purchasers of coal are requested to place orders for all coal they will need prior to Apr. 1, 1919 [XIII, 973, 987]—Mt. Jessup colliery closed down by Fuel Administrator for shipment of dirty coal [XIII, 1083].

June 4—Meeting of mine workers' delegates in the Huntingdon and Broad Top region vote in favor of returning to work pending arbitration [XIII, 1071].

June 5—Operators' Association formed in the new Elkhorn fields, Letcher County, Kentucky, at a meeting held at Whitesburg—Fuel Administrator issues estimates of bituminous coal likely to be needed from Apr. 1, 1918, to Apr. 1, 1919, at 634,594,000 short tons, or 79,866,000 tons more than produced in 1917. This will be an increase of 14.4 per cent. over last year's production [XIII, 1116].

June 7—Production Bureau of United States Fuel Administration is inaugurated, with James B. Neale, anthracite advisor to the Fuel Administrator, as director [XIII, 1162].

June 10—New freight rates under order of May 25 come into effect—United States Fuel Administrator states that the automobile factories will only be allowed 25 per cent. of the fuel necessary to maintain their former production [XIII, 1162].

June 12—Director of Railroads amends order of May 25 by which intrastate rates are placed at the same level as interstate rates [XIII, 1161].

June 13—United States Fuel Administration gives list of precedences in coal distribution [XIII, 1161].

June 14—Fuel Administration of New Jersey removes 56 tons of coal from summer home of John F. Dryden, president of the Prudential Insurance Co. This is the first excessive stock of domestic coal reduced by Government action.

June 17—"Clean-coal" Conference at Kansas City attended by operators, labor leaders and coal inspectors of Oklahoma, Kansas, Missouri and Iowa [XIV, 23]—Cave-in kills three men at Short Mountain colliery, a Susquehanna Collieries Co. operation near Lykens, Penn. [XIV, 23].

June 19—J. P. O'Connor, doing business as the Penn Fuel Co., is deprived of his license as a coal distributor, having sold high-volatile coal as bunker fuel.

June 20—Notice is served on the Tidewater Coal Exchange to dump coal promptly as received and not hold it for foreign bunkering so as to receive the higher price provided for such coal—Short Mountain colliery closes for two days while three men are buried [XIV, 23, 24].

June 21—United States Fuel Administration declares that "Government prices" are maximum prices and that coal may be sold at lower prices to railroad and other customers at the pleasure of the operators.

June 25—James H. Hoover, of McClellandtown, Penn., is made to pay $2500 to American Red Cross for having violated the Fuel Administrator's orders in regard to the shipment of coke and having neglected to make reports as demanded by the Fuel Administration—Freight rates are increased in accord with General Order No. 28, dated May 25, 1918 [XIII, 1020, 1021]—Dr. James Douglas, of Phelps-Dodge & Co., Inc., and of the Stag Canon Fuel Co., dies at Spuyten Duyvil, N. Y. [XIII, 1217].

June 26—Henderson W. Knott appointed to take charge of engineers and inspectors investigating the power plants of the country and making recommendations relative to fuel economy—Coal operators of central Pennsylvania meet in Washington and condemn the giving of bonuses and like wage inducements [XIV, 24].

June 27—Wagon Mine Owners' Association formed at Pittsburgh.

June 28—J. M. Roan is appointed field manager of the inspection section of the United States Fuel Administration [XIV, 21].

June 29—Report of Federal Trade Commission condemning profiteering, the price of coal being quoted as an instance [XIV, 21, 22].

July

July 1—John S. Wentz, anthracite operator, dies at Philadelphia [84].

July 2—Henry F. Shoemaker, Ohio operator, dies in New York City—The Fuel Administration adds 25 inspectors to its staff to watch the preparation of bunker coal [XIV, 22].

July 3—Viscount Rhondda, coal operator, formerly David A. Thomas British Food Controller, dies [XIV, 66]—Fuel Administration prohibits the distribution of gas coal from docks on Lake Michigan or Lake Superior without permission, except to persons engaged in the manufacture of gas or in the operation of byproduct plants—The Fuel Administration reduces coal supply of breweries 50 per cent. [XIV, 67].

July 4—Jewell Ridge Coal Corporation and mine workers donate to American Red Cross all the coal mined on this day [XIV, 70]—Supply of cars to the Huntingdon and Broad Top R.R. is reduced 50 per cent.

July 5—Fuel Administration defines "modified mine run" and prescribes prices [XIV, 67]—Inquiry by Board into the operation of high-cost mines in central Pennsylvania.

July 6—Anthracite Tridistrict Board asks for a higher wage scale to meet increased cost of living [XIV, 79]—Agreement to compensate owners of undermined and wrecked buildings is made in Wilkes-Barre, Penn.—Department of Labor refuses to permit the importation of Mexican labor to mines in New Mexico [XIV, 70]—Fuel Administration orders that the coal furnished to domestic users shall not exceed quantity necessary to heat every room up to 68 deg. Fahr. [XIV, 68].

July 7—The War Labor Policies Board announces the establishment of Community Labor Boards to mobilize labor [XIV, 70, 71].

July 8—Department of Labor limits work of United States Employment Service to manufacturers of war material employing over 100 workers [XIV, 71]—Anthracite Conciliation Board directs that in case of the funeral of the victim of a mine accident the company owning the mine shall pay an additional $150 to the compensation provided by the compensation law if no men lay idle on that day [XIV, 181, 227]—Furnace Run tipple and retarding conveyor near Kittanning, Penn., burned down [XIV, 148]—Battery of 80 Koppers byproduct ovens charged for the first time by Bethlehem Steel Co., Steelton, Penn. [XIV, 193].

July 10—Thirteen men burned in an explosion of gas at the Lackawanna colliery of the Delaware and Hudson Co. [XIV, 148]—Preferential supply of coal cars to mines producing railroad fuel is discontinued—U. S. Fuel Administration announces that brewers can only count on receiving enough coal to complete the manufacture of beer from materials now in process of manufacture [XIV, 134].

July 11—A. H. Smith, Regional Director of Railroads, issues order to speed railroad coal cars [XIV, 133].

July 12—The National Coal Association with a membership producing annually 400,000 tons of bituminous coal declares in favor of immediate prohibition [XIV, 136]—James B. Neale urges coal operators at Fairmont, W. Va., to spend their time at the mines speeding up production [XIV, 229]—Organization meeting of Northern West Virginia Coal Operators' Association held at Fairmont [XIV, 147].

July 13—Fuel Administration prescribes that country clubs may use wood or peat if railroad services are not utilized [XIV, 133]—Production of bituminous coal in the week just ended reaches 13,243,000 tons, the largest weekly production thus far attained in this or any year [XIV, 180, 185, 196]—Harleigh-Brookwood coal breaker near Hazleton, Penn., is burned down [XIV, 193].

July 16—G. B. Markle Coal Co. puts its new breaker at Oakdale in operation [XIV, 193]—Fanhouse of Lehigh & Wilkes-Barre Coal Co., at Tresckow destroyed by fire [XIV, 193].

July 17—John W. Moore, of Columbus, Ohio, has his distributor's license revoked, and the Elk Coal Co., doing business illegally under his liecnse, is required to refund commissions collected by it upon transactions carried on under the license issued to J. W. Moore [XIV, 178]—Explosion of powder magazine of Black Brothers' Coal Co., Blackfield, Penn., kills one man and injures a dozen others [XIV, 194].

July 18—Coal cut off 70 coal dealers who were remiss in filing weekly reports [XIV, 68, 178].

July 19—Fuel Administration provides that in Michigan, Ohio, Indiana and Illinois, domestic anthracite should be distributed first to those communities within the state which would experience the greatest inconvenience, difficulty and suffering by a failure of the supply expected [XIV, 79]—Fuel Administration formulates orders for a reduction in outdoor lighting [XIV, 178].

July 21—German submarine sinks three coal barges and sets fire to the tug pulling them.

July 22—District draft appeal board at Scranton declares that mine clerks and stenographers are not essential workers [XIV, 239, 227].

July 23—President declares by proclamation that he will assume control of the Cape Cod canal July 25, and directs the Railroad Administration to operate it—Fuel Administration appoints a Bureau of Labor, comprising John P. White and Rembrandt Peale [XIV, 228]—Strikes at 14 mines in Michigan for an increase of 10c. per ton in the rate for coal mining [XIV, 277].

July 24—Coal for lake transportation to be given preference over all coal except railroad coal, byproduct coal and coal for illuminating gas [XIV, 226]—New "Lightless Nights" order of July 19 becomes operative [XIV, 178].

July 25—Fuel Administration sets maximum price of domestic coke [XIV, 226]—Prices are set for coal at all Nova Scotia operations by C. A. Magrath, Fuel Controller of Canada.

July 29—Order in Council in Canada gives railroads the right to file increases in tariff rates of 20 per cent. in transatlantic traffic on Aug. 1, to come into effect Aug. 12, and to remain in force to close of war—Scranton Surface Protective Association declares mine-cave agreement unacceptable—John R. Powell, pioneer "squib" manufacturer, dies at Plymouth, Penn. [XIV, 290].

August

Aug. 1—Mines of the Lehigh Valley Coal Co. at Beaver Meadow are flooded by the rising of Sulphur Creek [XIV, 289]—Increase in wage granted in Alberta coal mines to balance increase in cost of living [XIV, 407, 457].

Aug. 2—Order establishing production committees at all local mines—Fuel Administration provides price for "sized screenings" to take the place of anthracite and to be used in magazine or base-burner stoves.

Aug. 3—Announcement is made that retail coal dealers in Minnesota and South Dakota have refunded $16,000 to their local customers, or where these could not be located to the Red Cross—During the week just ended anthracite production rose to a record figure, 1,750,490 tons.

Aug. 5—United States Fuel Administrator condemns the coal operators for "bidding against each other by payment

of bonuses," threatens where bonuses are paid to assume that the coal price allowed is too high and declares that he will order a lower price in such cases—Delegates from 52 unions in northern anthracite field meet and demand a 25 per cent. increase in wages, time and a half for overtime and double time for Sundays without increase in selling price of coal [XIV, 322].

Aug. 8—Fuel consumption of cement plants restricted to 75 per cent. of average quantity of fuel used in other years.

Aug. 9—President Wilson addresses a proclamation to all engaged in coal mining, urging steady work and the duty of miners to claim and accept exemption under the selective service draft [XIV, 319]—All bars are withdrawn restricting the importation of Mexicans for work at coal mines [XIV, 378].

Aug. 16—President Hayes states that "the only logical solution (of labor conditions in the mining industry) is a substantial flat wage increase to be applied to all classifications of labor [XIV, 365]—Dominion Coal Co. announces bonus to shippers and loaders [XIV, 456].

Aug. 17—Fuel Administration provides that the price of coal delivered into the tenders of engines may be 5c. per ton more than that charged for coal loaded in cars for shipment [XIV, 364].

Aug. 21—United States Fuel Administration limits the amount of coal that may be stored by industrial plants [XIV, 405].

Aug. 22—Meeting of district presidents of United Mine Workers to discuss wage increase urged by President Hayes Aug. 16 [XIV, 365]—Interstate Commerce Commission decides that no additional charge shall be made for freight carried in privately owned cars.

Aug. 23—An order is promulgated by the Fuel Administration removing, except as to breweries, till Sept. 8 the restrictions on the purchase and use of slack and screenings west of the Mississippi River [XIV, 319, 363].

Aug. 24—Fuel Administration announces the beginning of the erection of a "Carbocoal" plant near the junction of the Carolina, Clinchfield & Ohio and the Norfolk & Western railways.

Aug. 25—Strike of men of Nova Scotia Steel and Coal Co. to compel four men to retain union membership on their advancement to position as company officials [XIV, 456, 457].

Aug. 28—Explosion at Burnett mine of Pacific Coast Coal Co., Burnett, Wash., kills 12 men [XIV, 525].

Aug. 31—War Industries Board orders West Penn Power Co. in Pittsburgh district, to give coal mines a full supply of power discriminating in favor of coal companies as against all other industries [XIV, 453].

September

Sept. 2—Flood invades Mary Lee mine of Alabama Co. at Lewisburg, Ala., and drowns two men [XIV, 525].

Sept. 3—Rocky Mountain Mining Institute holds annual meeting in conjunction with American Institute of Mining Engineers; to last till Sept. 6 [XIV, 633-641].

Sept. 4—United States Fuel Administration grants companies the right to charge reasonable switching charges for the diversion of coal wherever such diversion has been ordered by the Fuel Administration to relieve a shortage of fuel—Reclamation of breeze is prohibited by the United States Fuel Administration.

Sept. 6—William G. McAdoo declared that railroads would be able to haul all coal needed [XIV, 556]—Judge Edwin B. Parker, the priorities commissioner of the War Industries Board, formulates lists of the priority of works needing new permits or licenses [XIV, 514].

Sept. 7—Arrangement made by United States Fuel Administration by which the Consolidated Coke Co. of Pittsburgh pays $80,000 to the Steel Company of Canada, of Hamilton, Ont., and to the Thomas Iron Co., of Hokendauqua, Penn., for poor coke delivered to them [XIV, 557].

Sept. 9—National Coal Association denies William G. McAdoo's statesments relative to the ability of the railroads to handle all the coal offered to them [XIV, 556].

Sept. 10—By the fall of a cage in the Protection Island shaft at Nanaimo, B. C., 16 miners lose their lives [XIV, 617].

Sept. 11—W. J. Murray, of the Victor-American Fuel Co., dies at La Jolla, Cal. [XIV, 643].

Sept. 12—Tipple of the Ella Mine of the United Coal Corporation falls on tracks of the Pittsburgh & Lake Erie R.R., carrying down three men, who, nevertheless, escape uninjured [XIV, 618]—Logan Coal Co., of Philadelphia, Penn., is fined $25,000 and money is given to Pennsylvania chapter of the American Red Cross, for selling, as smithing coal, coal that was to be used for other purposes.

Sept. 14—Revision of the regulations governing the storage of coal by consumers of different classes [XIV, 602].

Sept. 15—Big production meeting of West Virginia operators held at White Sulphur Springs, W. Va. [XIV, 605].

Sept. 16—Big strike occurs in the southern anthracite field, the miners demanding that the United States Fuel Administration decide, at once, on the increase of wages to be provided [XIV, 607]—Annual congress of National Safety Council at St. Louis meets; to last till Sept. 20 [XIV, 502-503].

Sept. 19—Southern anthracite strike practically comes to an end [XIV, 607]—Meeting of operators, officials of insurance companies, mine inspectors and officials of the Harrisburg headquarters of the Department of Mines convenes in Harrisburg for readjustment of insurance rates particularly for anthracite mines [XIV, 662].

Sept. 21—The mine workers of District No. 1 of the anthracite region protest against the declaration that they are not patriotic [XIV, 650]—Gladstone and Michel locals vote to return to work till single shift is reëstablished—Union leaders in District 18 suggest that an arrangement be made establishing the single shift for 30 days during which time the single shift might be discussed.

Sept. 23—Explosion at the mine of the Franklin Coal and Coke Co., Royalton, Ill., kills 23 men [XIV, 714].

Sept. 24—Elbert H. Gary, chairman of the board of directors of the United States Steel Corporation, declares in favor of the 8-hour day [XIV, 650].

Sept. 25—Mine workers at Fernie declare that they will call out firemen, pumpmen and fanmen if their demand for a single shift is not conceded without reservation and a promise made to give all men work within 30 days [XIV, 748]—C. A. Magrath, fuel controller of Canada, meets Pictou County, Nova Scotia, mine workers and operators and suggests a 20c. per hour increase in wage to the former, retroactive and good till Jan. 1 [XIV, 748].

Sept. 27—Committee on mechanical labor-saving devices in mining appointed—Pictou County, Nova Scotia, strike comes to an end [XIV, 740]—W. H. Armstrong orders that the Crow's Nest Pass Coal Co. work single shift and proposes that a Royal Commission review the dangers in the mines of the company and report with recommendations [XIV, 748].

Sept. 30—Gladstone local in Fernie, B. C., turns down proposition conceding the single shift but providing for the appointment of Royal Commission to ascertain just what attitude should be taken toward the practice of running a mine more than one shift in 24 hours [XIV, 748].

October

Oct. 3—Wage meeting of Anthracite Conciliation Board with union men and representatives of the Fuel Administration is held at Washington, D. C. [XIV, 703]—Director of Education of the Fuel Administration appointed [XIV, 699].

Oct. 7—Gladstone and Michel mine workers in Calgary field, British Columbia, vote to return to work under provision, of Sept. 27, of Dominion Director of Coal Operations [XIV, 748].

Oct. 9—Conlon mines fall in and cause much damage at Plains in anthracite region of Pennsylvania.

Oct. 12—Fourth Liberty Loan drive commences [XIV, 654, 704, 750]—Announcement is made of the Anthracite Wage Agreement as proposed and accepted by the wage board but not yet made operative [XIV, 701, 703, 705, 789].

Oct. 13—Fourteen bodies are recovered from the north mine of the Franklin Coal and Coke Co., at Royalton, Ill., victims of the fatal explosion of Sept. 28 [XIV, 714, 760].

Oct. 16—United States Fuel Administration authorizes an increase in the reserve stocks of coal held by all classes of consumers except Class 1 east of the Mississippi River.

Oct. 18—Announcement is made that the United States had offered to place at the disposal of the Dutch government 100,000 tons of coal monthly till the end of the war on condition that food be not sent to Germany [XIV, 800, 827, 865].

Oct. 24—New agreement in Vancouver Island, B. C., with wages increased 75c. a day and a sliding scale to adjust wages to cost of living [XIV, 868].

Oct. 26—Dr. H. A. Garfield, United States Fuel Administrator, announces that "the Fuel Administration approaches the winter season well organized with stocks of coal on hand far in excess of the stocks of other years."

Oct. 28—United States Fuel Administration closes 13 small mines producing dirty coal [XIV, 865].

Oct. 31—New anthracite wage scale as forecast Oct. 12 is made operative by the United States Fuel Administration [XIV, 789, 867].

November

Nov. 1—New wage scale in anthracite region comes into effect, having been approved by Dr. Garfield, Oct. 31 [XIV, 789, 829, 867, 908]—Nichol Thompson, Pacific Coast representative of the Fuel Controller of Canada, raises the price of coal in British Columbia 75c. per ton to accord with the wage increase [XIV, 920]—Benjamin L. Flynn, general superintendent, Logan Mining Co., Logan, W. Va., dies of influenza [XIV, 921]—The Fuel Administration declares its intention to commence on Nov. 15 its campaign to provide coal for points in the East, including Pennsylvania, New York, New Jersey and the New England states.

Nov. 2—Fuel Administration announces that 19 more coal mines are closed because their product has been improperly prepared [XIV, 906]—Fuel Administration decides against regulation of opening and closing hours of offices, stores and other mercantile establishments and places of amusement.

Nov. 4—Tipple and boiler house of the Cross Mountain Coal Co., Briceville, Tenn., burned down [XIV, 921].

Nov. 6—New anthracite price schedule agreed upon [XIV, 905].

Nov. 7—Burton L. French introduces into the House of Representatives a bill providing for reconstruction projects [XIV, 952].

Nov. 9—New regulations made regarding "lightless nights"—Regulation made that placing coal in householders' bins shall not permit the retail coal dealer to add more than 75c. to the price.

Nov. 10—Fuel Administration announces that hereafter applications for new railroad switches for use of coal mines shall be filed with local railroad officials and not with the Fuel Administration [XIV, 949]—Fuel Administration announces that New England desires a reduction in its bituminous coal allotment from 30,000,000 tons to 27,300,000 tons [XIV, 950].

Nov. 11—United War Work Campaign Fund Drive starts [XIV, 923]—Armistice is signed by Allies and Germany—Executive Committee of National Retail Coal Merchants' Association favors 2000-lb. ton as standard [XIV, 1053].

Nov. 13—All restrictions on the use of fuel in the production of building materials including brick, cement, lime, hollow tile and lumber are removed.

Nov. 14—Fuel Administration announces that all rules and regulations in force will so remain till the promulgation of the treaty of peace unless revoked by

officers of the Administration [XIV, 949]—Restrictions on clay products and cement set at half those established in the order of Apr. 3 and Aug. 8 respectively [XIV, 950].

Nov. 15—Fuel Administration decides to restrict the operations which it has set on foot to promote the more efficient use of power at mining plants.

Nov. 16—Fuel Administration announces that it will conduct schools of instruction in the cities of Illinois, Indiana and Michigan at which will be explained how bituminous coal can be satisfactorily used as a domestic fuel.

Nov. 17—Fuel Administration rules that smaller sizes of anthracite than pea shall be sold at a price at least 50c. below that established for anthracite of pea size [XIV, 950].

Nov. 19—John P. White, joint director of the Bureau of Labor in the Fuel Administration resigns [XIV, 995]—Fuel Administration announces that certain parts of its work such as the supervision of anthracite and the maintenance of the zoning system cannot be suspended, at least at the present [XIV, 993]—Fuel Administration announces that four more mines have been closed down because of the impurity of the coal produced, making 119 in all.

Nov. 20—United States Fuel Administration announces that instructions have been issued to all camps to release anthracite mine workers [XIV, 993]—"Lightless Nights" are discontinued throughout the country though rulings may still be made by local fuel administrators if in their belief such a regulation is needed.

Nov. 22—Storage limits on bituminous coal are lifted [XIV, 994].

Nov. 25—Arrangements are announced by Fuel Administration under which Pittsburgh consumers are allowed to store their winter's fuel [XIV, 1039]—New prices and regulations made for sale of gas-house coke.

Nov. 26—Fuel Administration speeds up the "Burn Wood" campaign—Embargo of May 5 on coke consigned through New England gateways removed [XIV, 1039].

Nov. 27—Fuel Administration makes changes in consuming zones M-4, M-3, M-2, M-1 and L [XIV, 1083].

Nov. 28—Submarine attacks having ceased coal from two pools is to be permitted to be sold for bunkering purposes—Avondale washery of Delaware, Lackawanna & Western R.R., Coal Department, burns down [XIV, 1052]—Evan D. John, director of the Illinois Department of Mines and Minerals, dies after an illness of five weeks [XIV, 1052].

Nov. 30—Dr. Garfield announces that zoning and coal-price restrictions will probably be removed Dec. 15 [XIV, 1039]—Fire at boiler house of Brownsville Coal Co. does $10,000 worth of damage [XIV, 1094]—New prices made for certain Wise county, Virginia coals, operative Dec. 7—Restrictions removed on use of fuel by florists, window-glass, clay-product and cement manufacturers [XIV, 1039].

December

Dec. 1—District No. 9 (Schuylkill region) of United Mine Workers of America holds its annual convention and raises salaries of its officers 50c. a day from Dec. 1, 1917—Conference of heads of Bureau of Mines and Geological Survey with Fuel Administration at which it is arranged that Conservation Bureau and engineering program looking to development of power near to or at the coal mines shall be turned over to Bureau of Mines and Statistical Bureau shall be taken over by Geological Survey.

Dec. 2—Strike commences in Roaring Creek field of West Virginia [XIV, 1128]—Tipple and chute of Wisconsin Steel Co., Benham, Ky., destroyed by fire [XIV, 1140].

Dec. 3—Strike of 200 men of New River Coal Co. [XIV, 1128].

Dec. 4—Fuel Administration issues order prohibiting an increase of $1.05 in gashouse coke to correspond with rise in the price of anthracite by which the price of gashouse coke was recently regulated [XIV, 1083]—Retail dealers, hospitals, schools, public utilities and government agencies, federal, state and municipal, urged to make their own provision for bituminous-coal supply at once, requisitions of the Fuel Administration for industrial plants being cancelled [XIV, 1083]—Distribution of coke in each state is given to state fuel administrator who is empowered to authorize domestic consumers to use that fuel [XIV, 1083].

Dec. 5—A $50,000 fire at Richard, W. Va., plant of Elkins Coal and Coke Company.

Dec. 7—Convention meets in District No. 1, Wilkes-Barre, Penn., and declares wage scale of Oct. 30 unsatisfactory [XIV, 1127]—Fuel Administration announces that coke may now be reclaimed from coke piles and sold at $5.50 per short ton at the place of recovery—New prices are put in force for such coal mines in Knox and Whitley counties in Kentucky as are operated by members of the Tri-county Blue Gem Coal Operators' Association—New prices become effective at several Virginia mines under orders of Nov. 30 and Dec. 6—Orders of Sept. 19 relative to restrictions on shipment of coal to Canada revoked [XIV, 1083].

Dec. 10—General election of officers, United Mine Workers of America [XIV, 1040, 1127]—Case of Coronado Coal Co. et al against United Mine Workers of America is reviewed by United States Court of Appeals [XIV, 1040, 1128]—R. A. Quin, general manager of Susquehanna Collieries Co., declares it to be the company's intention to reinstate all men on their return from the service of nation [XIV, 1140].

Dec. 11—Mass meeting is held at Charleroi, Penn., at which it is decided to hold a special meeting of delegates from locals to demand a wage increase [XIV, 1127].

Dec. 13—N. S. Schroeder is appointed Director of Bureau of State organizations, vice Evans Woollen, Acting Director.

Dec. 16—Virginia coal prices are codified and coal zones F-1 and F-2 modified. Under latter, coal from all operations in eastern Kentucky along Louisville & Nashville R.R. may be shipped to all points in Indiana located on and east of the Chicago, Indianapolis & Louisville R.R., from Louisville to Michigan City for industrial purposes only, and to all points in the lower peninsula of Michigan without restriction [XIV, 1126].

Dec. 17—Agreement between Northern West Virginia Coal Operators' Association and the United Mine Workers of America, District No. 17, agree on wage scale at Fairmont, W. Va. [XIV, 1170] George B. Markle Coal Co. introduces Mexican laborers into the mines. [XIV, 1170]—Fuel Administration modifies producing zone M-2 and enlarges consuming zone M-2—Logan and Kanawha coal is permitted to go eastward in Virginia and West Virginia on the new line of the Chesapeake & Ohio R.R., including tidewater and terminal points [XIV, 1169].

Dec. 19—Premature shot kills two miners near Providence, Ky. [XIV, 1182].

Dec. 20—Fuel Administration modifies bituminous coal zone P-1 so as to permit all-rail shipment of bituminous coal on the Baltimore & Ohio, the Western Maryland and Pennsylvania to all points in New England; also modifies bituminous coal zone P-2 to permit the shipment of bituminous coal from all districts of Pennsylvania to Baltimore and vicinity, and to the District of Columbia [XV, 22].

Dec. 21—Strike for an early payday at Storrs and Diamond collieries of Delaware, Lackawanna & Western R.R. Co., Coal Department. Last till payday [XV, 24]—Explosion at the Havaco Mine of the New River Pocahontas Consolidated Coal Co., at Havaco, near Welch, W. Va., kills two men. Two rescue men are overcome by afterdamp when masks leak [XV, 35].

Dec. 22—Fuel Administration announces that zone regulations and maximum prices on coal will not be removed before Feb. 1, 1919.

Dec. 23—Wilkes-Barre Coal Co. of New York City requested by Federal Fuel Administrator of State of New York to pay $50 to American Red Cross as penalty for delivering coal without a permit to the customer of another dealer. Paid about Jan. 8, 1919.

Dec. 24—Fuel Administration announces that coal may be sold for export without a permit [XIV, 1169].

Dec. 27—Fuel Administration orders that where anthracite coal is obtainable by-product coke shall be sold at not more than the price charged under the regulations governing the sale of gas coke. This order applies solely to consumers of less than car-load loats and domestic consumers, as did also the gas-coke order.

Dec. 28—Meeting of 125 insurgent delegates in District No. 1, United Mine Workers of America, call on Lewis and Green of the international organization to explain why wage concession of Oct. 30 was not dated Oct. 1 [XV, 52].

Dec. 29—Meeting held in Belleville, Ill., field at which mine workers demand Government ownership and democratic management of the mines [XV, 62].

Successful Stoking of Brazil Coal

By pulverization, it has been possible to use with success, the impure coal of Brazil, under the locomotives of the Government-owned railroads of that country. Twelve locomotives were built and equipped, in the United States, to burn pulverized coal. They were shipped to Brazil early in 1917 and put into fast passenger service. It was the intention to burn the native Brazilian coal, a means of using which in locomotive service had not then been found. On the run of 110 miles for the round trip and several hours standby, 6 metric tons of Brazilian coal were consumed.

If the same amount of United States coal had been used, it would have cost, at $40 per ton, $240. The Brazilian coal cost half as much, and so a saving was made, for the run, of $120. After a service test of six weeks had been made on one of these locomotives, the flue sheet and tubes were found to be absolutely clean though the firebox had not been opened except for the dumping of the ash and slag.

These Brazilian coals ran high in sulphur, the percentage ranging from 4.5 to 6 per cent. However, no difficulties arose from the high sulphur percentage, nor did the sulphur have a deleterious effect on the boiler. These coals have a high percentage of moisture and ash, the proportion of the latter ranging from 22 to 30 per cent. Where possible the moisture was reduced before pulverizing to 3 per cent. and less. On several trips a low grade of Brazilian lignite was successfully burned, although the moisture ran as high as 12 per cent.

COAL AND COKE NEWS

Harrisburg, Penn.

Foreigners, permanently disabled while at work in Pennsylvania, will be paid their full compensation awards in lump sums, so that they may return to their respective countries, where they may, if possible, become self-supporting, according to a decision reached on Jan. 15 by members of the State Workmen's Compensation Board and representatives of employers. During the hearing it developed that many of the permanent disabled claimants have requested their compensation in full, so that they could go to their homes in foreign lands and buy farms or engage in some other business which would insure them a livelihood. The commission and employers decided to coöperate in paying the full awards, the initial payment being sufficient to carry the claimants and family to their foreign homes. On their arrival at their destination, the American Consul or other authorized agent will pay the remainder of the claim. It was announced that in many instances American consular agents have purchased farms for the disabled workers at the request of the latter.

Industrial concerns through the Lehigh Valley are much interested in the Delaware-Lehigh Atlantic coast inland waterway system proposed by the Morrisville (New Jersey) Chamber of Commerce to the United States Railroad Administration. The recommendations include plans for a reconstructed 1000-ton barge canal from Morrisville to Mauch Chunk and to Coalport, the northern terminus of the Lehigh Canal, a mile and half from Mauch Chunk. The total distance 708 miles, and the total lift from tidewater to the end of the Lehigh Canal, piercing the very heart of the anthracite coal region, is 563.5 feet.

Seventy-nine per cent. of the slate quarried and manufactured in the entire country comes from this region. Thirty-six per cent. of all the cement manufactured is taken from this same region, and, what is most important of all, millions of tons of anthracite coal are taken annually from the northern part of this immensely wealthy region.

Uniontown, Penn.

Removal of the fixed price on coal and coke Feb. 1, will have little or no immediate effect, operators believe, upon the local region. Virtually all coke contracts for the first half contain clauses providing for the suspension of the Government price, and demand will not then be sufficient to send the price upward. A reduction in price of spot coke for a short period would not be much of a surprise here. Explanation of the temporary backward trend of the market is found in the fact that a number of blast furnaces have blown out stacks for repairs. Within 60 or 90 days they will again be running at capacity and demanding more coke. The furnaces at present are taking all the Connellsville coke produced, but the market is not brisk. The coal market here has been inactive for two weeks, coal having sold as low as $1.90. That applies particularly to the small operators, a number having been forced out of business.

A gain of 20,000 tons in the coke output was noted in the production report for the week ended Jan. 11, which placed the aggregate output at 576,538 tons coal. Coke shipments were 270,915 tons. Coal shipments dropped off 3000 tons, being 170,415 tons. The region is still running 75,000 tons behind normal production.

Charleston, W. Va.

Market conditions at the outset of the week beginning Jan. 13 in the Kanawha district were such as to cause operators to restrict work at the larger plants to about half time, due to the fact that Western consumers are withholding orders until they are a little more certain as to what the future holds, especially in view of large reserve stocks on hand. Since Kanawha district coal for the most part goes to the West, such a condition tends to reduce the demand in that district and, therefore, Kanawha operators look for no increase in orders for at least another thirty days. A slow market is reflected in the output for the week ending Jan. 11, when 116,800 tons of coal was produced in 3163 working hours. Car shortage caused a loss of only 130 hours and labor shortage 207 hours, while "no market" was responsible for the loss of 1026 hours and mine disability for 197 hours.

Impetus was given production in the New River district during the week ending Jan. 11 and in the following week by the removal of embargoes on tidewater shipments which had been in effect for almost a month, although operators were somewhat apprehensive that there might be further embargoes. Physical conditions, however, were entirely satisfactory, cars being plentiful and the man power sufficient to mine all the coal it was possible to load. It will be fully three months, however, before there will be a return to the normal demand, in the opinion of operators.

Although train crews on the Norfolk & Western Ry. have been reduced as the result of a falling off in coal shipments, there has been an increase in the output of the Pocahontas and Tug River district, which has again reached 300,996 tons as compared with 156,000 tons, reducing the tonnage loss to 85,795 tons, labor shortage constituting the biggest loss—47,702 tons. Only 2448 tons were lost from car shortage. The loss from "no market" amounted to about 20,000 tons. The demand has been rather dull for several weeks so far as the Tug River and Pocahontas fields are concerned, but this condition, it is believed, will not last long. Zone restrictions, however, have and are working a great hardship on the mines of the district, some of which have been shut down entirely.

Market conditions, insofar as the Fairmont district is concerned, are fair and the mines have not had much occasion so far to limit their output. Cars have been unusually plentiful. The supply has run from 1400 to 2400 cars a day. The greater part of the region's product is being shipped to the East, where there appears to be a little better market than there is in the West. The operations in the district have been besieged to dispose of their coal at a sacrifice, but prices, generally speaking, are being maintained.

A slight gain was made in production in the Logan mining district during the week ending Jan. 11 as compared with the previous week, 151,499 tons being produced, the tonnage loss amounting to 135,-921 tons. By far the greatest loss was sustained through "no market", that loss reaching 96,975 tons. Car shortage also caused a considerable loss—22,074 tons.

Birmingham, Ala.

Coal production for the week ending Jan. 11 went to 339,080 tons in Alabama, compared with 250,147 for the week ending Jan. 4 and 109,179 tons for the week ending Dec. 28. Every indication points to an increase for the week ending Jan. 18. Zone and price regulations suspended Feb. 1 by the Government will have little effect here, it is said, as there is a market for every ton of coke or coal produced, and all dealers have orders for weeks ahead. Alabama producers say that they do not apprehend much change in business conditions as a result of the suspension order because all intend to live up to their contracts. The shortage here is not confined to the district, but yards within ten miles of some of the largest mines are unable to get coal in the quantities they demand.

Contracts between operators and miners will be maintained at the present scale until the end of the war, perhaps longer. Commissions for dealers, brokers and others will be taken up in plenty of time before present arrangements are abrogated.

Victoria, B. C.

The securing of an adequate supply of coal at reasonable rates for the City of Prince Rupert, B. C., has been under investigation by the Council of that community. Nicol Thompson, Fuel Controller, was interrogated as to charges, and in his reply stated that it had been arranged when he visited Prince Rupert in October, 1917, that the price of coal should be made by the dealers at their wharf or shed, cost of delivery to be arranged with the purchaser. At that time it was figured that the price would be $10.50 a ton, but since then there had been advances, making the cost at the mines as follows: All coal mines on Vancouver Island, except the Western Fuel Co., $7.20 per gross ton; Canadian Western Fuel Co., $6.45 per gross ton. Mr. Thompson further explained that under the new regulations, while the price at which a dealer might sell was not fixed, his profit was limited to 50c. per net ton over all reasonable overhead charges.

Mayor Gale, of Vancouver, wrote Prince Rupert that the retail price of coal delivered in sacks over the greater part of his city was $10.50 per ton of 2000 lb. He added that Vancouver had the privilege under charter amendments secured two years ago to operate its own coal business, and it has actually supplied all civic and semi-civic buildings at actual cost, although the city has not gone into the coal business in the ordinary way. The Prince Rupert Council finally recommended the establishment of closed coal bunkers operating on a gravity system, in order to eliminate much of the labor now wasted in distribution; that coal be purchased by consumers in bulk as far as possible to avoid the extra 50c. a ton cost for sacking; that a representative of the city be appointed to coöperate with the Provincial Fuel Controller for the regulation of supply and prices in the Northern District; and that Prince Rupert be given power under the Municipal Clauses Act to operate coal yards if it is found in the public interest that such a policy be adopted.

PENNSYLVANIA

Anthracite

Morea—The Morea Colliery of the Mill Creek Coal Co. has been completely electrified. John Creilin is chief electrician at the plant.

Cresson—The Pennsylvania Coal and Coke Corporation has contracted with the Roberts & Schaefer Co. for the installation of a tipple and washery at its Patton mine.

North Pittston—Three men employed at the No. 9 colliery of the Pennsylvania Coal Co. were seriously burned by an explosion of gas on Jan. 14. It is alleged that the men went into the working place contrary to the orders of the fireboss. Fortunately, the quantity of gas that had accumulated was small and no serious damage was done to the mine.

Wilkes-Barre—Charging that coal property is assessed 500 per cent. above its actual value while other classes of real estate in the city is 30 per cent. undervalued, Lehigh Valley Coal Co. attorneys have filed an appeal from the assessed valuation of its property in four wards of the city as fixed for the coming year by the board of revision of taxes and appeals.

Uniontown—Sale of 2225 acres of Greene County coal land, involving a price of $1,335,000, was reported here recently. The tract was purchased by the Cumberland Coal Co. for the United States Steel Corporation, which, with the new tract, now controls 17,000 acres of coal land in the county. The purchase included the holdings of the Cray, Moran and Hibbs tracts; the price paid was $600 an acre.

Uniontown—Development is to be commenced immediately of a 35-acre tract of coal located near Belle Vernon, which was purchased this week by W. H. Wilkey. The property comprises what is known as the Morgan and Beazell tracts, and includes 100 acres. Operation of the mine will be commenced Apr. 1. The coal is especially fitted for byproduct purposes. The consideration was $52,000.

VIRGINIA

Kiser—After a suspension of a few months at the instance of the Government, construction work on the big byproducts plant of the International Coal Products Corporation, at this place, has been resumed and the plant will be rushed to completion. When completed it is estimated that the plant will represent an expenditure

of $3,000,000. Byproducts of coal, much of them for Government use, will be manufactured at this plant.

WEST VIRGINIA

Meadowbrook—The Lambert Run Coal Co. is making rapid progress in the construction of a number of new miners' residences near its properties in this section.

Moundsville—S. Dorsey has recently completed negotiations for the purchase of a large tract of coal properties in the Washington and Clay Districts, near Moundsville, and plans are now in formation for early development work.

Perryville—Numerous improvements have been made by the New Export Coal Co. at its plant at this place, among the most important of such improvements being the construction of a new power house, in addition to 20 new miners' dwellings. The executive in charge of operations is W. F. Mandt.

Huntington—Huntington has been made the headquarters of the newly organized General Coal Co., which has a capital of $50,000 and which will undertake the development of coal lands in the Guyan region. The company was organized by J. L. Brooke, E. A. Spreen, R. S. Quinn, Thomas Quinn and W. J. Quinn.

Mount Hope—The East Gulf Coal Co., recently organized, is planning to commence development work at once on a tract of coal lands comprising approximately 4500 acres, near Mount Hope. It is understood that the company is arranging plans for the development of a townsite to comprise about 150 residences, the erection of tipples and necessary mining machinery for the initial development of two mines. P. M. Snyder is president; L. S. Tully is secretary-treasurer, and P. C. Thomas is manager.

Huntington—Seven thousand acres of coal land in Boone County have been acquired by the Youghiogheny and Ohio Coal Co., a Cleveland concern, from the Crane Real Estate Trust, the amount involved being, it is understood, close to $1,000,000. The property which changed hands represents some of the holdings of the late J. O. Cole and the late Clinton Crane. From what can be learned the company will not undertake the immediate development of the newly acquired land but will in time establish a large plant for the development of its new holdings, where there is much fine standing timber.

KENTUCKY

Chavies—A tipple is to be built in the near future by the Coneva Coal Corporation, which began the mining and shipping of coal recently from its No. 3 mine at this place. The company is now having estimates made on the probable cost of the new tipple.

Lynch—The United States Coal and Coke Co. is planning to commence work at an early date on the installation of a new tipple at its properties. It is understood that the company is planning for increased development operations to bring the daily output to about 400 cars.

Benham—The Wisconsin Steel Co. is considering plans for extensive improvements at its local coal properties, including the construction of new tipples and the installation of coke ovens, to provide for increased capacity. The company is a subsidiary of the International Harvester Co., Chicago, Ill.

Barbourville.—The Horse Creek Coal Co., of Manchester; and the Manchester Coal Co., of the same place, will be able to get out coal in the spring as a result of the completion of the Horse Creek branch line, built by private capital, and connecting with the Cumberland & Manchester R.R. Several other mines have been started and will be ready to ship shortly.

OHIO

Athens—Mine 254 at Jacksonville, belonging to the Collieries Co., and one of the oldest mines in continuous operation in the Hocking field, was put out of commission by a $20,000 fire which destroyed all the machinery. The cause of the fire has not been determined.

Bridgeport—A number of coal mines in the eastern Ohio district are closed down, and others are operating only on part time, according to William Roy, president of Ohio Mine Workers, District No. 2. Shutting off of lake shipments and the closing of the Government pools at Cleveland and other distributing centers are responsible, Mr Roy thinks

ILLINOIS

Toluca—The Jackson-Walker Coal Co., of Kansas City, has finished rebuilding its plant at this place. It is an old property, and the company has put in entirely modern equipment. This company's mines are located at Marceline, Mo., Pittsburg, Kan., Osage City, Kan., and at this place. The output is sold principally to the Santa Fe Ry. The company is now working five mines and controls the output of fifteen more.

Springfield—Citizens' Mine A of the Citizens Coal Co. has reopened after a shutdown of two months, giving employment to more than 200 men. The company expects to operate indefinitely.

The Springfield Consolidated Railway Co. has suspended its service to the Deveraux mine. It is expected that arrangements will be made for the running of special work cars morning and evening.

Carlinville—The Standard Oil mine at Berry, near here, will soon be ready to work, and other large developments owned by the company in this vicinity are being pushed as rapidly as possible. General Manager Maubeck and Major Douglas, chief engineer of the Chicago & Alton R.R., were in consultation recently with Assistant Manager Frank R. Fisher, with a view to facilitating the work.

MISSOURI

Kansas City—A new coal mine by the Palhattan Coal Co. has been opened in Macon County, Missouri. The operation has a capacity of 600 tons a day.

New plant No. 68, in Macon County, which the Central Coke & Coal Co., of Kansas City, is erecting at a cost of $200,000, is now being developed and is producing 100 tons of coal a day. In three months, when all the machinery is installed, it will produce 2000 tons a day. It is one of the largest mines owned by this company.

Foreign News

London, England—The Southport Miners' Federation, which demanded on Wednesday, Jan. 15 that the Government demobilize all miners in the army, also decided by a majority of more than two to one to demand an advance of 30 per cent. over present wages other than war wages.

American Headquarters in Germany—The disorders in Berlin, with the resultant interruption to railway traffic, are threatening to cut off the coal supply of the allied armies of occupation. A commission of American, British and French military officials left on Jan. 10 for the coal fields to investigate conditions. The American army alone uses 25,000 tons a month.

Victoria, B. C.—The Groundhog anthracite coal fields of British Columbia are to be developed, according to responsible mining men. These are situated north of the Hazelton district and contain eleven known commercial seams, aggregating about 68 ft. in thickness. Interest in these measures is held by Sir D. D. Mann and the Lord Rhondda Estate. While active work was suspended during the war, it is asserted that it will be resumed without loss of time.

Medicine Hat, Alta.—At a meeting of the Federation of Labor of the Province of Alberta held at Medicine Hat, Alberta, on Jan. 10, several suggestions affecting the regulation of coal mining in that province were indorsed which, if put in the form of legislation and enforced, will radically alter the present conditions. One provides for the compulsory use of electric safety lamps; another, that mine inspectors shall be elected and be subject to recall; and a third that a 6-hour day shall be granted to all underground workers.

Victoria, B. C.—Considerable interest is taken by coal mine operators of British Columbia in the announcement attributed to local officials of the Canadian Collieries (D), Ltd., that plans are being prepared by the company for the opening of new mines on the island and generally extending operations. On Jan. 6 a meeting of the directors was held at Montreal, when the resignations of Sir William Mackenzie as president and Sir Donald Mann, as a director, were received, their places being taken, respectively, by H. S. Fleming, of No. 1 Broadway, New York, and F. Perry, of Montreal.

Personals

Cary Hymere has been appointed state mine inspector of Indiana under the state industrial board. He is now a deputy state mine inspector. He succeeds Michael Scollard, who resigned a number of months ago.

Lieut. H. H. Johnson is now through with his duties in the United States Army and will resume his service with the Electric Service Supplies Co., of Philadelphia, Penn. Mr. Johnson will represent the company in the Illinois coal field.

Isaac Taylor, of Uniontown, Penn., general manager of the Snowden Coke Co., near Brownsville, Penn., was painfully injured at the Company's operation on Jan. 15, by the haulage rope flying off the sheave wheel and striking him on the leg. Mr. Taylor will be laid up for a week or more.

E. S. McCullough, of Monongahela, Penn., former vice president of the United Mine Workers of America, has been appointed commissioner of the Northern West Virginia Coal Operators' Association. The association represents a tonnage of 20,000,000 tons. Mr. McCullough will make his headquarters at Fairmont, W. Va.

Obituary

James Goldsworthy, for 15 years inside superintendent of the Honey Brook division, Lehigh and Wilkes Barre Coal Co., and for three years in a similar position in the Wyoming division, died at his home in Ashley, due to an attack of pneumonia.

James H. Small, secretary-treasurer of the Central Coal and Iron Co., Central City, Ky., dropped dead of apoplexy on Jan. 13, at the McDowell Hotel. Mr. Small was 49 years of age, and a native of Russellville, Ky. For several years he was with the Adams Express Co., as manager at Owensboro, and later at St. Louis. About ten years ago he went with the coal company, and later secured large interests in mines at Render and Beaver Dam, Kentucky.

John F. Meagher, age 37, general superintendent of coal mines for the Tennessee Coal, Iron and Railroad Co. in the Birmingham District, died at his home in Pratt City after a short illness of influenza followed by pneumonia. He was born in Maryland but moved here with his family during early boyhood. For the past seven years he had been in charge of six of the eight divisions of his company, which embrace twenty mines. He had on many occasions led his crew of helmet men in mine explosions and was loved generally by the miners.

Coming Meetings

New England Dealers' Association will hold its annual meeting March 19 and 20 at Worcester, Mass. Secretary, C. R. Elder, Boston, Mass.

American Wood Preservers' Association will hold its annual meeting Jan. 28-29, 1919, at St. Louis, Mo. Secretary, F. J. Angier, Baltimore, Md.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Rivers and Harbors Congress will hold its fourteenth convention Feb. 5-7 at Washington, D. C. Secretary, S. A. Thompson, Colorado Building, Washington, D. C.

Canadian Mining Institute will hold its annual meeting March 5-7 at the Windsor Hotel, Montreal, Canada. Secretary, H. Mortimer-Lamb, Drummond Building, Montreal, Canada.

American Institute of Mining Engineers will hold its 119th meeting Feb. 17-20, 1919, in the Engineering Societies' Building, New York City. Secretary, Bradley Stoughton, New York City.

American Institute of Electrical Engineers will hold its annual midwinter convention Feb. 19-21 at the Engineering Societies Building, New York City. Secretary, F. L. Hutchinson, New York City.

Trade Catalogs

Copies of the catalogs, booklets and other literature listed below may be obtained free of charge by addressing the manufacturer.

Fairmont Runabout Mine Pump. Fairmont Mining Machinery Co., Fairmont, W. Va. Bulletin No. 13. Pp. 6, 6 x 9 in., illustrated. Explains the features of a portable electric mine pump.

Three-Phase Low Tension Equipment. Delta-Star Electric Co., Chicago, Ill. Bulletin No. 302. Pp. 4, 8 x 10½ in., illustrated. Deals with wiring supports, plugs and receptacles. General information is given of the application of unit type plugs and receptacles of the extra heavy type.

Steelcrete Machine Guards. Expanded Metal Engineering Co., New York, N. Y. Booklet. Pp. 40, 3½ x 6¼ in., illustrated. Describes and illustrates "Steelcrete" machine guards. The booklet will be found extremely valuable to any one who desires to install machine guards.

Sullivan Portable Mine-Car Air Compressors.—Sullivan Machinery Co., Chicago, Ill. Bulletin 75-I. Pp. 8, 6x9 in., illustrated. Describes the Sullivan class "WK-2" air compressors, mounted on a special truck. Are used chiefly in coal mines, where they are found convenient for converting electricity into air power for the operation of drills, coal pick machines in headings, post punchers, cement guns, etc.

Ladew Leather Belting. Edw. R. Ladew Co., Inc., Glen Cove, New York, N. Y. Catalog. Pp. 108, 6 x 9 in., illustrated. A beautifully printed catalog giving the history, standards, methods and policies of the company. It is in effect a treatise on the manufacture and use of leather belting. Belts for all purposes are described, as are also the many different specialties manufactured by the Ladew company. A comprehensive index is a useful feature in the catalog.

Industrial News

Buffalo, N. Y.—Reduced water pumpage in the city of Buffalo during December resulted in a saving of more than 1100 tons of coal at the pumping stations.

Wayland, Ky.—On Feb. 1 the purchasing department of the Elk Horn Coal Corporation will be transferred from this place to Wheelwright, Ky. G. S. Kinzer is purchasing agent.

Bethlehem, Penn.—The Guerber Engineering Co. has changed its title to Bethlehem Fabricators, Inc. The ownership, direction, management and policy of the company are not changed.

Virden, Ill.—The Montour Coal Co. has changed its name to the Pittsburg Coal Co. The company's mine at Virden is known at the North Mine. Arthur Neale will continue as superintendent.

Charleston, W. Va.—In line with recommendations made by Governor Cornwell, the state department of mines will ask the present session of the legislature to provide for the appointment of three additional mine inspectors and an increase of salary for inspectors of 25 per cent. The present rate is $175 per month.

Louisville, Ky.—B. F. Avery & Sons, large plow manufacturers, will be large consumers of coal in the fall, as the company has arranged to increase its plant by one third, having purchased a line of harvesting machinery from the International Harvester Co. and arranged to manufacture it at Louisville instead of Springfield, Ohio.

New York, N. Y.—William McElraevy has been appointed district manager of the Dominion Asbestos and Rubber Corporation of New York. Mr. McElraevy was formerly manager of the New York Branch power plant specialty department of the H. W. Johns-Manville Co., in which capacity he served for nine years and with a very successful record.

Pittsburgh, Penn.—The Draeger Oxygen Apparatus Co. on Jan. 7 changed its name to the "American Atmos Corporation." The charter of the company remains the same, except to the extent that it is authorized to manufacture various forms of breathing apparatus regardless of whether dependent upon oxygen or not. The officers and directors of the company remain the same.

Pittsburgh, Penn.—Members of the Pittsburgh Coal Exchange, at a meeting held on Jan. 11, elected Captain W. B. Rodgers to serve as president, this being the twenty-second consecutive year that he has held that position. Captain J. Trank Tilley was elected secretary for the twenty-eighth time. He was also made vice president, and will serve with the other men elected to that office, W. Harry Brown and A. B. Shepherd. H. O. Stang was elected assistant secretary.

Birmingham, Ala.—The Alabama Coal Operators Association has filed a petition with the Birmingham district freight traffic committee asking that a through rail and water rate from the Birmingham district to Mobile and New Orleans be published. The combination rate, it is understood, is requested in behalf of operators whose mines are contiguous to the Warrior River, and if granted will enable them to take advantage of the cheaper water transportation rates.

New York, N. Y.—The General Briquetting Co., 25 Broad St., is installing its new demonstration and custom briquetting plant at 57th St. and 12th Ave., New York City. Provisions have been made to demonstrate on a commercial scale modern methods of briquetting coal fines, coke breeze and lignite, as well as metal, ores, concentrates and flue dust. The installation includes Belgian roll coal briquetting machinery, complete with masticator for the Dutch oil process, dryers, elevator and conveyor system and power plant. It will commence operations about Feb. 1, 1919. Cost $200,000.

New York, N. Y.—With a view to putting into effect the recommendations contained in the report of the Foreign Trade Committee of the National Coal Association, that an association be formed under the Webb-Pomerene Law, to be known as the American Coal Exporters, Inc., there was a gathering of a few operators at the office of F. W. Wilshire, of the Consolidation Coal Co., of this city, on Jan. 15, at which preliminaries were discussed. Because of the small attendance, however, nothing definite was decided upon, but it is understood another meeting is to be held within a short time.

Morgantown, W. Va.—The coal producers of Morgantown received notice a few days ago that the railroads to which they had been furnishing fuel coal for some time would cancel all contracts for the present, claiming the right under the rules promulgated by the National Fuel Administration to cancel all contracts. Heretofore the railroads have been paying $2.50 a ton for coal, but have notified the dealers that they will not now consider a price above $2. This will serve completely to put the wagon mines out of business, as soon after the signing of the armistice that 75c. a ton extra allowed the wagon mines was taken off the price and the additional cut of 50c. a ton will make a difference of $1.25 a ton.

Carbondale, Ill.—George R. Sheldon, New York, financier, died at a hospital here on Jan. 14 from injuries received in the mine of the Union Fuel Co., at Dowell, 14 miles from here. He was a director of the fuel company, which is a subsidiary of the Union Electric Light and Power Co. of St. Louis, and with twelve other men was making an inspection of the mine. He became separated from the rest and was caught between a moving string of loaded coal cars and a rib of coal. He was also a director of the West Kentucky Coal Co. and was Chairman and Treasurer of the Board of Directors of the North American Co., which owns the Union Electric Light and Power Co. and the United Railways Co. of St. Louis.

Columbus, Ohio—Bids were opened Jan. 6 by the Columbus Board of Purchase for coal for the various departments as follows: 1400 tons of nut, pea and slack for the garbage and refuse departments; 2000 tons for the water-works and 3500 tons for the municipal light plant. Fletcher-Williams Coal Co., Columbus, bid $2.14 at the mines for Cambridge nut, pea and slack, with a premium of two cents for every 100 B.t.u. over 11,000. Calculating the coal to have 13,000 B.t.u., this would make the price $2.54 at the mines, which is slightly above the Government price. The West Virginia Washed Coal Co., of Covington, Ky., bid $2.40 at the mines for West Virginia nut, pea and slack, making the Columbus price $3.60. The contract may be awarded later.

Philadelphia, Penn.—The Reading Ry. is making a series of tests of various kinds of coal assigned to various engines. They comprise the freight, coal or long-trip engines, shifting and passenger engines. Tests made in Lehigh Valley engines with anthracite and bituminous mixed at the new mixing plant at Hazleton have proved satisfactory, it is said, and caused the Reading to look even more closely into the conservation question as it relates to engine fuel. The passenger engine from Pottsville to Philadelphia takes about 480 shovelfuls of coal to make the trip. The fast engines pulling the express consume less fuel and the locals more. It was figured in making the 1918-19 allotments of anthracite that the railroads would require 2,482,000 tons for all needs.

Columbus, Ohio—At the annual meeting of the Ohio organization of the United Mine Workers of America, protests were made against the U. S. Railroad Administration purchasing coal at lower than Government prices. A request was also made asking the Railroad Administration to so distribute its orders for railroad fuel as to give work to thousands of miners now employed on half time. Two hundred delegates attended the meeting, and it was stated that there were approximately 46,000 miners on the union rolls in the Buckeye State. A resolution was adopted in opposition to the creation of a state constabulary, as had been propesd, and to provide for which a bill is soon to be introduced in the Ohio General Assembly. All old officers in the Ohio organization were reëlected, with John Moore as president; Lee Hall, vice president, and G. C. Savage, secretary-treasurer.

MARKET DEPARTMENT

Weekly Review

Fuel Administration Announces That It Will Relinquish Control of Soft Coal on Feb. 1—Removal of Restrictions Should Serve to Stimulate Industry—No Shortage of Either Anthracite or Bituminous.

THE announcement made by the Fuel Administration that all restrictions on the movement and price of bituminous coal would be removed on Feb. 1 was received with commingled feelings by the coal trade. In its essence the order means that the bituminous coal industry is to be restored to its prewar status, with everything that the restoration implies. Among other things the zoning of bituminous coal will be eliminated and prices of soft coal will be governed by quality; in other words, the economic laws of supply and demand will once more prevail.

In a sense the removal of Government control of the soft coal industry should serve to act somewhat as a stimulus to production. Contracts for the coming coal year can now be entered into without fear of Federal interference, and the trade will gradually get back into its natural channels. The fear entertained in many quarters that the Railroad Administration would take advantage of the new order of things by using its collective purchasing power to force down the price of locomotive fuel has been set at rest by Walker D. Hines, Director General of Railroads, who in a recent statement denied that the railroads would attempt to make use of the power inherent in centralized control to the detriment of the coal industry.

Though it is unsafe to make any predictions, indications are many that the now almost stagnant soft coal market will see a decided movement for the better within the next two months. Consumers who have been cutting into their stock piles will again resume buying after Feb. 1; so will the railroads. The Government has released the shipping it had commandeered from private interests, and this more than anything will act as a stimulus to the expansion of our foreign trade. Inquiries are already starting to come in from other countries for our products, some of the steel interests reporting that export business is showing surprising activity. Resumption of operations in other fields means plenty of work for the mining industry.

Production of soft coal for the week ended Jan. 11 amounted to 10,287,000 net tons, making a total of 466,510,000 net tons from Apr. 1, 1918, to date. Only the high-grade soft coals are short in supply, there being ample of the other varieties to meet all demands.

There continues to be a large current demand for anthracite, and in spite of the remarkably fine weather there is reason to believe that this demand will continue throughout the winter. The Fuel Administration has not relinquished control of anthracite coal, and will continue for some little time to supervise its distribution.

During the week ended Jan. 11 there was produced 1,651,000 net tons of anthracite coal, making a total for the coal year to date of 76,870,000 net tons. The inquiries for stove and nut coal are greater than the supply, while the production of the other sizes of hard coal is sufficient to enable the accumulation of storage piles.

WEEKLY COAL PRODUCTION

Bituminous—The output of soft coal during the week ended Jan. 11 was exceedingly good, and in addition to exceeding the output of the week preceding showed an improvement over the corresponding week of 1918. Preliminary estimates place production of bituminous coal (including lignite and coal made into coke), during the week ended Jan. 11 at 10,287,000 net tons as compared with 8,428,000 net tons during the week of Jan. 4, and 10,163,000 net tons during the week of Jan. 11, 1918. The daily average during the current week is estimated at 1,715,000 net tons as against 1,896,000 net tons, the daily average for the coal year to date, and 1,757,000 net tons for the same period of last year.

Anthracite—The production of anthracite, estimated at 1,651,000 net tons, exceeds production during the week ended Jan. 4 by 262,000 net tons, or approximately 20 per cent., but fell 68,000 net tons, or approximately 4 per cent., below production of the corresponding week of 1918. The daily average during the current week is estimated at 275,000 net tons compared with 212,000 net tons for the coal year to date, and 319,000 net tons for the same period of last year. While the production of anthracite for the coal year to date is 1,600,000 net tons, or 2 per cent., below production during a similar period of 1918, it is nevertheless equivalent to demand. Figures now available for the nine months ended Dec. 31, 1918, show that the allotment originally outlined by the Anthracite Committee of the Fuel Administration on domestic sizes of anthracite (including pea), to have been practically fulfilled.

New England Shipments.—Bituminous coal to New England during the week ended Jan. 11 is estimated at 255,355 net tons, approximately 40,000 net tons, or 14 per cent., below the shipments during the week preceding. Rail receipts, as well as tidewater shipments, with the exception of the tonnage loaded at Baltimore, declined during the current week.

Tidewater Shipments.—A decrease in tidewater shipments of approximately 113,000 net tons, or 17 per cent., during the week ended Jan. 11 as compared with the week preceding, was brought about by the decline in shipments from New York and Philadelphia, which amounted to 33 per cent. Shipments from Baltimore were only slightly lower than the week preceding, while shipments from Hampton Roads exceeded those of Jan. 4 by 20,000 net tons, or 9 per cent.

Beehive Coke.—The production of beehive coke in the United States during the week ended Jan. 11 is estimated at 538,000 net tons, an increase over the week of Jan. 4 and but little less than the production in the corresponding week of 1918, when the output was 555,000 net tons. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania during the week ended Jan. 11 produced 309,416 net tons of coke, operating their plants at 72.6 per cent. of their full time as against 70.4 per cent. during the week ended Jan. 4. The same operators produced 146,000 net tons of coal.

Byproduct Coke.—Byproduct coke production during the week ended Jan. 11 is estimated at 541,600 net tons and falls but slightly below the production of the week preceding. It is, however, approximately 50 per cent. in excess of production during the corresponding week of 1918. The plants of the country were operated during the week at 83.1 per cent. of their full time as compared with 82.2 per cent. during the week of Jan. 4. The slight increase in loss of time during the current week compared with the week preceding was brought about by a shortage of byproduct coal in Pennsylvania, and repairs to plants in Maryland. Massachusetts, Ohio, Minnesota and Pennsylvania are the only states reporting losses of time due to lack of demand.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running lower than for the corresponding week of 1918. Road sales for immediate delivery were much larger, while those for future delivery were less than for the same week a year ago. Customers were in the house in increasing numbers. Collections are good.

Dry Goods Economist—Noteworthy progress was made this week in the movement toward more stable price levels. A steep cut was made on two standard brands of bleached muslins. Downward revisions were also made on other well known brands of bleached cottons. In floor coverings, following the recent recession in linoleum prices, reductions were made by one leading manufacturer of Wilton rugs.

Bradstreet's—In manufacturing the pace is unquestionably slower, especially so at iron and steel and textile centers, where the problem of unemployment, mostly of unskilled labor, is receiving more attention. The distictively new feature of the week is the apparent livening up of interest in what might be called raw materials, this more especially at large eastern centers, where dyestuffs, drugs, sole leather, raw wool at government sales, and hardwoods show more inquiry. On the Pacific coast, however, lumber is more active, fir prices having advanced. At some large western and southern centers inquiry for building materials, based on expected large spring operations, is more in evidence.

The Iron Age—With operations not quite so good as a week ago, it is to be expected that reports are numerous of plant shutdowns. A surplus of labor has already become apparent at steel works, with offers to work at lower than existing wage schedules. Concentration on export probabilities still serves to accentuate the unfavorable differences in ocean freight charges as between this country and England. American billets have been quoted at $50 per ton, f.a.s., while the British established export price is £13 10s. Thus the vessel freight rate difference needs to be within $14 per ton for the United States to participate. American steel bars have been offered at about $72.50 alongside ship, or about $20 per ton lower than the British product.

Atlantic Seaboard

BOSTON

Softening prices, but no better demand. Railroad contracts not renewed. Steamers still being tied up. Shipping Board announces that bottoms will be returned, but no assurance as to rates. Hampton Roads dumpings light. Only scattering lots placed inland from Tidewater. Rail movement continues to sag. Buyers becoming interested in differential between rail and water routes. New York piers embargoed. Long Island Sound market dead. Anthracite easier, but loading conditions unfavorable. Broken, egg and pea come forward, but range sizes hard to get. Allotments practically off. Dealers guarded about buying. "Independents" find it difficult to place the unrestricted sizes. Retail prices in Boston.

Bituminous—It is well established now that fair-grade Pennsylvania coals are being offered at considerably less than the Government price, although nothing more than scattering sales have been made. In fact, it is still taxing the ingenuity of several factors in the market here to place coal that has arrived at destination and is not accepted by the original consignee. Telegrams are frequent from operators who are pushed to find orders and all manner of quotations are heard. What was offered at $2.80 a week ago is now quoted at $2.60, and on some of the less favorably known coals $2.40 has been heard. Doubtless some of these offers are more or less irresponsible, so many selling agents are trying hard to induce buyers to take on temporary supplies, but it is very evident that sacrifices would very gladly be made by many operators to get orders for current shipment. A possibility of labor tie-ups and light output are used as arguments, but the trade is as unresponsive as at any time in its history. Most of the low-priced propositions are being made to the railroads, but this is because operators do not realize it is perhaps the most unfavorable prospect of all. One of the smaller roads, using about 250,000 tons, has now on hand nearly six months' supply, and all the New England lines have now so large an investment in fuel and general traffic is so light that it will be several months before there is any pronounced railroad buying. Most of the textile plants have goods on hand they cannot sell, and the whole prospect for coal in this territory is anything but encouraging.

As fast as certain of the long-term fuel contracts expire the railroads are allowing them to lapse, without any renewal. This is contrary to the expectation of the shippers and seems to be particularly applicable to coal coming forward by water. In view of all the conditions this policy is easily understood. No responsible buyer would today tie up for a term ahead on present marine freights as established during the height of war and in the midst of great shortage of shipping.

At Hampton Roads there continues a great surplus of coal over bottoms to load. Government requisitions are materially reduced, especially for the Navy, and embargoes are frequent against producers whose coal is not readily dumped at the piers. There is an entire absence of spot inquiry for cargo coal.

At this end, from Tidewater inland, there is only a light scattering inquiry. F.o.b. Providence and Boston present prices on Pocahontas and New River are from $8.10 @ 9, but the differential is so high that it is exceptional when more than a few cars can be placed.

Several of the pools at the New York loading piers continue to be under embargo, current dumping is so greatly diminished. Bunker and export demand has fallen off, and along the Sound the market is hopelessly dull. It is only with difficulty that contract deliveries are accepted, and in many cases plants that were unable to get shipments regularly last year through usual channels were so often forced into the open market that it is impossible for them now to take unfilled balances.

A great deal is being heard about fuel oil in this market. Some very attractive propositions are being made to large industries, and in the light of certain remarkable cases most factory managers will feel like making tests. This will make it all the more important from a coal standpoint to put marine freights on a reasonable basis.

Anthracite—The prolonged mild weather and the entire absence of any apprehension over supply the remainder of the winter leads the public to think the situation on domestic sizes in very comfortable shape. It is, however, a weather market, and given a spell of sustained cold there would develop a briskness that does not now appear. All-rail the movement continues very consistent, the average daily receipts at the gateways for the first half of January having very nearly maintained the December level. The present movement is about 330 cars.

Loading conditions at New York are still unfavorable. It is understood that strenuous efforts are being made with the Railroad Administration to induce high officials therein to permit Reading barges to resume loading at Port Richmond. The continuance of the unfortunate experiment at Port Reading cannot be too severely criticized, and it is much to be hoped that an efficient handling of the Reading fleet can once more be permitted. In spite of allotments and restrictions there might still be some serious situations in New England should we get some really cold weather, and further tampering with long-accustomed channels of supply should be given up the earliest day possible.

Broken, egg and pea are still in such surplus at practically all the piers that orders calling for these sizes are getting preference, and that means that a large number of smaller dealers who must insist upon a proportion of stove and chestnut are obliged to wait. The range sizes are still extremely hard to get.

Although anthracite allotments are not yet abolished, except with regard to broken, egg and pea, there are increasing indications that the shippers are no longer bound by them. The unrestricted sizes are being so freely offered, particularly by "independent" shippers, that retailers are buying very cautiously. Present prices do not encourage the dealer to accumulate much reserve of these sizes. It is now a regular practice of some of the retailers to use stone and coke crushers to reduce the size of their broken and egg.

The "independents" are finding it harder and harder to place their surplus sizes. During the tight period it was usual for them to exact the limit of price for coal and freight, and there are many retail distributors who are relieved to find themselves no longer dependent upon these sources.

NEW YORK

Anthracite market easy, with demand slow. Plenty of domestic sizes, and coal coming forward in good volume. Strike of boatmen not felt by dealers. Dumpings at local docks show decrease. "Independent" coals maintain prices. Bituminous traders expect little change due to removal of restrictions. Local situation inactive. Plenty of coal, but demand is slow.

Anthracite—The situation continues easy, with demand slow and plenty of coal coming forward to meet all requirements. Salesmen returning from their trips inland report better business and say that many dealers are keeping their bins well filled, notwithstanding, the belief that there might be a slump in prices for "Independent" coals.

The removal of all restrictions on the shipment of all sizes other than stove and chestnut, to any markets that can be found for them, has had no apparent result on local conditions so far, and it is possible that nothing short of a severe cold spell of several days' duration will create any sort of a demand.

None of the domestic sizes can be called scarce. Most dealers have a good supply of all coals, stove and chestnut being the shortest. Among the all-rail trade, most dealers ask for both sizes.

The strike of the boatmen had no effect upon local conditions. Dealers had their bins well stocked and were able to take care of the trade for several days, even though the weather had been much colder. There was decrease in the number of cars dumped at the local docks during the seven-day period ended July 17, 4564 cars being reported as compared with 5627 cars the previous week.

So far shippers of "Independent" coals have been able to maintain prices, but there is no telling how long this can continue unless this section of the country experiences some seasonable temperatures. Retail dealers are looking for concessions on this class of coal, and for that reason are not buying as heavily as they would if other conditions prevailed.

There is a heavy surplus of the smaller coals. Buckwheat No. 1 is a burden to some, and concessions are reported as being made. Rice and barley are not being inquired after. Quotations ranging from $3.25 to $3.40 at the mines for buckwheat have been noted, while it is also reported that some of this size has been offered as low as $6 alongside.

Current quotations, per gross ton, f.o.b. Tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$7.80	$8.55
Egg	7.70	8.45
Stove	7.95	8.70
Chestnut	8.05	8.80
Pea	6.55	7.30
Buck	5.10@6.05	5.90@6.25
Rice	4.65	5.10
Barley	4.15	4.30
Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The removal of the Government restrictions on the bituminous industry ordered for Feb. 1 is not likely to have much immediate effect upon local conditions. It is not probable that there will be much change from existing quotations for some time to come, both operator and shipper realizing that if the cost of production is to be met, returns from sales must be sufficient to meet this expense. When a change does occur it is expected prices will decrease due to the large stocks of bituminous on hand, the hesitancy of buyers and the diminished consumption which is to be looked for with the approach of spring and summer months.

The announcement from Washington had been expected for a couple of weeks and it will go a long way toward creating a feeling of certainty in the trade. Producers felt that it would be unwise to make any moves as to future operations until some definite announcement came from the Fuel Administration, and for that reason nothing has been done regarding contracts for the coal year beginning Apr. 1. Producers and distributors will now feel able to go ahead and discuss this matter.

The situation locally is inactive. There is plenty of the fair and poorer grades on hand, while the high coals are in good demand. Instead of the buyer going after the seller, conditions are just the reverse.

Buyers are willing to wait developments unless they can secure the best the market affords. There is a decided feeling that prices will drop shortly, and that even the better grades will be obtainable at figures below the present Government maximum.

The effects of the strike of harbor boatmen were noticeable in the number of cars of bituminous dumped at the local docks for the week ended Jan. 17. Reports show 4110 cars dumped as compared with 4996 cars the previous week, a decrease of 886 cars.

Quotations as to the various grades of coal varies. Coal in Pool II was quoted as low as $2.60 at the mines, and other good grades were quoted as low as $2.35 per ton. The better grades, however, were held steady at the Government maximum prices.

Receipts at the docks have been heavy, there having been 5408 cars on hand one day this week.

Current quotations, based on Government prices at the mines, net ton f.o.b. tide-water, at the lower ports, are as follows:

	Mine, Gross	F.o.b. N. Y., Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite trade quiet. Moderate weather halts consumption. Cancellations of egg and pea orders grow. Decline in use of pea blamed on poor preparation. Only activity is in stove and nut, and some softening indicated there. Individual shipments of these sizes good. Lifting of restrictions on all sizes but stove and nut helps producers. Steam trade very dull. Little activity in buckwheat. Bituminous market does not improve. Ordinary coals off price.

Anthracite—Again weather conditions have moderated, and while the former colder conditions were not extreme they did serve to buoy up the trade for the time. As it now stands, if the weather does not soon grow cold and stay cold for several successive weeks, almost anything is likely to happen to the coal trade.

In the suburban sections of the city the dealers are fairly busy and the demand for all sizes continues quite good. This

may be accounted for by the fact that one shipping company that has heavy obligations is still behind in its consignments to these localities. A great improvement is reported by them during the past week, however, and a continuance of substantial shipments may soon alter conditions there.

In the city proper the dealers admit being alarmed at the outlook. They are booking little or no new business, and numerous customers are refusing to accept more coal on orders placed last spring. Where dealers have filled the cellars they are fearful the coal will not be consumed in time to permit them to book orders for the usual spring tonnage.

The shippers continue to receive requests to suspend shipments of the sizes in plentiful supply, until by now there is a comparatively light market for egg, and the suburban dealers are having by far the greater proportion of this size consigned to them.

The falling off in demand for pea by domestic consumers is accounted for by several dealers who say that it is not only because of the small difference in price between it and chestnut coal, but to the size of pea coal coming to market. Unquestionably there has been much inferior pea coal shipped, and there are some who strongly suspect this size is being affected by the collapse of the buckwheat coal market.

This week the Philadelphia Fuel Administrator announced through the daily papers that the regulations of the administration are still effective and will continue so until further notice. At the same time he took occasion to announce that no fairer or more general distribution of coal has ever been made in Philadelphia. He states that every one now has coal and will get more as he needs it, also that the public has been protected against exorbitant prices. He went into a full analysis of the price question, as in these times of a full supply many consumers are inclined to quibble as to price. He showed that all the price increases were legitimate and only as ordered by the Government authorities and the far greater proportion of all increases was in the form of wages to the miners.

With the removal of all restrictions, with the exception of stove and nut, in the thirty counties in the state which had been barred from receiving anthracite since last April, the market on the other sizes is expected to improve.

The steam coal business is in poor shape indeed. No shipper is able to dispose of all the buckwheat produced, and since this size is the one in greatest demand it can easily be seen that the other sizes are particularly heavy. Many complaints are also heard of the preparation of the buckwheat, the principal one being that this size contains a much greater percentage of rice coal than usual. The smaller producers are compelled to dump much of the finer sizes on the banks at their operations, while the big companies are rapidly increasing the piles in the storage yards. This also includes a good tonnage of buckwheat, a size which heretofore this season did not find its way to the yards. There is also a heavy accumulation of the small steam sizes at all the tide shipping points. Even with prices cut almost to the bone shippers are unable to move cargoes of the sizes smaller than buckwheat. On the part of the consumers there seems to be a general disposition to wait, especially since they have large quantities of all the steam sizes in stock.

The prices per gross ton f. o. b. cars at mines for line shipment and f. o. b. Port Richmond for tide are as follows:

	Line	Tide
Broken	$5.95	$7.30
Egg	5.85	7.20
Stove	6.10	7.45
Nut	6.20	7.55
Pea	4.80	6.05
Buckwheat	3.40	4.45
Rice	2.90	3.80
Boiler	2.70	3.70
Barley	2.40	3.30
Culm	1.25	2.15

The foregoing prices cover company coal. Individual shipments on sizes broken to pea inclusive are 75c. higher. Steam sizes are sold at market prices.

Bituminous—The market fails to improve and there is more coal offered than is being taken. On account of this many operations have been compelled to go on short working time. There has even been some weakening in the demand for the high-grade coals. With the ending of confiscation of engine fuel by the railroads a heavier quantity of this coal came on the market. The situation as it now stands is that only the best coals with whose name the consumer is familiar can find a ready market at the full price. The inferior grades are still selling off price, the lowest quotation we heard being $2.35 a ton. At the piers embargoes have been placed against pools carrying low grade coals of certain kinds, although Nos. 9, 10, 11 and 71 are still taking good tonnages of the better coals.

In the trade at large throughout this district it is extremely difficult to get big users to take in any but the most meager tonnages, and some of them have even held up orders for the good coals pending their reducing present stocks.

There is some inquiry for the strictly blacksmith coals which were well-known to the trade prior to the war, as the users of these coals are now anxious to get back to the proven kinds of this coal. Of course, the business in this coal is small at any time.

BALTIMORE

Coal of all kinds in oversupply. Bituminous market glutted, prices break further and many mines curtail or close. Weather continues mild.

Bituminous—The soft coal market here has broken badly. On oversupply is running from bad to excellent fuel. Even the better grades are not so readily absorbed as desired. The less coals are a true drug on the market. Embargoes are continued from time to time against the Canton and Curtis Bay piers, and also against certain line points where congestion exists. The plan of combining one poor pool with a better pool of coal at Canton to get a clean-up at that point has so far not been a pronounced success. Coal is offering freely at figures much below the Government maximum. This includes some export coal that was originally shipped to Curtis Bay to be sent out at the export figure only. Meanwhile the producing end of the business is apparently determined that no general move to keep selling coal at figures that are not profitable shall again hold the trade. Many mines are curtailing production as fast as they find that there is not a ready outlet for their production rather than keep up the old policy of running anyhow and selling at an actual loss.

Anthracite—It is officially announced by the Maryland Fuel Administration that there is now plenty of coal here for domestic use, and in fact that there is an overupply of anthracite for the time being. This fact has been growing patent to a considerable portion of the trade for some time. The continued mild weather here for the season is holding down consumption, and there is a promise that the end of the winter term will see no big rush for fuel. The local administration also announced that all restrictions on supplies of anthracite are off with the exception that permission is still required to get hard coal in car-load or barge-load lots.

Lake Markets

PITTSBURGH

Full prices maintained for standard grades. Production considerably curtailed. Elimination of zoning system will make little change.

Complete removal of coal-zoning and price regulations on bituminous coal will take effect on Feb. 1, as announced late last week by the Fuel Administration. The lifting of the zone restrictions will not greatly influence the movement of Pittsburgh district coal, as some of the limitations had previously been removed, and the trade has not been materially restricted by such zoning regulations as have lately been in force. The elimination of price control will afford two months of a free market in which buyers and sellers can get together on contracts for the new coal year. Much satisfaction is expressed in local circles over the attitude the Fuel Adminostration recently assumed with respect to the efforts of the railroads to secure special prices on coal. Producers feel that the railroads should pay the same prices as other coal consumers.

Government prices have been well maintained on Pittsburgh district coal of the better grades, and predictions are to the effect that little cut in prices will be noted after Feb. 1. Producers of standard grades have simply refused to reduce prices when under pressure and prefer to curtail production to the extent necessary. As a result, the whole Pan Handle district is operating at only 30 per cent. of capacity, and producers in that district will be content to proceed at such a rate or even a lower one until lake shipments come, only about three months hence, to swell the demand.

High-grade gas coal continues very scarce and readily brings full prices, even occasionally a brokerage in addition to the Government limit. Byproduct coal is in almost equal demand. Dealers have been quoted slight reductions, hardly enough to pay them for handling the business, and prices to consumers are the full Government limit. The great majority of the wagon mines are now closed, as well as some rail mines producing altogether indifferent grades. For standard grades of coal the market is fairly quotable firm at Government limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

BUFFALO

No active bituminous trade in sight. Anthracite demand falling off fast. Supply everywhere good. State of consumption hard to determine.

Bituminous—Members of the trade generally agree that the supply exceeds the demand quite as much now as it has done lately, and they see no reason why the surplus will not continue for an indefinite time. A few operators are holding that the present Government prices will keep up till April and then stiffen a little on the strength of the liberal contracting that is expected. It is not easy to see, though, where this view of the market is obtained, for already jobbers are showing invoices of coal at reduced prices.

The jobbers are not really so despondent as they were when the operator had no surplus to turn over to them, for they have at least some customers on their lists and they can get as much coal as they want. That gives them two chances to the one during the scarcity period. Many jobbers shipped more coal into Canada than could be sold readily, and a few lost money by having to pay heavy demurrage; but that is stopped now, though the surplus there is still large.

Anthracite—The state of the anthracite trade is shown by the report that the independent prices are weakening and that some offers are made at prices less than those made by the large companies. Steam sizes of anthracite are not any more salable than is bituminous. Jobbers report offers of buckwheat in large lots, but they refuse it. Another way of getting rid of it is to oblige jobbers to take a certain proportion of the small sizes with every order filled for pea or larger. Even this method does not appear to help matters.

Buffalo distributors say that they now have more coal than the city retailers can handle, and if the weather does not become more severe soon the market will be flat. Canada is taking more than Buffalo in proportion, but that movement is likely to weaken if the present conditions last.

CLEVELAND

Inquiry for and buying of Lake bituminous is furnishing practically the only activity now in this market. The buying of steam coal that was done the past two weeks has flickered out. Shading of Government maximums seems fast on the way to becoming the rule rather than the exception.

Bituminous—Steam coal consumers who have been feeling out the market have left it after doing some scattering buying for spot needs and have made the local market all the duller by comparison. Operators seeking to search out business have found stock piles still a great deal larger than they expected, and the demand for steam coal now seems at the lowest ebb since the armistice was signed.

The upshot is that more and more operators have been compelled to make price concessions. Especially is this true just at present of the thin-vein operators, for whom the Government maximums were 30, 40 and in some cases 50 cents higher than they would have commanded ordinarily in competition with the more standard grades. They are now letting back the spread that ordinarily existed. It is said that it would be dangerous for any steam coal consumer to offer 25 to 35 cents under the Government price for standard No. 8 coal to any operator for a sizable tonnage.

The bright spot in the market is the inquiry for 1919 lake coal. So far prices have not been discussed, though it seems pretty generally understood not much, if anything, will be clipped off of 1918 prices unless the market in the emnatime breaks badly or the wage scales or railroad rates are reduced appreciably. In several cases blocks of about 500,000 tons have been taken. In every instance, however, this inquiry and buying has been for strictly standard No. 8 coal. Buyers can now be much more particular and no such "cats and dogs" as the war forced upon them last summer will again pass muster.

The cold spell to which retail dealers looked for increased business proved short-lived, and domestic demand has fallen back into the rut it slipped into last November. Most of the larger retail dealers look for only a limited amount of buying until next fall. Domestic consumers can now buy standard grades at 25 to 40 cents less than in November. This price cutting has been especially vigorous among the smaller dealers, who seized upon offers of thin vein and stripping coal as a reinforcement for their fast waning trade.

Anthracite—The supply, though still light in comparison with regular times, continues to increase faster than demand, and there is active competition for the retail trade. This has not assumed great proportions, however, because of adverse weather conditions.

DETROIT

Inactivity continues a conspicuous feature of the Detroit market, due to large stocks, mild weather and reduced industrial activity.

Bituminous—Neither the steam plants nor the retail dealers are making as rapid progress in reducing their cumbersome stocks as had been hoped by the Detroit jobbers. The easing off in manufacturing activity following termination of war contracts has not yet given place to a normal volume of operation by manufacturing plants on a peace basis. There is consequently a material lessening of steam coal consumption.

This defers the time when jobbers and wholesalers may look for improvement in sales to the industrial plants. A large proportion of the latter are still heavily stocked with coal, much of which is of a poor quality and the use of which is proving a costly experience to its owners. Possibly this may be offset by the feeling that in having accepted the low grade coal sent to Detroit as a substitute for their usual fuel they were rendering patriotic service in yielding the better quality of coal to aid the Government in its prosecution of the war.

Anthracite—Shipments of anthracite show little increase in volume. Mild weather has encouraged conservation of the supplies on hand, as also has the opportunity afforded household consumers to stock up with coke. The requirements of baseburner owners are not yet completely filled.

COLUMBUS

Signs of strength in domestic circles are now apparent in Ohio. The steam trade is still quiet and little is expected until surplus stocks are worked up. Prices are generally firm, although some cutting is reported.

The most interesting development in the coal trade in Ohio is the increased demand shown for domestic sizes. This market has been slow on account of large retail stocks and continued warm weather. The weather has not changed materially, but nevertheless there is a better demand from many sections. Dealers are anxious to buy the fancy grades such as Pocahontas and West Virginia splints. Ohio-mined grades are also selling fairly well and, generally speaking, the domestic trade shows a better tone. Conditions are not yet normal and will not reach that point for some time because of heavy stocks which were ,stored by householders earlier in the season. Retail stocks, excepting in rural sections, are also pretty large. Retail prices are generally well maintained, although there is some cutting reported.

The steam business is generally slow. Little demand has developed from the industrial centers where reserve stocks are unusually large. This is true of the rubber plants of Akron and the iron and steel plants of northern and eastern Ohio. Thousands of tons of coal have been stocked by these concerns, and consequently they will not be in the market for some time to come. The policy is to use up surplus stocks before buying to any extent. The railroad demand is not nearly so large as formerly, as the freight movement is cut. One of the largest lines in central Ohio, which customarily uses 10,000 tons weekly, now consumes about 3500 tons per week. This indicates the reduction in the railroad fuel demand. Some cheap coal is now being purchased by railroads, but the larger producers have not cut prices to please the U. S. Railroad Administration. The plan to stop the Railroad Administration from buying fuel under the market is progressing satisfactorily.

Production has not been large in any of the producing fields of the state. This is due largely to lack of orders, and operators prefer to suspend operations entirely rather than cut prices.

CINCINNATI

Mild weather and limited industrial demand continue to make accumulated stock the chief factor in the market. Spot demand is very small.

The local market during the past week continued under the same restraining influences which have existed during nearly the entire current season. The brief period of cold weather, virtually the first of the season, around Christmas and the first of the year, has given way again to mild weather, with moderate temperatures, with the result that even consumers without supplies of coal in storage have not been brought to worry about heat. At the same time the slow recovery of industry from the necessity of readjustment from war to peace conditions continues at a rate which does not promise much stimulus to the coal business for the time being, however flattering the prospects may be for the latter part of the year.

The amount of coal in storage does not seem to have been overestimated by the trade, as dealers and wholesalers have reason to recall the extreme activity to which they were put last summer by the incessant and insistent demand from all quarters; and they have come to the natural conclusion that they must resign themselves to a situation resulting from having handled their usual winter business several months in advance, an account of the recollection then fresh in the minds of the public of the extreme severity of the preceding winter and the difficulty then experienced in getting coal. A consoling feature of the situation is that the habit of storing coal in advance of the consuming season may have become so impressed as to help the trade along hereafter.

LOUISVILLE

Light demand only for domestic coal, while screenings and steam grade are generally quiet. Many mines down, but prices being maintained.

The demand for domestic coal is so light that retailers can generally make deliveries immediately. Retailers' stocks are somewhat lighter than they were, but they are still buying lightly.

With the demand running largely to domestic, and trouble experienced in disposing of the screenings, many operators are of the opinion that domestic will jump in value the moment the Fuel Administration prices are lifted. It is claimed that it is practically impossible to dispose of screenings at this time in quantities sufficient to take care of the domestic production, as many mines screen two cars of screenings to one of domestic, and the latter is the grade that is in demand.

BIRMINGHAM

Demand good for steam coal, while domestic coal is being eagerly sought and not much found. Labor conditions improve slightly. Output around 60 to 75 per cent. normal.

There is a good general demand for steam coal in this market, the activity being due in a measure to the shortage in supply, which has been in evidence for several weeks.

The Fuel Administration is gradually restoring distribution to the peace-time agencies, the Southern Ry. and other priority consumers now handling their requirements direct with the mines holding contracts, and purchases by the several departments of the Federal Government will now be made through the channels formerly employed.

Domestic coal is extremely scarce and receipts are much lighter than the needs, both locally and throughout the state. There is a brisk demand for domestic fuel, and the yards of the city are nearly all bare of stocks.

Labor is exceedingly indifferent and slow about returning to work, and the output of coal is still from 25 to 35 per cent. below normal. Production for the week ending Jan. 4 was 250,147 net tons, a gain of about 140,000 tons over Christmas week.

Coke

CONNELLSVILLE

Slight signs of weakness. Production increasing with prospects of decreased consumption. Byproduct coke in market.

A few days before the Fuel Administration announced that coke price limits would become inoperative Feb. 1, the first definite weakness in Connellsville coke developed, some off grades of furnace coke selling at $5.50. There was no trace of standard coke selling at below Government limits, but this may possibly occur before Feb. 1, and there may be a decided break.

The situation is a simple, almost an elementary one. Production of coke is increasing, while consumption is decreasing. There has been little blowing out of blast furnaces thus far, but this process is inevitable. The most prominent Shenango Valley merchant producer has just blown out one stack, shipments of coke for this furnace from the Connellsville region having been discontinued last week.

At a generally attended gathering of merchant pig iron producers from all over the country, held in Pittsburgh last week, the sentiment expressed was unanimous, that furnaces should not pile a ton of pig iron, by reason of present high costs, but should blow out whenever they cannot slip their current make. The furnaces want to reduce costs and they also want to have it that when the general trade revival comes there will be no stocks to act as a drag on the pig iron market. The general opinion expressed at the meeting was that eventually pig iron prices will be materially lower than present quotations, although no decline in the very near future was predicted.

The byproduct producers are beginning to offer coke in the open market, and will be able to follow the coke market downward for quite a distance, on account of the value of their byproducts. The prospect for the Connellsville region, when the market does decline, is that of accepting lower and lower prices for coke down to the point where it would pay as well to ship the coal for byproduct coking as to turn it into coke in beehive ovens. The market for byproduct coal is likely to be well sustained and afford a profitable operation. The coke market is quotable fairly steady at Government limits: Furnace, $6; foundry, 72-hour selected, $7, per net ton at ovens. Screenings from old dumps are very hard to sell at $5.25, the Government limit being $5.50.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Jan. 11 at 271,366 tons, an increase of 17,386 tons, and raw coal shipments at 170,915 tons, a decrease of 2653 tons.

Buffalo—The trade follows bituminous coal pretty closely. The furnaces are well supplied again and are taking only foundry and furnace at Government prices. Off grades are hard to sell, and fuel coke is as dull as coal. Just as soon as anthracite becomes plentiful it is hard to find a market for either gas or byproduct coke, as it does not meet the needs of the domestic consumer as well. The prospect of the usual good movement of ore and pig iron in the spring is flattering, though so far as reported no sales of ore have been made for next season.

Middle Western

GENERAL REVIEW

Mild weather still has bad effect on coal market. Brief activity in high-grade domestic coals. Little demand for steam coals. Production decreasing.

The year started out with good coal weather; in other words, the mercury was hovering about zero most of the time. However, within the last few days we have been having nice spring weather, and as a result the demand for domestic coals has fallen off, along with the demand for steam sizes. It is hoped that the weather man will be a little more reasonable in the immediate future, as the coal industry has been handicapped all through this winter season by the warm sunny days.

About a week ago there was a noticeable quickening in the market for all high-grade domestic coals. It was encouraging to note the inroads made on storage piles in the yards of various dealers scattered about the territory. The number of orders placed even went so far as to stabilize the market on high-grade domestic coals to some extent. This situation was short-lived, however, as the present warm spell we are having has put back the retailer into the state of lethargy he has been accustomed to all fall. The trade believes, however, that if we had from three to six weeks of normal cold winter weather conditions would be much better, and they are all hoping that this kind of weather is in store for them.

The steam market is practically dead, as there is little demand. Every now and then some dealer tries out a car of new coal, but this desultory purchasing doesn't have any effect whatsoever on the market. Railroads are still purchasing, but it is believed that they will soon have enough to enable them to issue some orders on the requisitions they have placed with Mid-West operators.

The mines specializing on steam coal are not looking forward to any great activity in the steam market until at least the first of April. The latest reports from the Geological Survey at Washington show a sharp decrease in tonnage produced. In fact, the tonnage production is dropping like a plummet. It was stated that during the week ending Dec. 28, less coal was produced in the United States than for any like period during the last three years. It is our opinion that this decrease in tonnage will continue, as it is the only logical cure for an overproduction. Operators are becoming philosophical on this point, and are prepared to operate their mines less than half time from now on, as they see that this is the only cure for the situation.

CHICAGO

Little demand for either steam or domestic coals. Trade is concerned about future Fuel Administration activities.

Market conditions in Chicago are no different from general conditions existing throughout the Middle West today; in other words, what little demand there was a week ago for domestic coal has died off, and there is little call for steam sizes. The all-important question in the mind of the trade here today is, what the future activities of the United States Fuel Administration will be. Some say that the Administration will practically go out of existence, so far as zones, prices, etc., are concerned, on or about Feb. 1. There is some talk that the Fuel Administration will continue in office until we are well on into next summer. The State Administration maintains a discreet silence on all questions, but it is believed that they are looking forward to the abolishment of all zone restrictions under date of Feb. 1.

MILWAUKEE

Mild weather makes mid-winter coal market dull and unsatisfactory to dealers. All restrictions as to anthracite delivery removed by the fuel administration. Ample stocks on hand.

Mid-January finds the coal market at Milwaukee in a limp and pessimistic condition. Continued mild weather has operated to keep down the demand to such an extent that the inroad upon stock piles of soft coal is scarcely noticeable. It is now thought the supply of hard coal, which was short of the usual quota at the beginning of the season, will be sufficient to last till the opening of navigation in the spring.

The movement of bituminous coal to the interior is slow for the season. There has been little demand, and in some cases advance orders based upon needs in former winters have been rescinded. Should present conditions continue, there is bound to be considerable bituminous coal left on the docks when spring is reached.

Hard coal prices remain at the prices last fixed, which range from $11.05 for pea to $12.52 for chestnut, with an extra charge of 50c. for carrying in. Dealers report a disinclination on the part of consumers to pay the prices asked for hard coal, and soft coal is ordered instead.

After several weeks of parley, the county fuel administration has established the price of byproduct coke at $11.50 per ton. When this price was fixed upon in December last, the producers of byproduct coke objected strenuously. The matter was appealed to Washington, which office fixed the price at $10.40, but subsequently rescinded its action and accepted $10.50 as the price. Egg, range and chestnut sizes, which had been selling at $12.25 per ton carried in, are now offered at $11.50.

Fires in soft coal piles are still smoldering in some yards, entailing labor and expense in shifting the burning product.

ST. LOUIS

Mild weather causes local market decline. No steam demand and little domestic with an abundance of all kinds of Illinois coals. Mines idle and much unrest among the miners. Transportation and car supply good.

In the Standard fields mines have been idle for an entire week on account of the inability to move steam sizes. The domestic situation is not much better. There is a light demand in the sections that live from hand to mouth, but a big supply of coal stored last summer will more than last the consumer throughout the winter unless we have from four to six weeks of the severest kind of winter weather.

In many of the smaller places outside of St. Louis similar conditions exist; many retail companies will be doing remarkably well if conditions permit them to break even.

The recent announcement that anthracite egg will come to St. Louis was bad news to the dealer who has a supply of Arkansas, and gashouse and byproduct coke. It would have been hard to move the storage supplies of these fuels even if anthracite did not come in until after Apr. 1.

The country demand is extremely easy on both steam and domestic. What little coal is going out does so in scattered shipments.

In the Standard district the Baltimore & Ohio keep mines idle for four days on account of no cars. The Baltimore & Ohio and Louisville & Nashville seem to be stumbling blocks at this time. The Illinois Central shows some wonderful improvement, the other roads being about normal. There is a slight falling off in the showing made by the Iron Mountain in moving loads, and the Terminal seems to be slipping a few cogs in its ability to care of the business offered it.

The Standard field is in a deplorable condition. The operators in this region are unorganized, and incompatible. Some mines are unable to work on account of too much lump and egg, and a few miles away mines are idle because they cannot move the screenings though they have lots of orders for lump and egg. As long as the Standard operators continue to flounder around in this manner just so long will they continue to sell coal at below the cost of production. With mine-run costing between $1.50 and $1.60, the following prices prevail on Standard coal: 2-in. screenings, $1.25; 2-in. lump, $1.50; 6-in. lump and 2 x 6-in. egg, $1.75 up; all depending upon how much the operator can squeeze out of the buyer.

In the Mt. Olive district there is an abundance of coal and mines are idle, but everything is quiet and the operators seem to be able to handle the situation fairly well. They are maintaining their prices for the most part at $2.55.

Railroad tonnage is fairly good out of the Mt. Olive field, and the railroad tonnage in the Standard field is fair but not what it should be because the storage piles are being used up.

In the DuQuoin and Carterville fields there is at the present time an overproduction, but the railroads are helping out by buying.

There is practically no Arkansas coming in here now. Coke is a drug on the market at any price. About 100 cars of anthracite coal were ordered for St. Louis recently. This is all egg size, but none of it has arrived up to the present.

Ocean Shipping

FOREIGN FREIGHT RATES

W. W. Battie & Co.'s coal trade freight report for Jan. 20 states:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates.) On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Rangs, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net to Rio or Santos, $18.50 net to Buenos Aires and $19.50 net to Montevideo.

Export Notes

EXPORT LICENSES TO MEXICO

The War Trade Board announces that the regulations announced in W. T. B. R 320, issued Nov. 19, 1918, to the effect that applications for export licenses to Mexico should have attached thereto the order from the consignee bearing the visé of an American consul, have been withdrawn. Orders for shipments to Mexico will no longer require such Consular visé and need no longer be attached to the application for export license.

EXPORTATION OF COAL

The War Trade Board announces that applications will now be considered for licenses to export coal to all destinations in Europe and to the Argentine and Uruguay. Applications should be filed in the regular way required for the filing of applications for the exportation of other commodities to the particular country. Licenses for the exportation of coal to the Argentine and Uruguay will provide as a condition thereof that the shipment must be consigned in care of the War Trade Board representative at Buenos Aires or Montevideo, as the case may be.

COAL AGE

Volume 15 New York, January 30, 1919 Number 5

Prices, Wages and Business

By Floyd W. Parsons

IT NOW appears that general prices of commodities will experience no sudden drop. The reasons creating this situation are the scarcity of foodstuffs and the lack of certain important raw materials. A further reason is the assurance that expanded currency and credit will contract more slowly than the volume of business. True, there is already a downward trend in the prices of most commodities that have entered largely into the manufacture of munitions; but even this adjustment shows no indications of being precipitate.

In practically all industries American corporations have been fortified against the dangers of reconstruction by the creation of substantial reserves for plant changes and the depreciation of inventories. The war's demand for quantity production brought about important changes in industrial processes and caused improvements in machinery, which has resulted in an increase in the output per unit of labor. Great benefits will come from this and the standardization of industrial methods. The war also has given us many new industries, such as shipbuilding and the manufacture of chemicals and dyes. These new businesses will afford an additional outlet for our enlarged production of raw materials.

During the period of the war this country increased its pig iron production 22 per cent., its copper production 17 per cent., and its coal production nearly 33 per cent. This immense industrial development renders it necessary that we add additional foreign markets to those America supplied in pre-war times, and contrary to the belief of many, our greatest opportunities do not lie in Great Britain, Belgium and France. Those nations will purchase from us many of the things we sold them prior to the war, but indications now plainly show that these allies will be able to take care of most of their own reconstruction work.

Belgium's fuel requirements present no insurmountable problem, for the mines of that country can be rebuilt with the same rapidity as can the Belgian industries, and as to her general needs, we must remember that Belgium has large raw-material resources in the Congo. As for France, we now know that southern France has undergone an industrial expansion almost equaling, and to a large extent counteracting, the devastation work of the Huns in northern France. When the armistice was signed France had 35,000 more people working in her various industries than were employed at the outbreak of hostilities. The nation is better able to supply its present needs than most of us imagine.

We in America should profit by the lessons in economics resulting from the Napoleonic and American Civil Wars. The situation then was saved by the returning soldiers settling on new lands; thereby developing new areas and creating new markets for industrial products. In the years immediately after our Civil War, American industries grew steadily and more than doubled in the 15-year period from 1865 to 1880. The greatest influence back of this prosperity was the growth of population in hitherto unsettled regions. The world's undeveloped area today is relatively as large as it was then, due to improvements in transportation facilities. Distance has been largely eliminated.

America has changed from a debtor nation of $5,000,000,000 to a creditor nation of $8,000,000,000. Our people have been converted into a nation of bondholders. It is only reasonable to expect that Americans will place a considerable part of their savings during the next few years into foreign bonds, and this will go a long way toward solving the problem of financing our export trade.

Unless we lose our heads, it will not be many months before the United States will enter a period of prosperity that will surprise even the most ardent optimist. The speed and success of this industrial expansion will depend on our Government accepting its present opportunity. To go ahead, the greatest need is for increased transportation facilities. We must have adequate terminal arrangements to avoid congestion of traffic, enlarged port facilities, greater development of waterways, better national highways and more irrigation projects. All of these developments are essential to national expansion and will afford employment at an opportune moment for thousands of men released from our military forces. Supplementing such action, let our legislators modify their pre-war policy toward industries, removing harmful restraints. We must, of course, prevent monopolistic practices, but we should also provide for large-scale production without the waste brought about by senseless competition.

If America in coming months meets with embarrassments in her industrial life, the fault will lie in her failure to meet the situation with courage and sense, for never in history has a nation been so well advertised and so favorably known throughout the world.

IDEAS AND SUGGESTIONS

Determining Length of Diagonal Crosscuts Between Parallel Headings

BY P. M. SHERWIN
Blue Diamond, Ky.

At many of the smaller coal mines that do not employ a resident mining engineer, considerable difficulty is experienced when, in order to pick up a lagging parallel heading or drive a haulway at other than right angles, it is desired to know just when to stop driving in order to keep the heading centers at the proper distance apart. The diagram below is to be used in connection with that

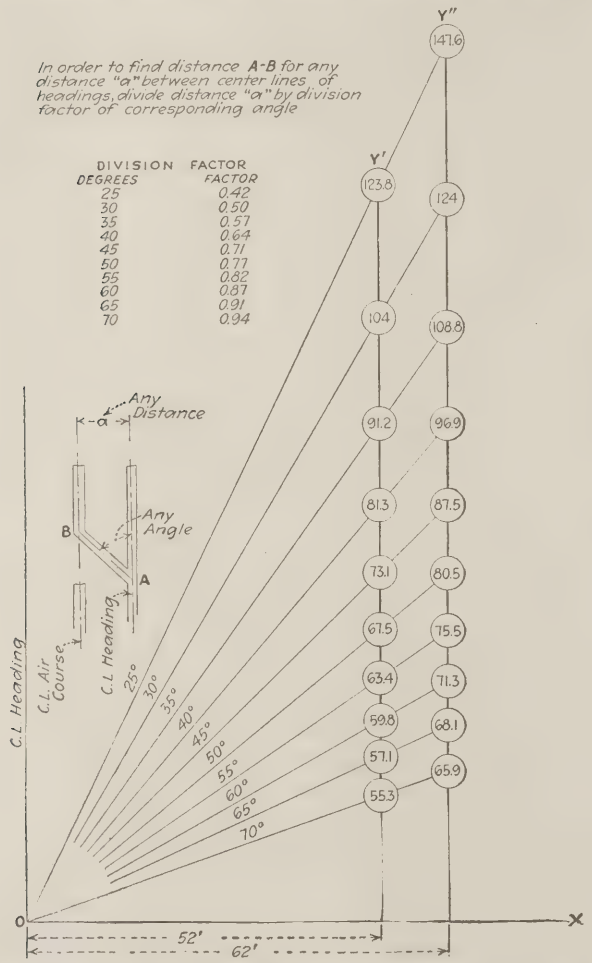

DIAGRAM GIVING DISTANCES FOR DRIVING ANGLES

shown on page 9 of the "Coal Miner's Pocketbook," 11th Edition. This latter diagram tells how to lay off certain angles without a transit, while the one shown here will give the distance that should be driven on the corresponding angle.

This particular diagram has been evolved for the use of the mine foremen of the Blue Diamond Coal Co., in the mines of which the main headings are driven on 62-ft. centers, and room headings on 52-ft. centers. In order to find the proper distance center to center, follow up the perpendicular line which corresponds to the distance between headings until the line of the angle used intersects it. The figure found there will be the distance to the center of the parallel heading. When the angle is more than 70 deg. the distance will be so nearly equal to the perpendicular distance that the latter, with a small allowance, can be used.

By using the division factors a diagram may be constructed for any distance between entry centers. The division factors are the natural sines of the angles. The distance to the right from O along OX should be laid out to scale. In the accompanying diagram a scale of 10 ft. to the inch has been used. When this work is done accurately the same scale can be used to read the required distances directly along the lines of the angles starting from O to the point of intersection with the vertical lines Y' and Y''.

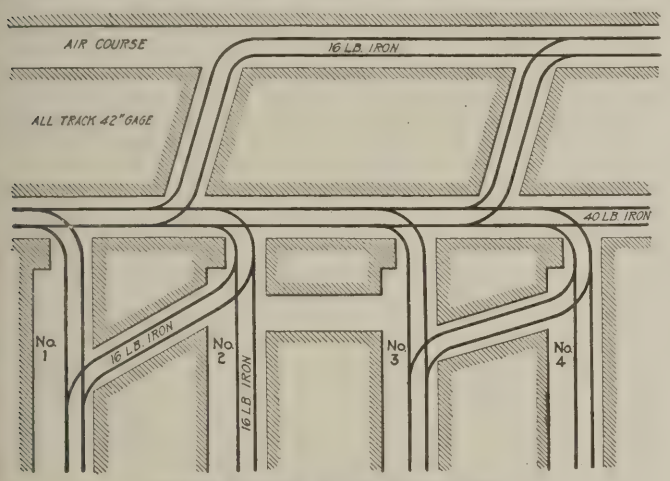
This diagram was suggested by H. H. Braden, superintendent of the Blue Diamond Coal Co., and was worked out by myself.

Remelting and Using Old Metals Proves Economical in Practice

BY FRANK HUSKINSON
Trinidad, Colo.

The majority of mines simply scrap all brass and white metal bearings and bushings when they become too badly worn for further use. This is a waste of good material that can readily be converted into new bearings more cheaply than new ones can be bought. With remade bearings, also, a better fit can be secured. New bushings from the factory are always of a standard size, and a shaft generally wears more or less after being in service for some time, and in many cases has been cut down to a smaller diameter.

I have followed the practice of melting old bearings and bushings and pouring them into suitable molds, then boring and turning them to the proper size on a lathe. In melting old brasses and white metal bearings I use a good sized ladle and a forge fire.



In melting white metal to be cast into molds, the heat should be brought up gradually. As soon as the metal is melted the top should be covered with powdered borax, and enough heat applied to bring the metal up to the pouring point. If the metal is melted and brought to the pouring point without covering with the borax, a portion of the alloy, such as zinc, will oxidize and be lost. The action of the borax is that it smothers the metal and prevents any of the alloys separating. When pouring into the molds the borax cover is simply held back, allowing the clean metal to be poured off.

Ordinary brass scrap can be melted in the same manner and poured into molds. Precautions should be taken, however, not to overheat any metal. Enough heat should be applied to bring it to the pouring point. Care should be taken to see that all molds are free from moisture, as molten metal and moisture do not agree.

Peculiar Arrangement of Mine Track

By Mine Foreman
Hanover City, Penn.

We are using a track arrangement in the mine where I am employed that might benefit some *Coal Age* readers. The heading in question is being driven to the rise and considerable energy is required to push a car around a room switch. Consequently, I arranged the track as shown in the accompanying illustration. When the locomotive comes in with the empty trip the motorman pushes five or six cars into rooms Nos. 2 and 4. The men can handle them from the track between the

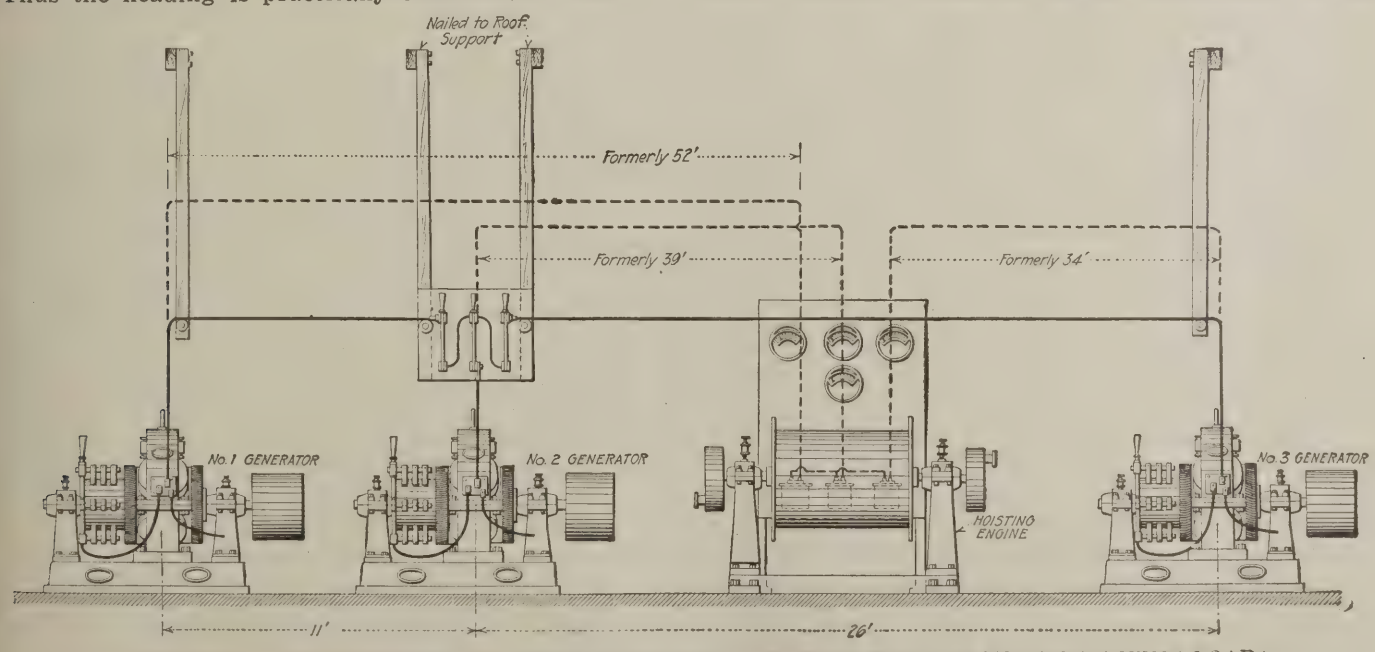
HOW TRACK WAS ARRANGED

rooms, as may be readily seen. When a car is loaded it can be left in the roomneck and not dropped out onto the heading. This is advantageous to the cutter, as he can travel along the heading and not have to shift cars.

The arrangement shown takes considerable track work, but I believe it pays. The men are better satisfied and the cutter can get around much faster. We also use it in the air course. The motor pushes empty cars into the shoofly, or diagonal crosscut, nearest the face of the heading and the men drop the loads out of the lower shoofly, or rather keep them off the heading. Thus the heading is practically clear at all times.

Equalizing the Generator Load

By J. J. Nolan
Linton, Ind.



This description and the drawing shown below may interest some readers of *Coal Age* who have, in their plants, similar conditions to those here portrayed. The plant referred to, together with the mine it serves, was purchased by the company with which I am connected about three years ago. The mine is a large producer of coal.

The power plant building was intended for only two generators, but a third was added by the former owners, to take care of the increased load. As might be expected, this caused quite a difference in the length of generator lead cables.

When carrying a fair load the belts and engines put one in mind of a horse race. First one and then another had the lead. When the load was light they would motor each other, causing bad communication at times and continual moving of the rheostats throughout the day. The three generators and hoisting engine were set side by side in almost a straight line, while the switchboard was 25 ft. behind the hoist and erected on the rear of the hoisting engine-room platform without taking into consideration the efficiency of the generators.

The change, as may be noted, was not expensive and effected quite an improvement in the operation of the generators. The only extra work imposed on the engineers is the task of walking around in the morning at starting time to throw in the equalizer switches and pull them out after the day's run is over.

If only two generators are operated, the connections on single-pole switches are arranged so that any two machines can be used. The long equalizer cables going to the board were employed to increase the capacity of the positive and negative of No. 1 and No. 2 generators, these machines being farthest away. The change did away with several connections on the rear of the switchboard and equalizing bus too, giving much more room and necessitating less complicated wiring.

SHOWING ARRANGEMENT OF GENERATORS AND HOISTING ENGINES FOR EQUALIZING LOAD

Chain Making and Repairing in the Mine Blacksmith Shop

By J. T. SPRINGER
New York City

SYNOPSIS — *The average coal mine blacksmith has a wide variety of work to perform. Although most of this will be repairs, some manufacturing may well be done. Car couplings and special chains fall in this category. The manufacture and heat treatment of chains and chain links is here described.*

NATURALLY, the amount of blacksmithing done around a coal mine is considerable. One of the large items will be the forging and hardening of cutter bits. In addition to this, however, there will be miscellaneous work covering a wide range. Consequently, the mine blacksmith needs to be a good all-around man—one who can do the usual things and also one not afraid to tackle a job out of the ordinary. Much of the miscellaneous work will be repairs, but some items—for example, the chains and coupling links used in and around a mine—may well be manufactured in the mine shop. It is the purpose of this article to give practical and reliable information that, if properly utilized, will tend to make the mine its own producer as well as repairer of chain, coupling links, chain hooks, etc.

Let us begin with the chain hook. This may be made without a weld, so that the problem is one of forging. There may be, in addition, an annealing operation. Suppose that the hook desired is to be 3 in. long, is to have a $\frac{5}{8}$-in. entrance opening and a $\frac{3}{8}$-in. eye-hole. Such a hook may frequently be conveniently made from $\frac{1}{2}$-in. round stock. A short length a trifle over double the length of the finished hook is cut off. This piece will be, say, $6\frac{1}{2}$ in. long. Since it is desirable to form the eye without welding, it is necessary to upset one end in order to secure enough metal. A mark may be placed, say, $1\frac{1}{2}$ in. from the end of the blank as a reminder of the amount of stock that should go into the cruller-shaped eye.

To do the upsetting, the smith will heat the marked end to a medium forging heat and cool off the metal between the mark and the farther end of the blank by means of water. The water may be applied with a hose, by pouring, or by dipping the blank into the bath a sufficient distance. The object of cooling the major portion of the bar is to prevent movement of the metal throughout that part of the blank during the upsetting operation.

The actual upsetting may be accomplished in either of two ways: (1) The blank may be held vertical on the anvil with the hot end up and the hammer used to beat the hot metal down until the $1\frac{1}{2}$ in. has diminished to 1 in. This amount of shortening and consequent thickening will be about right for an eye $1\frac{1}{8}$ in. in diameter, with a $\frac{3}{8}$-in. hole. The ring of metal will have a thickness of about $\frac{3}{8}$ in. (2) Instead of holding the hot end up, it may be held down on the anvil, while the hammer or sledge is used against the cold end. There is, perhaps, some objection to this latter method because it tends to waste the heat. The anvil, being cold, absorbs heat from the hot end of the blank and may thus interfere with the upsetting operation. One or two men may do this work. This depends upon circumstances and the skill and strength of the smith.

After the shortening, the upset end is heated up again and the upset metal flattened out to form a circle about 1 in. across and $\frac{3}{8}$ in. thick. It is possible that there will be manifested a tendency of the eye blank to increase more in one direction than in another as the flattening proceeds. In such case the hammer may be needed to give a few upsetting blows. The eye end of the blank may be held against the edge of the anvil during this operation.

After a proper circular form $\frac{3}{8}$ in. thick has been secured and the corners rounded, the eye blank may be heated again and a $\frac{1}{4}$-in. hole punched. The punch will doubtless get warm and need an occasional dipping into water to maintain it at proper temperature. The punching of the hole may be done partly from one side and partly from the other. That is, the punch is made to

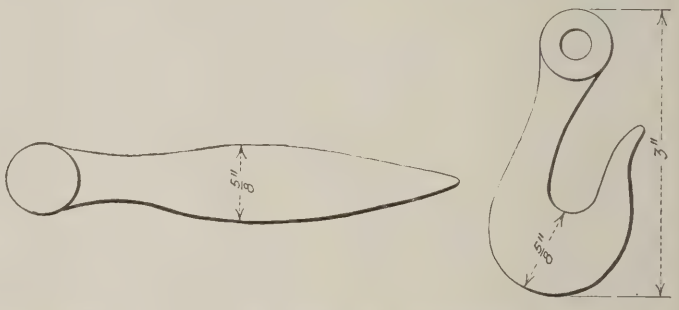


FIG. 1. HOOK BLANK AND FINISHED HOOK

penetrate about halfway from one side and the same operation repeated from the other. A small core will be formed, but this may be driven through the hardie hole or the pritchel hole of the anvil. Some blacksmiths put a small amount of coal or coke dust into the depression made when the punch has got well started. The driving of the punch will then be facilitated, because its end will not heat up so readily.

The finishing of the eye yet remains. While no substantial weld is to be made in the hook, it will be well to heat the eye to a welding heat and to beat in and together any stray fibers or filaments. The punch or a suitable mandrel should be stuck into the hole and allowed to remain there during this operation. In fact, the final shaping of the metal to form a smooth rounded surface may well be done at this time.

The punch may need attention from time to time to keep it in place. The redriving of this tool to keep it right, and perhaps other movements, will naturally result in opening up the hole a trifle beyond the $\frac{1}{4}$ in.

If a hole precisely $\frac{3}{8}$ in. in diameter is required, it may be well to finish with a $\frac{3}{8}$-in. punch. The eye should be well rounded so that it will not tend to wear on the link or bolt passing through it.

The remainder of the forging of the hook will now be rather simple. The main portion of the blank is heated and flattened to the $\frac{3}{8}$-in. thickness. It is desired to have the metal swell out at about the halfway region of this main portion or where the bend of the hook will be made. A sufficient widening may well occur during the flattening to $\frac{3}{8}$ in. If there results a swelling to $\frac{5}{8}$ in. this will probably be about right. The piece is tapered, but rather gently, between the eye and this broad section. This tapering operation will tend to lengthen the whole piece and must not be carried so far as to thin the metal below the thickness of $\frac{3}{8}$ in. On the other side of the broadened region the piece is tapered rather more decidedly to a tip at the end. The entire length of the piece should now be about $6\frac{3}{8}$ in. The corners are rounded and the hook-shaped form imparted. This latter is done on the horn of the anvil with the aid of a light hammer. All that has been said about forging, punching, bending, etc., will apply equally well to similar operations on other classes of work as well as upon hooks.

The making of chain links divides itself naturally into light and heavy work. Perhaps the most severe operation is the bending of the blank to the link form. When the size of the stock is sufficiently small to make this an easy job for one man, the whole work of forming and welding the link may well be termed light chain making. If the bending requires two men, we have heavy chain making.

The chain and links used at mines may include both classes, although the heavy chains will not run up to such enormous affairs as those used at the locks of the Panama Canal or those employed for mooring battleships. Chains have been made up to the size where the stock used was $4\frac{1}{2}$ in. in diameter. While the mine will not have any work of this description, it may possibly have chains and links made from stock heavy enough to require two men to form and weld.

Chain links are open, if the link is a simple oval. Stud links are those which have a crosspiece amidships dividing the open space into two apertures. The crosspiece is called the stud. This is welded into place and naturally stiffens the link. Undoubtedly, an open link provided with a suitable stud is stronger than it was before. But this is not the proper way to make the comparison. The real question between open and stud links is whether it is better to put additional metal into a stud or into the plain oval, thus giving the sides of the link a larger cross-section. I doubt if this question has been satisfactorily answered. Considerable chain of both varieties tends to show that a strong difference of opinion exists.

Links may be welded on the side or at the end. The end-weld link seems to be the better type, especially for large stock. Even for small stock, the objection that the side-welded link is apt to be one in which the two parallel sides under heavy stress do not yield the same has to be considered. There is a remedy, more or less adequate, in the shape of heat treatment. Unless this is to be applied, it is probably better to decide against the side-welded link.

If, however, heat treatment is to be employed, and those in charge are going to insist on sufficient experimentation to guarantee a satisfactory procedure, the side-welded type may be used and the advantage of easy bending gained; for the side-welded link is more easily bent in the region of the weld for the reason that these bends are further from the ends of the blanks and may consequently be made with the assistance of a greater leverage. The two bends near the weld of an end-welded link lie quite close to the stock ends and naturally present some degree of difficulty for that reason.

The length of stock required for a link will naturally depend on the inside length of the link, the inside breadth and the diameter of the stock. These three factors are the ones that principally govern. The precise form of the oval will also exert an influence; but, ordinarily, the foregoing items are the ones that control.

I will give an example or two by way of illustration. A well proportioned link made from $\frac{3}{8}$-in. round stock will have its inside length equal to $1\frac{5}{8}$ in. and its inside breadth to $\frac{3}{4}$ in. With these dimensions as guides, a neat form of link may be produced with straight parallel sides and circular ends. The overall length is $2\frac{3}{8}$ in. The length of stock required closely approximates $5\frac{1}{2}$ in.

This style of link may be made in various sizes by using the following formula:

$$L = 14.1 \times d$$

Where L = the length of stock in the blank and d = the diameter of the stock. Both are expressed in the same unit, such as inches or centimeters. The link produced will have an inside length of about $4.33d$. The overall length will be about $6.33d$, and the inside and overall widths, $2d$ and $4d$ respectively. The diameter of curvature is $3d$. The curvature is here reckoned as that of the axis of the stock. The curvature of the horn of the anvil where the bending may be done will be $1d$ less—that is, $2d$.

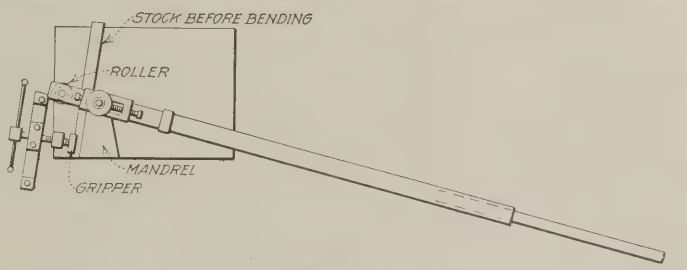

FIG. 2. JIG FOR BENDING LINK STOCK

Another type of link is the ship's cable form. Here, with 3-in. stock, the blank is made about 37 in. in length, which is decidedly shorter than would be the case with the link formed according to the formula already given. That formula would require 42.3 in. of stock. This marine link is accordingly somewhat shorter relative to its breadth. This is perhaps an advantage with big chain in preventing tangling.

In order to determine the number of links required for a given length of chain, we divide the chain length by the inside length of the individual link. The chain length is here taken as the usable length—that is, the distance from the inside of the free end of one terminal link to the inside of the free end of the other terminal link.

To make the small link described from $\frac{3}{8}$-in. stock, the

smith cuts off 5.3 in. from a stock bar. This is 14.1 times the $\frac{3}{8}$-in. diameter. The ends are cut square. The blank is now heated to a cherry red and then bent to a U-form. The curve is to be $2d$ in diameter, or in the present case, $2d = \frac{3}{4}$ in. Consequently, the bending may be done at that point on the horn of the anvil where the calipers show the diameter to be this amount. If a good many links are to be made, it may seem desirable to arrange a steel bar horizontal or vertical and to do the bending around it. The bar will naturally be of $\frac{3}{4}$-in. round stock or be forged to this size. The advantage over the anvil would be the elimination of the necessity of continually noting at just what point on the horn of the anvil the bending is being done.

The scarfing of the ends may be done by the following method, which is the one recommended by T. F. Googerty. The U-shaped piece is held on the left-hand corner of the anvil at the base of the horn with the legs of the U making an angle of about 45 deg. with the edges of the anvil. Both legs are held with their ends on the anvil top, the right-hand leg having but a small amount of bearing while the left-hand leg has perhaps a third or more of its length overlapping. The smith then strikes a blow with his hand hammer on the hot U-shaped piece. Before striking again, the piece is shifted a little. That is to say, the end of the right-hand leg is held to its original position and the

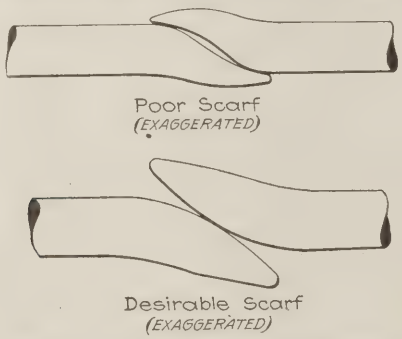

FIG. 3. GOOD AND BAD SCARFS

other leg withdrawn a trifle from the anvil top. In a sense, the one end rotates (in a horizontal plane) about the other end. By striking and shifting, striking and shifting, in the way described, a bevel may be produced. "The scarf consists of a series of slanting notches."

In scarfing it is desirable—not to say necessary—to produce two convex surfaces, to oppose each other at the moment of welding, rather than two concave surfaces. That is to say, when the ends that have been scarfed are overlapped for the purpose of welding, convexity should oppose convexity. Doubtless this requirement is more important with big links than with small ones. It will be best, however, to observe this rule, regardless of the diameter of the material.

It is not considered good practice in chain making to make two links and then thread the intermediate one into them and weld it shut. When one link is made, the next is threaded into it and welded; then the third link is threaded into the second and welded; and so on. In this way the chain grows link by link.

Let us return now to our small link. The U-piece has had its ends properly scarfed. It is now necessary to bend them toward each other, thus forming the end of the link by overlapping. Naturally, the smith will use the horn of his anvil and bear in mind the curvature he ought to produce; otherwise he will use some substitute for the horn, such as the rod of uniform curvature already suggested.

After proper shaping, the link may be heated and welded. The threading onto the chain already made may well be done after shaping and heating for the weld. This gives opportunity to do all the heating without the nuisance of the interference of the chain already made.

Naturally, the sizes of chain used about a mine will not involve the handling of excessively heavy links. At the same time, the smith may be called upon to handle sizes where he will need assistance in the bending and other operations. The blank at first is straight and the ends are cut off square. The whole piece is heated, but the center is given more heat than the ends. If the size of the blank permits, the heating may be done without reversing the piece. Should this be necessary, however, it may be done; but, if possible, the smith will aim to do the heating without such reversal.

Bending the Link

The bending of the blank is accomplished either on the anvil or by means of a suitable jig. The weight and stiffness of the blank will naturally guide the smith as to what he should prepare for. At any rate, a bending device is readily made and will be quite useful if the smith has much heavy work to do in making coupling links or the like. For this purpose a slab of metal is provided for the base of the device. On this slab, near one corner, a mandrel is firmly secured. This is a block of metal having a form suited to guide the bending of the blank. Naturally, the mandrel will present the outline of a U or of a V with rounded point. The edges of the mandrel against which the blank is bent may be grooved. This is probably unnecessary with links of moderate size. The blank is, at the time of bending, placed close up against one side of the mandrel and securely held there. The portion not in contact is then forced around the mandrel block.

The bending is done with a lever or sweep, pivoted on the nose of the mandrel and arranged to rotate in a horizontal plane. At the short end of the sweep, a roller is arranged to bear against the blank as it lies against the mandrel. By swinging the sweep in the proper direction, the roller forces the blank to conform to the shape of the mandrel. In the work occurring in and around a mine, it will hardly be necessary to provide anything more than some suitable holes in the slab and some plugs or studs to fit into them. A plug may be set in place to hold the blank. An ordinary swage block may often be used for this purpose.

Whatever the desirability of using a special device may be, the smith will probably find that he can, at a pinch, do some pretty heavy bending on the anvil, especially with the aid of a helper.

With the same heat that was used for bending heavy stock the turning in of the ends may be accomplished in part. With small chain, including possibly all sizes wanted at a coal mine, it may seem better not to attempt any end-bending immediately after the bending of the blank at its center. With moderate and small sizes it may be much more convenient to do the scarfing while the U- or the rounded V-shape is maintained. It appears to be good practice with big chain to do the

scarfing after the ends are started upon the inward bend but before the full operation is completed. A difference thus exists in handling big and little work. The smith's own judgment will determine where the dividing line is to be drawn.

I have already pointed out that the convex form of scarf is to be preferred to the concave. This is an important matter, as good scarfs tend to produce good welds and poor scarfs tend to produce poor welds. The reason appears to be this: With concave scarfs, there is a tendency to include dirt or foreign material of some kind between the surfaces to be welded. Convex scarfs tend to crowd such material out of the weld, particularly if the hammering begins in the center of the welded region. Material included between the surfaces in a weld means an area of no union of metal. A further point about scarfs is concerned with the character of the edges. There should be no sharp and thin edges or other parts because when the high heat necessary for welding is applied such parts are liable to damage by oxidation. Consequently, it will be well to round all edges and terminal portions.

Where the scarf surfaces will not get dirty from the fire when the welding heat is imparted, it may prove useful to roughen or score them with the edge of the hammer. But if dirt may be gathered by such indentations, it may be better to provide thoroughly smooth surfaces. Where dies are employed in scarfing, scores in the upper die seem to be of service in producing better welds.

The Proper Length of Scarf

The length of a scarf is also a matter of some importance. A tendency exists with some to make the scarfs too long. It is recommended that they be somewhat longer—say, 50 per cent.—than the thickness of the stock. "If the scarfs are too long, they will overlap one another too far and can not be welded down quickly enough. If too short, they hammer down too quickly to make a good job, and the weld will be thin. If the scarfs are the right length and about the same size, which is important, the weld will finish down in good shape and make a smooth job, providing the ends are clean. When the pieces being heated look as though they are covered with grease, you may be sure the fire is dirty, or is too new." "The fire must be a clean one. A well burned fire is best. A new fire is not a good one to raise the welding heat in, as there is too much smoke and green coal that comes in contact with the metal."

In both forging and welding much depends upon the character of the fire. Ordinary soft coal is unsuitable, because of its sulphur content. There are some special seams or beds of soft coal which are more or less free from sulphur. Such fuel is, perhaps, permissible, but wood charcoal is more suitable. Coke contains less sulphur than the coal from which it is made. Anthracite is also a usable fuel. Fuel oil is suitable, provided the furnace arrangements are such that the metal is not close enough to the burner to encounter the gases before combustion is complete.

The welding heat is about 1900 to 2000 deg. F. It probably varies with the carbon content of the steel. At any rate, the metal will not only be yellow, but will be around a white heat when it is in proper welding condition. At first, the blast is operated slowly. When a yellow color appears, it may be increased. The ends should be managed so that both are heated alike. It may be necessary to keep a pretty close watch in order to cover this point. Attention may be given also to the edges and thinner portions of the scarfs to see that they do not heat up too rapidly as compared with the rest of the scarf. "It is a good plan sometimes, when the pieces are about a yellow heat, to shut off the wind for a moment and let the pieces and fire even up, and give the heat a chance to soak through them. As the pieces become nearly white, the blast is increased."

The length of time between taking the work out of the fire and actually beginning the welding operation is important. A striking illustration of this was afforded by the case of five doublets (two links) tested to breakage. All were made of heavy stock and with oil heating. The first doublet, however, was made with the regular man in charge of the crane, which transported the work from fire to anvil; the others were made with an inexperienced man in charge of the crane, who was able to manage only one movement at a time and so secured slow transportation. The first doublet broke at a stress of 568,100 lb.; the remaining four at an average of 489,410 lb. This was a loss of 14 per cent. in strength.

Necessarily the steel or iron used in making chain is damaged by the very process of manufacture. This damage may, however, be confined mostly to the welding. The heats really needed to effect the bendings and the scarfing do not involve much injury to the quality of the metal, but this is by no means the case with the welding heat. As steel is heated from medium cherry red, its structure undergoes changes while the chemical constitution remains unaltered. It is the structure that has varied its condition. That is to say, steel is made up of grains or crystals which may or may not have an intervening film between them. These grains begin to grow as the temperature rises above medium cherry red. Apparently, there is no stopping point until the metal is about to melt or does melt.

If the heat is stopped at any point above the medium cherry red, the grains will cease to grow. But unfortunately, they will not return to their original and normal size. I say "unfortunately," because large grains are an accompaniment of deteriorated quality. Enlarged grains mean reduced strength. If we want the original quality and strength, we must force or coax the grains to go back to normal size.

Fortunately, there are methods of doing this. One process depends upon working the metal. The forging hammer, the rolling mill, the draw bench, etc., are means which are more or less successful in breaking up big grains and inducing them to remain small. The second method accomplishes its results with less outward violence. It consists in heating up the metal again, beginning at a point below medium cherry red and proceeding to a point that varies with the character of the steel. The result is that the big grains break up and a re-formation takes place. The new size of grain will tend to approximate the size which corresponds to the temperature at which the heating is now stopped.

Both methods are good. However, in actual practice it is not always possible to make the blows of the hammer or other means of working the steel reach everywhere. Every part of the weld and the adjoining metal

that was highly heated will be damaged steel. To restore the quality with the hammer, the effects of the blows must reach all, and not merely some, of the damaged spots, inside and outside. There are parts of the weld where the hammering will generally be sufficient; but there are interior portions and regions distant from the weld where the smith may neglect or be unable to hammer.

If it is proposed to restore by hammering the quality of the metal in a link after it has been heated at the joint to 1900 or 2000 deg. F., let the smith bear in mind two things: (1) The restoration is not to be expected everywhere unless he hammers everywhere. The interior will not be restored unless the force of his blows penetrates to the interior. (2) The benefit will in large part be determined, probably, by the temperature at which he stops working the metal. For example, if he works the steel without let up from the incandescent welding heat down to, say, a full orange, the benefit will correspond to the grain size belonging to full orange or to a shade somewhat brighter.

In view of these two principles, the smith must work all over the region where there was high heat and make his blows penetrate; and he must keep all this going, down to a point near full cherry red. The reheating method is undoubtedly better, if for no other reason than that it is easy to make the restorative effects penetrate thoroughly. In fact, the thing to do is to deal with the chain as a whole and not with the individual links.

Proper Heating of Completed Chain

The chain when absolutely cold—or at least not hotter then, say, a black heat—is put into a heating compartment and heated up to the point appropriate to the particular steel in hand. It will be excellent practice to do the latter part of the heating slowly. The object is to get the heat to penetrate to the interior without raising the outside to too high a point.

After the proper temperature has been obtained, and the heat held steady for a time, the work may be left in the furnace and the whole allowed to cool off slowly together. If it is necessary or desirable to take the chain out, or if the weight and bulk of the furnace are not such as to guarantee the chain a slow cooling, the work may be withdrawn and heavily packed in some nonconductor of heat like slaked lime, dry ashes, dry sand, asbestos fiber or the like.

Perhaps the most difficult operation, if the steel happens to be a very soft metal, is to determine when to stop the rise of heat in the reheating procedure. It is not difficult, if the steel contains 0.40 or 0.50 per cent. carbon or some higher percentage, as in such a case the common horseshoe magnet may be used. But chains are often, not to say usually, made of steel containing less than 0.40 or 0.50 per cent. of carbon.

The proper stopping point for these steels is higher than that at which the magnet loses its grip. The less the carbon content, the higher is the stopping point. For steel having zero carbon, the terminal temperature has been given as somewhat above 1652 deg. F. (full orange). This is over 252 deg. above the magnetic point for such steel. For steel having about 0.50 per cent. carbon, the stopping point is somewhat above 1400 deg. (full cherry tending to light red). This is just above the magnetic point. Consequently, we have the rule: For steels varying from 0 to 0.50 per cent. carbon, the temperature which should be attained varies from 1652 to 1400 deg.; intermediate steels have proportionate temperatures just above which the heat should be halted.

As the total variation in temperature is 252 deg. and the total variation in carbon content is 0.50 per cent., for every 0.01 per cent. of carbon less than 0.50 per cent. we add 5 deg. of temperature to 1400 deg. Thus, for 0.20 per cent. carbon steel we have to deal with a carbon content 0.30 per cent. less than 0.50 per cent. As we are to allow 5 deg. of temperature for each 0.01 per cent. carbon less than 0.50, the total temperature change is $30 \times 5 = 150$ deg. The stopping point, accordingly, for 0.20 per cent. carbon steel is in excess of 1550 deg. (light red.) Seger cones or some equivalent may be used to determine the temperatures.

The warning must be given that for low carbon steels it will be best to use the foregoing figures as rough guides. Experimentation with the exact steel you have to work with may be necessary in order to get the best results. Commercial steels vary too much in respect to impurities to permit a total disregard of all experimentation.

Carbonization and Distillation of Peat

The value of peat lies in its distillation rather than its combustion, and on these lines it could supersede wood in the production of acetic acid, methylated spirits of ammonia and tar; the latter being the basis of so many dyes.

In the process of distillation, as peat is a light, bulky material, it requires larger retorts than coal, and of a design which facilitates the transmission of heat from the surface toward the center. Experiments have shown that revolving retorts produce the best results. The apparatus devised and here described is on the principle of the roasting appliances used for coffee, chicory, and so on, but of course with the addition of a receiver for collecting the distilled vapor; the great object being to provide apparatus complete in itself for continuous operation.

This apparatus consists of six cylindrical retorts, each mounted on its own axis and capable of uniform rotation; the individual rotating cylinders are arranged radially about a central pivot, so that the retorts charged with peat can be successively introduced into and withdrawn from a stationary semicircular furnace.

When the apparatus is in operation there are always three retorts in which peat is being distilled in the furnace; the other three being outside—one condensing, another emptying and the third recharging. The distillation takes on an average about 40 min. for retorts holding a ton of peat and making six revolutions per minute.

To enable the gas arising from the carbonized peat to pass out of the retorts, the hollow shaft of each is perforated so as to provide a passage from the inside of the retort to a collecting chamber in the axis of the pivot and thence to the stills for fractional distillation.

The rotary movement of the retorts insures rapid transmission of heat from the furnace to the retorts, and as this heat acts on a large surface, the peat is uniformly carbonized in a short time and at a relatively low temperature.

Coastwise Shipping Conditions in 1918

By G. G. WOLKINS
Boston, Mass.

SYNOPSIS — *Serious shortage of colliers followed by embarrassing surplus. A notable record. Difficulty of keeping ships manned. Problems for 1919. Rates on barge and sail tonnage.*

THE prominent feature of the first half year of 1918 in shipping was the great effort made to provide cargo space to meet New England's coal requirements. For the two months ended Jan. 19, 1918, an average of only 89,600 gross tons per week was loaded at Hampton Roads for New England, and the first three weeks in January it dropped to only 70,000 tons weekly. In the judgment of the trade the need was imperative for not less than 200,000 tons weekly from Hampton Roads and 25,000 tons weekly from Baltimore. The answer was—more ships. Clearly it was the lack of shipping, sold, taken in Government service, or abroad on atractive charters, that was the largest factor in the tense fuel situation that prevailed in January and February.

In March it was agreed by representatives of the Shipping Board and of the Fuel Administration that at that time, in addition to barge transportation, there were steamers available amounting in tons to 238,000 D. W. capacity. To these there was promised an addition in March of 32,575 D. W. tons, making the total 270,575 tons. But beyond this there would be required additional steamer tonnage of 170,500 to move the coal, figuring 27 trips from April to December, at that time estimated as necessary to keep New England going.

By June a lot of progress had been made. Not only were the "Achilles" and the "Ulysses," 12,500-ton Panama Railroad colliers, diverted for the emergency, but new Lake-built steamers of around 3000 tons capacity were added as fast as they could be brought around. Through March, April, May and June the situation had improved to such extent that twenty ships, aggregating 89,700 tons, were withdrawn. Most of them were old-type general cargo boats of neutral registry and were only put into the coastwise coal trade to meet the unusual situation.

During the week ended June 21, eight steamers, amounting to 26,544 tons, were added, so that at that time the steamers in operation, 78 in number, totaled 320,602 tons, to which should be added 16 steamers, or 68,910 tons, then repairing, to make up the aggregate of 389,512 tons in service—94 steamers in all.

The deficit in coal-carrying capacity was therefore being rapidly made up. In July, the week of the 13th, the highest number was reached. Besides twenty steamers, or 55,900 tons, on a contract basis, there were 132 steamers, or 342,000 tons, chartered trip by trip by the Shipping Board to carry coal to New England. To show the extent to which this tonnage was later reduced, because New England was getting jammed with coal, 38 steam colliers were withdrawn between Nov. 27 and Dec. 7. On the latter date but 16 ships, or 44,800 tons, were left that were not operating on a contract basis plus the twenty that were, or but 100,700 tons in all in service. At the end of the year there were steamers tied up in Portland and in Boston because no charters were offering. In one week in September colliers amounting to 90,000 tons were withdrawn for General Pershing's bridge of ships. It all forms a notable record of ebb and flow in tonnage available.

As to rates, there was the same uniformity on steamers taken over and operated by the Shipping Board as in 1917, when colliers above 2500 tons D. W. were commandeered. The rates named in December, 1917—$3 from Hampton Roads and $3.25 from Baltimore—to Boston was in effect until the week ended Apr. 13, when in each case there was an advance of 25c. This remained in force throughout the rest of the year.

The complete story of how the increased cargo space was obtained would make interesting reading, but it is practically inseparable from the same efforts to get coal. Coal and ships were bound up together the first half year, as indeed they were the second, although the process was reversed. The wooden steamers so much talked about early in 1918 had no chance to materialize in the coal trade. By the time any of them could be put into commission it was foreseen the emergency would be over.

Few Losses Due to U-Boat Activities

It was in May the statement was authorized that from then on there would be a steady flow of completed vessels from Lake yards. At one time there were 34 en route from lakes to seaboard. It was to avoid waste of transportation that several of these loaded Provincial coal at Sydney, C. B., a tonnage that was readily absorbed.

Submarine activities slowed up movement for short intervals, but naval intelligence service was good and very little tonnage was lost on that account. Had it not been for the delay in manning and keeping manned the new ships that came, the surplus in August would have been much more pronounced. The loss in efficiency was said to be at least 25 per cent. for this one reason. Steamers that had been counted on for 34 trips were at that time making barely one in three to four weeks. Time was when certain of the colliers made 47 trips a year. The problem of securing crews and keeping them aboard was a serious one all through 1918.

For 1919 there are many kindred problems. What is to be done with the surplus of high-cost ships? It is not possible to compete with foreign shipping under our existing laws. Conferences have been held, but as yet no real progress has been made. Steamship owners feel that shipping should be under private ownership. Are foreign nations to be induced to scale

up wages and other conditions to a level with ours? These are questions for 1919 to answer.

Barge rates to Long Island Sound, New York loading, during the second half year were fairly constant at the rates suggested by the Shipping Board—$1.90 to Providence, $2 to Fall River, $2.15 to New Bedford and $2.50 to Boston, in each case the rate applying only to anchorage.

On July 25 the Cape Cod Canal was taken over by the Railroad Administration under presidential proclamation. The proposal was to deepen to 25 ft. to make the canal available for barges and steamers of the type most in use.

Outside barge freights, Hampton Roads to Boston, for practically the entire year, were 25c. higher than steamer freights. A sailing vessel was chartered in the same trade at $4 in April. The rate on bituminous in Reading barges the second half year was $2.05 from Port Reading, N. J., to Boston points and $2.40 from Philadelphia. The range of freights from New York to eastern Maine points was $4@5. Seldom was there any surplus, so few in number are the craft that 25 years ago used to carry the great bulk of the coal to Maine ports.

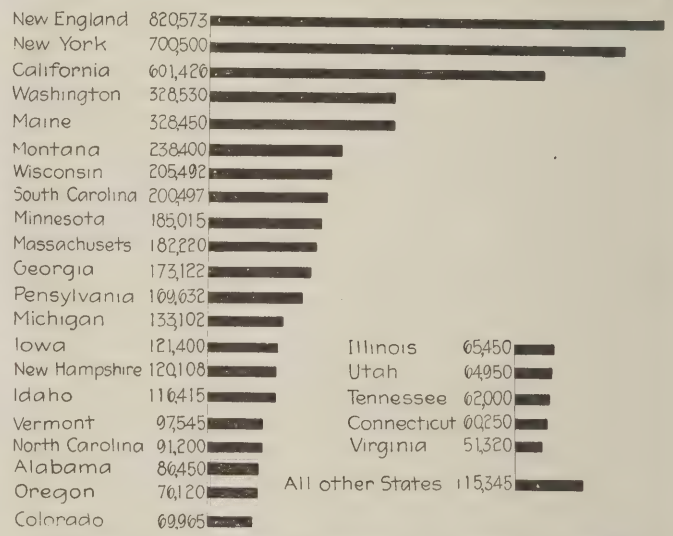
Coal Dumpings at Hampton Roads Piers in 1918

Notwithstanding the fact that coal movement was seriously hampered during the past winter by reason of extremely unfavorable weather conditions for the operation of coal piers and harbor craft, the movement of coal for the year 1918—reaching as it did in round figures over seventeen million tons—exceeded the quantity of coal moved during any previous similar period.

The demand for coal of all kinds has been heavy, especially so until the signing of the armistice. The lull which naturally occurred since that time is already changing into greater activity of coal movement. The outlook for Tidewater coal movement is encouraging—especially export business—and the coming year, 1919, should develop a still greater flow of coal through this Tidewater harbor.

COAL HANDLED AT HAMPTON ROADS PIERS DURING 1918

	N. & W. City Pier	N. & W. Lamberts Point	C. & O. Newport News	Virginian
January	20,488	338,842	283,790	235,736
February	25,407	533,876	436,971	329,369
March	23,818	628,737	500,870	379,641
April	25,140	650,511	501,056	365,781
May	26,036	751,486	457,902	422,810
June	23,882	680,670	438,160	392,763
July	25,009	810,891	493,402	402,029
August	19,784	796,743	461,709	377,383
September	20,076	679,342	442,692	403,350
October	24,311	663,177	383,120	316,851
November	20,973	545,696	302,637	323,974
December	.....	396,154	259,728	238,952
Totals	254,894	7,526,165	4,962,037	4,188,664
Grand total 1917				15,828,139
Grand total 1918				17,201,760



The figure 17,201,760 tons, reached in 1918, sets a high mark for the Hampton Roads piers, being 2,418,819 tons greater than last year and about two millions greater than 1916, which was the banner year for coal handling at the Norfolk and Newport News coal docks.

While it may be true that the great records made during the past year and the two preceding years were a result of war conditions, it is also true that the activity in the coal trade that has been created is obviously bound to remain. With the coming of peace and the renewal of unrestricted trading by merchantmen steamers, the coming year may see an even greater record hung up than during the year 1918.

France, Italy and the other nations of Europe have been for four years suffering keenly from a lack of coal, and before operations can be fully resumed in the mines of Europe all the coal that can be mined and shipped in from the United States will find a market.

Great Increase in Water-Power Development Where Coal Is High in Price

The accompanying chart shows the water-power development of this country up to 1914. Small plants or those generating less than 1000 hp. each are not included. It will be noticed at once that the greatest development has taken place in the Northeast and the extreme western portions of the country; or, in other words, in the regions where coal is necessarily high in price on account of long freight hauls.

WATER-POWER DEVELOPMENT IN UNITED STATES

Many sources of water-power are still undeveloped. The next decade will doubtless see much activity in this direction. The overhead charges on water-power plants are high, and as a rule considerable time is required to build one. When power is wanted quickly, therefore, a steam plant may be constructed with much more dispatch than a hydro-power plant. War time has therefore been unfavorable to the development of water-power. Peace, with its decreased industrial stress and its anticipated lower costs of labor and materials, should tend to stimulate such development.

Campbell states in a report of the United States Geological Survey that the coal reserves of the world, in short tons, are as follows:

Americas, 5,627,823,500,000; Asia, 1,410,487,600,000; Europe, 864,412,600,000; Oceania, 187,842,900,000; Africa, 63,755,900,000; a total of 8,154,322,500,000 net tons. The United States has 4,205,154,000,000 net tons, or over half the total of the world reserves.

High Lights in the Coal Trade During the War Period

By ALEX MOSS
Editorial Staff, *Coal Age*

TO FAITHFULLY chronicle the happenings in the coal industry during the war period would be a task of no mean proportions, and it is not the intention of the writer to enter into the subject *ad exhaustum*. To do so would result in a volume that would compare favorably in size with "Webster's Unabridged." The milestones, as it were, that marked the road traveled by the coal industry while the nation was at war will be indicated, though the vast extent of ground lying beween, must, in the interests of space and the reader's patience, be left untouched for some more earnest and conscientious historian.

ON APR. 6, 1917, the United States entered the world war. Soon after we shelved the Monroe Doctrine and war industries began to get under way, a shortage of bituminous coal made itself evident. Anthracite was already scarce, though a true knowledge of the importance of this situation was confined to the trade. In spite of the fact, however, that stocks of soft coal in the hands of dealers and consumers were not large, there was little attempt being made at this time to accumulate reserves. The trade situation was somewhat confusing, there being a decided tendency of both buyers and sellers to await developments. Everybody was marking time and expecting some more definite assurance as to the future.

In official Washington it was early recognized that fuel was the very heart of the nation's life; and that in order to meet the greatly augmented domestic and industrial requirements, and to avoid the pitfalls into which France and Great Britain had fallen soon after the outbreak of the war, it was necessary to utilize or to create some force that would exert a sort of centralized control over the coal industry. This belief that the regulation of production and distribution of coal would serve as an excellent war measure found outcome in the formation in May, 1917, of a Fuel Board, with Francis S. Peabody as chairman. Mr. Peabody was a practical coal man and had gained recognition as an able organizer.

Fuel Board Settles Down to Business

Soon after the formation of the board a number of plans were set afoot looking toward the stabilizing of coal prices, the collecting of production statistics, and the efficient transporting and distributing of coal. The Fuel Board acted as a sort of clearing house, the members of the board being kept busy digesting and collating the vast mass of information needed to successfully work out the tremendous problems of the fuel situation. In June, 1917, labor was given representation on the board, and the way was thereby smoothed for more efficient coöperation between that body and the mine workers of the country.

Keenly desirous of efficiently handling the coal situation, the Federal Trade Commission, through the Fuel Board, made several rather startling recommendations—startling because no such drastic prescriptions were expected. In essence, the most important of these recommendations were as follows:

First, a pooling arrangement, which was to be placed in the hands of a Government agency, to control the production and distribution of coal and coke. The producers of the various grades of fuel were to be paid their full cost of production plus a uniform profit per ton (with due allowance for quality of product and efficiency of service).

Second, the transportation agencies of the United States, both rail and water, were to be similarly pooled and operated on Government account, under direction of the President, and all such means were to be operated as a unit. The owning corporations were to be paid a just and fair compensation, which would cover normal net profit, upkeep and betterments.

Reduced Current Prices of Soft Coal

In the latter part of June, 1917, after conferences had been held with the operators, the Fuel Board (now known as the Committee on Coal Production) made sweeping reductions in the current prices of bituminous coal. This was a revolutionary procedure, and, like other measures meant for the public good, it was received with much abuse.

Early in the conferences referred to above, it was realized that a national organization of coal operators would be necessary to make the price-fixing and other plans of the Government readily operable. To this end was formed a tentative organization composed of the twenty-five secretaries of coal-trade associations who were present at the sessions. C. P. White, of Cleveland, was chosen chairman and C. E. Lesher, of the U. S. Geological Survey, was made secretary. The association was to work in conjunction with Mr. Peabody's committee and was to be supported by an assessment, not to exceed ¼ mill per ton, to be levied on all operating coal companies in the United States.

In the meantime, the consumption of fuel was expanding to unprecedented proportions. Anthracite was still short (this condition proved chronic), though recourse to the culm banks resulted in quite large tonnages being sent to market.

Aug. 1, 1917, saw the tidewater pooling arrangement, suggested by the Committee on Coal Production, in full operation. All shippers of tidewater bituminous coal had agreed to pool their output at the ports of New York, Philadelphia, Baltimore and Hampton Roads, and time has proved that the benefits expected to be derived from this arrangement have been more than realized. This plan, too, came in for a bit of healthy criticism, many in the industry pointing out that there were obstacles that could not be surmounted, such as proper classification, just remuneration for carefully prepared coal, and matters of a kindred nature.

The maximum prices that had been announced by the Committee on Coal Production brought forth some acrid remarks from Secretary of War Baker, who characterized the new figures as "exorbitant, unjust and oppressive." But in spite of the disagreement between Government officials, the prices fixed were closely observed by the operators. True, all the available output was covered by contract, or some form of tentative agreement, but there was only a minimum business being negotiated under the Government's figures.

However, the prices of the Committee on Coal Production were short-lived, for on Aug. 21, 1917, President Wilson took the matter of price-fixing into his own hands and prescribed provisional prices to cover all the coal-producing districts in the country. The new figures were one-third lower than those agreed upon voluntarily by the operators with Mr. Peabody. The statement announcing the new prices divulged the information that they were based upon the actual cost of production and were deemed to be not only fair and just, but liberal as well. Provision was made for a reconsideration "when the whole method of administering the fuel supplies of the country shall have been satisfactorily organized and put into operation."

The market reacted to this new phase of the coal situation by "playing 'possum." All the coal operators in the United States were called upon by the Board of Directors of the National Association of Coal Operators to meet Aug. 29 at Pittsburgh, to discuss the latest pronunciamento.

Following upon the heels of the President's announcement fixing bituminous prices, came the setting of prices for anthracite, the specification of jobbers' margins—and the naming of a coal administrator. In a brief fifty-word statement the President made public the fact that in accordance with an act of Congress approved Aug. 10, 1917, he had appointed Harry A. Garfield, president of Williams College, as his fully empowered representative to carry out the provisions with regard to the control of fuel.

Relief Felt at Dr. Garfield's Appointment

For some days previous to the issuance of this pronouncement, it had been known in official circles that the President had declined to name a board of three to exercise control over the coal industry, and that a dictator was to be named. The name of the man most likely to be selected for the post was well guarded by the President, although Mr. Garfield's name did enter into the speculation a few days prior to his appointment. It may be said with all truthfulness that great relief was felt when Dr. Garfield's appointment was announced, as some had feared the selection of a man with less balance and more radical tendencies.

The new schedule of prices had no effect whatever on anthracite, though it threw the bituminous market into chaos. Practically all soft coal disappeared from the market, and delegations from all parts of the country rushed to Washington in an endeavor to get the prices on bituminous coal increased. Dealers who had purchased stocks of coal at prices considerably above the latest Government figures were in a quandary, for to dispose of their supply at the new prices would mean that many of them would suffer a considerable financial loss.

On Sept. 8, 1917, Dr. Garfield made public his plans for controlling retail prices by the formation of local fuel administrators in every coal-consuming section of the country. Shortly after this, intimations came from Washington that the President's provisional prices for bituminous coal would be increased, as in effect the original schedule had tended to decrease production.

In the fall of 1917 the publicity department of the Fuel Administration began to warm up to its work, and soon every man, woman and child who could read the newspapers knew that there was going to be a fuel shortage. Economy was preached to both domestic and industrial consumers, and industries that were not essential to the winning of the war began to get apprehensive as to their coal supply.

On Sept. 30, 1917, Dr. Garfield issued an order describing the method by which retail coal and coke dealers were to fix their maximum margin of profit. The order became effective the next day and authorized retail dealers to charge 30 per cent. above their 1915 margins.

Demands for Coal Exceeded Supply

All through the fall the demand for both anthracite and bituminous coal kept considerably ahead of the supply, and many sections of the country were in dire straits for want of soft coal. The price of bituminous had been increased 45c. on Oct. 27, the advance being made to cover the increases in the miners' wage scale that had gone into effect.

By December, 1917, it was palpably evident to those in the coal industry that the Fuel Administration would brook no interference with its plans. The personnel of the administration had been growing since its inception, and some of the best executive brains in the country had responded to Dr. Garfield's call and were giving a million dollars' worth of service for a dollar a year.

With the arrival of cold weather and the unprecedented temperatures that prevailed during the winter of 1917-18, came more urgent demands for coal from all classes of consumers. New England in particular was in a sorry plight, and large cities such as New York could get no hard coal to warm the homes. The tremendous amount of tonnage which the railroads were called upon to handle congested the yards and terminals, and overtaxed the motive power facilities so that it became impossible for the roads to handle expeditiously the most vital necessities. Embargo followed embargo, and preferential shipment orders for this and that helped to further muddle the transportation situation.

It can readily be perceived that the railroad congestion did not help fuel matters any. In fact, Dr. Garfield went on record as saying that the question of an adequate or inadequate coal production depended in large measure upon how soon the transportation difficulties were overcome. Every operation reported a shortage of cars, and though the clamor for relief was loud and long, no one seemed to know just what steps to take to ameliorate this condition.

So the fuel problem was tackled from another angle—that of conservation. Estimates made by the fuel authorities had determined that the country was be-

hind over fifty million net tons of bituminous coal. As there seemed to be little likelihood of output ever catching up with demand, reliance was placed in securing less waste of coal in large plants and in cutting down unnecessary uses of power. What the conservation department of the Fuel Administration accomplished in the next few months proved a revelation. And, if the country gained nothing else during Dr. Garfield's regime, it could still point with pride and profit to the lessons learned by industry in the elimination of waste brought about by improper firing methods, faulty boiler-room installations and other chronic fuel-wasting conditions.

As a climax to Dr. Garfield's statement that the railroads were chiefly responsible for the deplorable coal situation came the news that the Government had taken over the railroads. This astounding information was announced by the President in a proclamation issued on the night of Dec. 26, 1917.

The ushering in of 1918 found the country in the grip of an intense cold. The production and distribution of coal were proceeding as rapidly as transportation facilities would permit, though not anywhere near fast enough to satisfy the demand. The various local fuel administrations, boards and committees were perfecting their organizations, and the efforts to relieve congestion on the railroads were beginning to bear fruit in the shape of a slight improvement in the car supply at the mines.

"Workless Monday" Order in Effect

On Jan. 16, 1918, came the now famous Garfield order shutting down business for five days and closing up industries on every Monday until Mar. 25. The storm aroused by this latest announcement was far more tempestuous than any that had greeted other revolutionary edicts of the Fuel Administrator. Nobody had received any advance notice of the order, and following its publication the Senate of the United States permitted itself to reach a degree of excitement that could show few precedents. The political side of the situation received a thorough ventilation on the floor of the Senate, and only 19 votes were cast against a resolution introduced by Senator Hitchcock requesting a five-day suspension of the order to allow those opposing it to be heard. Nevertheless the order was obeyed with a promptness that clearly portrayed the temper of the American people.

February, 1918, brought a cold wave that greatly interfered with railroad transportation and served to negative much of the good work that had been accomplish up to that time. Throughout the New England States the fuel situation was still acute, both as regards domestic and industrial consumers. From many sections came reports of plants that were forced to shut down for lack of fuel, while many other concerns were enabled to keep running on a hand-to-mouth basis through special shipments of fuel by the local fuel administrators.

On Feb. 13 the order providing for heatless and workless Mondays was suspended. Though it was admitted that little coal had been saved by the order, it was generally acknowledged that it helped considerably to relieve the freight congestion.

Warmer weather during February brought a generally better feeling, which was reflected in a let-up in the urgent demand for domestic fuel. There was still a great scarcity of steam grades, and cities in the interior of the country were in a bad way for coal, principally anthracite.

Along in March the country began to stop worrying about its immediate coal needs and started to lay plans for future requirements. Even the situation in New England showed signs of improvement. Much of the freight congestion had been cleared away by this time, though the bituminous operators still complained bitterly of a car shortage that hampered their efforts at increasing production.

With the drawing near of the new coal year, operators, jobbers, dealers and the consuming public relaxed from the tension of a nerve-racking winter and turned their eyes toward Washington, whence had come whisperings of new plans for prices, zoning, car supply, diversion of shipments and so forth.

Anthracite Coal Situation Unimproved

The demand for coal continued to exceed the supply in virtually all grades. A slight betterment was evident in the production of bituminous coal, owing to an improvement in the placing of cars at the mines. Anthracite, however, continued to be scarce, and there was no reason for believing that this condition would change.

After months of work, the Fuel Administrator on Mar. 22 announced a zoning plan for the distribution of coal. This was to go into effect Apr. 1. Every state in the Union was more or less affected by the plan. The basic idea underlying the new move was to confine Eastern coal to Eastern markets and make it compulsory for the Middle West, as well as other sections, to use coal produced in near-by mines. The announcement was received by the industry with commingled feelings. Many operators and shippers who had been years in building up trade connections suddenly found their customers taken from them. Consumers who had been accustomed to burning certain qualities or grades of coal were forced to use fuels with which they were less familiar. *Mais, c'est la guerre,* and producers and consumers alike readjusted their old methods of doing business to conform to the new order of things.

The trade was still further convinced that the Fuel Administration had control of the entire coal output, from the time it left the mines till it reached the consumer's bin, and even the furnace, when Dr. Garfield on Apr. 1 announced that all coal jobbers would have to procure a license in order to continue in business. Many abuses had crept into existence which the Government desired to eliminate, and the licensing plan, stated Dr. Garfield, would be fair to the operator, fair to the bona fide jobber, and fair to the consumer. The new system was somewhat of an innovation, for it enabled the retailer, for the first time, to buy at his option of the producer or the jobber.

By the beginning of the new coal year the Fuel Administration had made rapid progress in the task of clearing the path for a quick movement of coal from mine to consumer. New prices had been announced, the local fuel administrations had perfected their organization to take care of distribution—but there was no coal. No improvement could be reported from the

bituminous mines. In many producing districts the car supply was still below normal, and not sufficient motive power was available on the railroads to clear the yards promptly enough to insure the regular movement of cars. The trade at this time was somewhat uncertain, owing to the fact that the making of contracts for the new year was confounded by Government commandeering and preferential shipment orders.

During April the output of hard coal began to increase, though the operators had to contend with a shortage of labor that grew more serious as the months went by. Bituminous coal output, on the contrary (it always is "on the contrary" when hard and soft coal conditions are compared), continued to be disappointing. The railroads had shown no improvement in the manner in which empty coal cars were allotted, and John Skelton Williams, who was in charge of purchases for the railroads, insisted on the right of the roads to distribute cars where and how they pleased. There was an ulterior motive behind this attitude, which was to use such control of shipping facilities as the railroads possessed for the purpose of forcing price concessions from the coal producers. Thus was the public confronted by the amazing spectacle of one branch of the Government setting at naught the edicts and rulings of another Government body. This action on the part of the Railroad Administration served as did nothing else to bring to the support of Dr. Garfield many of the operators who had hitherto been inimical to him.

Better Feeling with Warm Weather

With the sunny skies and warmer weather of May came a feeling of optimism. Recognizing the truism that the public is prone to forget what it had suffered in the past, the fuel authorities began to urge consumers to lay in their coal supply during the summer months, and not to wait until winter was again upon them. The production of both anthracite and bituminous coal was steadily increasing in the meantime, though inadequate car supply still hampered a maximum output of the latter.

A reduction of 10c. per ton in the mine price of bituminous coal on May 25, and an order that all consumers were to pay the same price for fuel, settled the long-standing controversy between the fuel and railroad administrations. Immediately following this order the railroads began to take a large tonnage of coal.

Industries deemed unessential to the winning of the war were being denied the use of any kind of coal when June arrived, while dealers in anthracite were unable to fill even the two-thirds requirements of all their domestic customers.

Gradually the truth was borne in upon interested parties that the coal industry was being organized as it never was organized before. Many there were who believed that the production and distribution of the nation's entire coal output could not be systematized, but the Fuel Administration staff, under Dr. Garfield, was accomplishing the seemingly impossible. Weekly reports made to the Fuel Administrator kept him conversant with the actual output and consumption of coal in each zone, and in this way a watch was maintained on the needs of each section. In many instances where the occasion manifested itself, coal was shifted in transit to take care of emergency cases. Quotas had been fixed for those cities that were permitted to burn anthracite, and none of this grade of fuel was to be sent west of the Mississippi or south of the Potomac or Ohio rivers.

During all the foregoing period bituminous coal had been in such urgent demand that much of it got to market as it never got to market before. Some of the fuel was good, far too great a quantity was bad, and a whole lot of it was indifferent. To correct this evil, and to insure that the consumer who paid for coal would get what he paid for, Dr. Garfield on June 1 made public new regulations that imposed heavy penalties on operators who persisted in shipping dirty coal. To enforce these regulations inspectors were appointed for the different bituminous-producing sections.

Attempt Made to Speed Up Production

It became evident at about this time that one of the things essential to a solution of the bituminous coal problem was to speed up production. Having established this fact, Dr. Garfield formed a new section of the Fuel Administration, to be known as the Production Bureau, and placed the difficult task of stimulating the soft-coal miners to greater endeavors in the hands of James B. Neale, who had been acting as his advisor.

July found the coal industry hard and fast in the grip of Governmental regulation and administration. The competitive features that had distinguished the coal market in previous years were conspicuous by their absence, and one said it all, in referring to trade conditions, when he stated that "Demands for all kinds of coal are urgent, with stocks inadequate." The railroads and the fuel authorities were working together shoulder to shoulder, and the bituminous mines were producing record tonnages. Many of the larger operators at this time were shipping their entire output to the lakes, but because of the late opening of navigation shipments to the Northwest were behind schedule.

During the month of July record outputs of soft coal were made in many districts. But so rapidly did demands increase, that the manner in which industry was literally swallowing the nation's production of bituminous coal was being viewed with consternation by the Federal Fuel Administration. Every week that passed brought a new or additional requirement that had not been foreseen, and therefore not included in preceding estimates. For instance, a call for coal to be used in France and another to take care of an English obligation in Chile were typical of the latest types of demand of which no previous calculation had been made.

Naturally, the production and conservation divisions of the Fuel Administration were exerting their utmost efforts to help stem the overwhelming tide of demands. Car supply at the mines was good, in some few cases equaling or even exceeding requirements, and a shortage of labor began to manifest itself in the soft-coal regions.

In August the Department of Labor classified coal mining as war work, and efforts were made to keep the mining forces from leaving their tasks for other war industries such as munitions plants and shipyards, where higher wages prevailed than in the mining districts. Throughout the West and Middle West produc-

tion was well up to the demand, and reports began to circulate that certain grades and sizes of Indiana and Illinois coal were being sold below the Government maximum. In the East, however, particularly along the Atlantic seaboard, demand for all grades of coal was strong and dealers were unable to accumulate any stocks, except of the smaller sizes of anthracite. The movement of coal to the lakes was heavy, though receipts at the upper lake docks were still behind the schedule. Every effort was being made to keep shipments to the Northwest by water at a maximum, as only in this way could that region be taken care of by the close of navigation.

The intense heat during the middle of August exerted an influence more or less potent upon the production and distribution of coal. Reports at this time, however, failed to reveal any shortage of coal for immediate needs. Some regions had been able to accumulate surplus stocks in fair volume, while others were unable to build up any reserves whatever.

The condition of the country, so far as concerns coal, on Aug. 20 was about as follows: That portion of the country lying roughly between the Rocky and Allegheny Mountains appeared to be fairly well supplied with fuel, though Michigan was complaining of a shortage of domestic coal. A scarcity of coal seemed to be most pronounced along either coast. New England, while admitting that coal was coming forward in adequate volume for immediate needs, nevertheless was still apprehensive as to the future. On the Pacific Coast industries were somewhat short of coal; and although little anxiety was felt, it was anticipated that wood and other fuels would have to be used during the winter.

Opinion Divided as to Future

By the middle of September conjectures as to the outcome of the fuel situation were many, but only one gifted with infiinite knowledge could prophesy at that time, with any degree of accuracy, how the country would fare during the approaching winter. Optimists pointed out that the storage rules prescribing the quantity of coal that could be kept in reserve by industries in certain sections, the modifications of zone restrictions, the large stocks in the hands of consumers, and the improved car supply at the mines were all happy auguries. Pessimists shook their heads sadly as they compared the weekly tonnage figures with the estimated requirements, and heaved a heartfelt sigh at the news of labor troubles at the mines. They argued that the consistent preaching and enforcing of conservation measures were certain indications of a stressful winter.

A strike in the anthracite region during September caused quite a drop in output. The hard-coal miners, after maintaining an enviable record for patriotism and production, struck for higher wages in the face of an existing contract and the country's needs, and many collieries were forced to suspend. In many towns hundreds and thousands of orders for hard coal were on the dealers' files, and it was believed that there would be a duplication of the suffering of the preceding winter if cold weather were experienced.

In the meantime every red-blooded American was being thrilled with the accounts of the heroic exploits of our boys across the sea. The Fuel Administration had placed the question of whether the miners would back up the achievements of our forces with an increased production of coal squarely up to the workers themselves; it was either plenty of American coal or the loss of American lives.

The coming of colder weather in October witnessed an urgent demand for fuel from household consumers, an influenza epidemic from which the country was suffering causing the starting of fires in homes much earlier than usual. The stove and chestnut sizes of anthracite were in strong demand, though an outstanding feature of the market at this time was the collapse in the demand for the steam sizes of hard coal, several collieries being reported as about to close down for lack of orders.

Fuel Administration Justifies Itself

By the middle of October even the most carping critic was forced to admit that the Fuel Administration had amply justified its reason for being. In control of all production and distribution facilities, the administration had brought to fruition the many plans which it had formulated early in the year for safeguarding the nation's fuel supply. In the face of apparently insurmountable obstacles and scathing sarcasm from many quarters Dr. Garfield and his assistant had labored steadily until chaos had given way to order. New England and a number of other important industrial centers had ample reserve stocks of fuel against the uncertainties of winter mining and shipping conditions, the exact reverse of what was true in the fall of 1917. The Northwest, too, had been amply taken care of, and it was a foregone conclusion that the lake shipments would meet the schedule.

And then came peace talk and influenza to trouble the coal-mining industry. Premature reports of the surrender of Germany led many mine workers, among millions of others, to throw down their tools and enter into an orgy of celebration, with the result that the coal output was reduced. More serious, however, during the latter part of October was the havoc being wrought by the influenza epidemic, particularly in the hard-coal regions.

The belief was strong in late October that there would be no serious shortage of bituminous coal during the winter of 1918-19. The needs of essential industries were being supplied as they became evident, and even nonessential industries were being permitted to accumulate reserve stocks under a new order issued by the Fuel Administration. Anthracite coal still continued to present a problem, though the prevalence of warm weather kept consumption down. Furthermore, there was every reason for believing that the bins of domestic consumers were stocked with coal as never before.

With the urgent need for quantity production of soft coal now somewhat ameliorated, the Fuel Administration again began to turn its attention to quality. During the week ended Oct. 28 orders were issued to a number of soft-coal mines prohibiting them from mining or shipping their product, as it was of an inferior quality. This made a total of 99 mines closed since the Fuel Administration inaugurated its campaign for clean coal.

Early in November a surplus of soft coal was reported from practically all mines west of Pittsburgh, this

unusual condition being attributable largely to the possibility of an early sure-enough peace, and partly to the exceptionally mild weather prevailing throughout the country. Developments in the war situation changed with such rapidity that manufacturers of war goods stopped buying coal, as it was evident that if Germany accepted the terms of the Allies' armistice, war work would cease.

Then the expected happened, though much sooner than had been looked for. On Nov. 11, 1918, about 19 months after our entry into the conflict, the world war came to an end. Demand for soft coal was cut off as with a knife. Immediately consumers discovered that they had a large oversupply of coal on hand, and mines that only a short time before were hard put to it to meet their production quota found that they were unable to dispose of their output. Bituminous coal of the lower grades became a drug on the market, and bituminous operators one after the other were forced to a realization that for the present their days of prosperity were over. What the story would be in the future, when the country readjusted itself to a peace basis, was open to conjecture. But one thing was evident. Until industry again began to go full steam, the bituminous mines would have to mark time.

Efficient Storage of Explosives

By C. Atwood
Tamaqua, Penn.

The watchword of "efficiency" has taken a sweeping hold on the people of the country during the past two years. Greater efficiency was planned for manufacturing plants, was put into play on the farms, entered the homes of our people and found its way into the mines. As a result enormous amounts of coal were poured forth from the shafts each day. There was, however, a place in some mines where efficiency was neglected, and that was where the high explosives were stored.

Moist storage conditions work a great deal of damage to powder and for this reason the best of drainage possible about a magazine should prevail at all times—everything should be done to keep excessive moisture from the magazine. Some magazines are so poorly arranged in regard to drainage that after a rainstorm great pools of water can be seen standing on the floor about the cases of dynamite. Even though the water does not come in contact with the boxes of explosives (though oftentimes it does), the water evaporates and makes the air humid. When repeated two or three times the humidity becomes so excessive as to cause the powder to become soft and mushy in the cartridges. Where the cases of dynamite stand in puddles of water for any length of time, some of the ingredients may possibly be dissolved out. While dynamite in any of the above-mentioned conditions may shoot, it is almost certain that it has lost some of its efficiency and may cause misfires. Misfires are expensive and also dangerous, and should be carefully guarded against wherever possible; even if the dynamite detonates, it is quite possible that it may have lost some of its strength by the dissolving out of some of its ingredients. It may also give off obnoxious fumes for the same reason.

Excessively hot storage may also cause trouble with powder. Of course not many mines are afflicted with this fault, but yet there are some which are, and it is just as much a fault as a damp magazine. Continued heat in time has a tendency to make a powder unstable and it also causes it to leak and get soft and mushy, as when it is stored in damp places. It is well known that permissible powders contain enough moisture in them in some form or another to cool the flame and thereby make the powder safe in dusty or gaseous mines. A hot magazine tends to dry out this moisture, and this may reduce the safety of the explosives if they are kept in heated storage for a long time. Some types of dynamite after being kept in a hot magazine get very hard when they are taken out to a place where the temperature is cooler, so hard in some cases that it is difficult to insert a cap in them. Should this difficulty appear, it can be easily overcome by rolling the cartridge by hand on a flat wooden surface until the powder becomes soft. After this the cap can be inserted easily.

One of the worst types of magazine is the one that is damp, hot and has poor ventilation. Here we have a heated, humid atmosphere, and with poor ventilation there is no means of changing the air. This warm, moist air, held in contact with the powder for days at a time, readily dissolves out ingredients from the dynamite due to the increased solubility of salts with an increase of temperature. With this condition we have a damaged powder whose properties are not the same as when it was received at the mines. In other words, we have a powder which has been lowered in efficiency and will not do the work that it would have done when it first reached the mine.

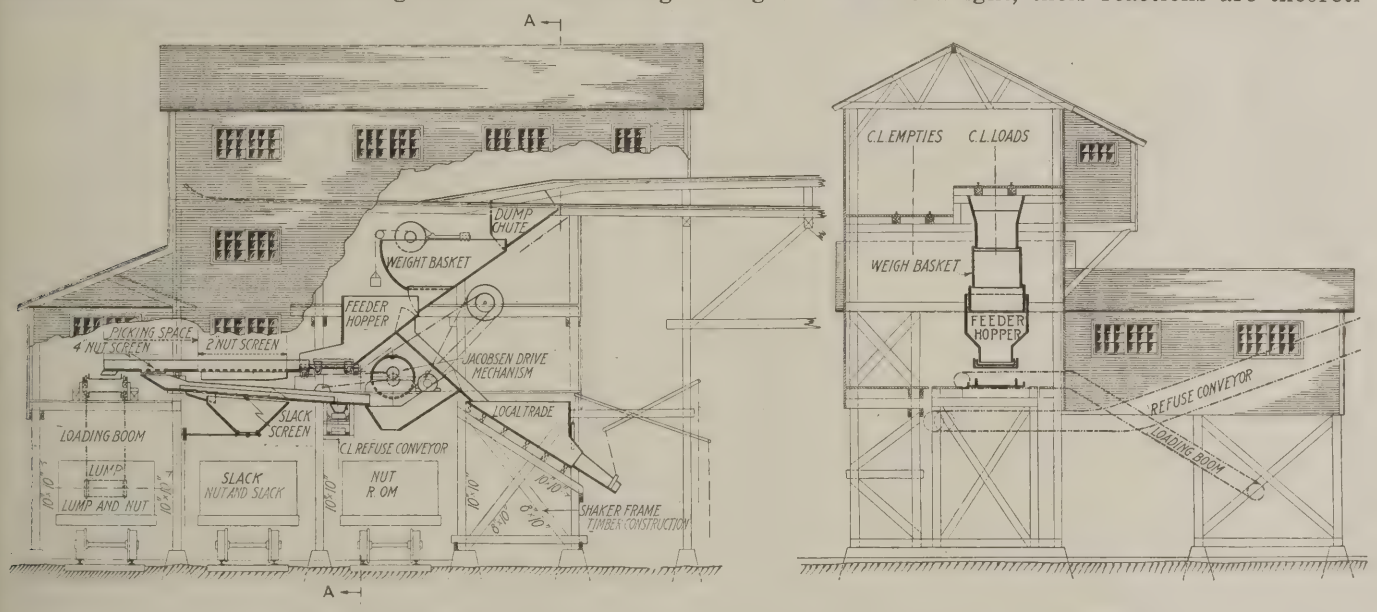
One of the common faults of magazines is cold storage. It is difficult to say whether this is a worse fault than a damp or hot magazine. But it certainly is a serious one, and one that it would pay to remedy. Of course, an extremely cold magazine means frozen dynamite, and frozen dynamite is treacherous. Before it can be used it has to be thawed, and because of careless methods used by some miners thawing is dangerous; the liability to accidents is great. At times, when a miner is in a hurry, the stick may be only partly thawed and still have frozen spots in it. Frozen powder is more sensitive than unfrozen, and frozen spots throughout a partly thawed stick may cause trouble. It may be set off by friction on the side of the hole or by a metal tamper; friction caused by breaking the powder in the place where it is frozen may be enough to start a detonation. Partly thawed powder may cause a misfire or only a partial detonation. All of the above-mentioned results from a partly thawed cartridge are serious and should be watched carefully. A powder that is much chilled and yet not frozen is cut down in efficiency; it lowers the sensitiveness of the explosive and it also lowers its brisance; that is, it cuts down its shattering power.

It can easily be seen that efficient storage is a matter that should be observed much more carefully around mines. Better powder, greater production and more safety for the miner are obtained. In order to procure this, magazines should be kept dry and at a normal temperature (between 60 or 70 deg. F.), and in this manner a greater good will come to all, miners and mine owners alike.

Modern Tipple Equipped with a Simple Balanced Horizontal Screen

By FRANK J. SCHRAEDER
Chicago, Ill.

SYNOPSIS—*A small wooden tipple of large capacity is here described. The screens are double-decked, horizontal, with opposed and balanced movement. This balancing permits the supporting frame to be of comparatively light and inexpensive construction.*



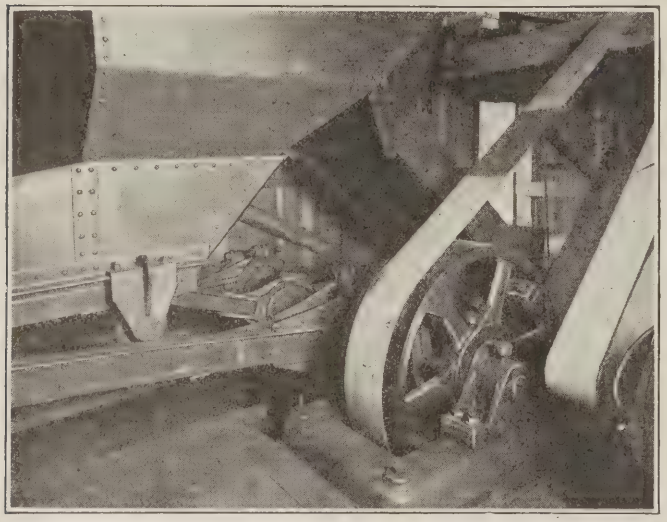
DURING the last two years almost anything that was black sold as coal, and under the emergency there was a ready market for it. However, almost immediately upon acceptance by Germany of the armistice terms, the demand for clean, well-sized coal increased, so that today many operators are interested in and planning for the installation of a simple equipment for the preparation of their output.

Some operators foresaw this and equipped their mines to meet the new conditions arising after the war. Among these, the Van Kirk-Carroll Coal Co. has recently put into operation a new tipple for its mine at Dellroy, Ohio. The equipment there installed is considered the simplest modern tipple machinery for screening, picking and loading coal.

The equipment and its arrangement are indeed remarkably simple. There is comparatively little machinery and less equipment than has heretofore been required for the work and results afforded. Nothing has been sacrificed in the way of advantages, but instead the efficiency in screening has increased and the number of mechanical units has been decreased. For illustration, a single drive with a single motor actuates the self-cleaning reciprocating feeder, the combined screen and picking table, and refuse conveyor.

In the Dellroy tipple shown in the accompanying illustrations, coal is brought to the tipple in trips of 10 to 15 cars each. These are passed over a Phillips crossover dump and discharged into a weigh basket especially designed to receive the coal without breakage. After weighing, the coal is carefully passed from the weigh basket into the feeder hopper. Both basket and hopper are large enough to hold two mine cars full of coal, in order to facilitate quick dumping. From the feeder hopper the coal is conveyed at a uniform rate of 100 to 150 tons per hour to a pair of Jacobsen balanced horizontal shaker screens, which are 4 ft. wide, and arranged for loading on three tracks.

The screens consist of one upper deck, adapted to convey the coal forward toward the lump track, and a lower deck, adapted to convey the coal and refuse pickings in the opposite direction. The two screens travel in opposite directions at identical speeds, and being of the same weight, their reactions are theoretically completely counteracted, thereby eliminating the necessity of heavy, reinforced concrete supports or any heavy structure. In this particular case only a simple wooden frame was employed to support the drive.



SECTIONAL ELEVATION SECTION A-A

SECTIONAL ELEVATIONS OF THE DELLROY TIPPLE OF THE VAN KIRK-CARROLL COAL CO.

The upper screen is provided at the receiving end with 8 ft. of 2-in. circular perforations and at the delivery end with a short section of 4-in. perforations; the intermediate part of the trough is provided with blank plates over which the 2-in. lump, which has been relieved of slack after passing over the 2-in. perforations, is conveyed in a thin, uniform layer. This makes each piece of refuse clearly visible, so that picking may be performed directly on this upper screen without the installation of a separate picking table. The coal, after having been picked, passes over the 4-in. perforations,

the over-size being conveyed over the end of the screen and delivered without breakage to an apron type of loading boom. The 2-in. to 4-in. nut passing through the 4-in. perforations to the lower screen joins with the 2-in. slack and passes over 10 ft. of lip screen. The slack passing through the lip screen is delivered to a gate-

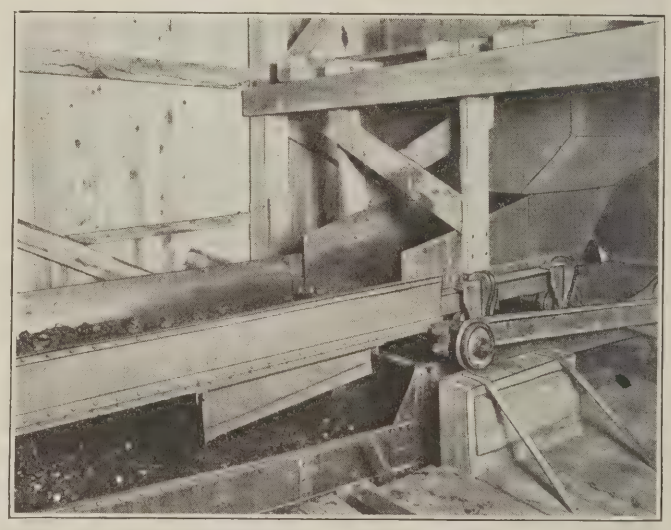
DRIVING MECHANISM FOR DOUBLE DECKED SCREEN

controlled hopper, whence it is discharged to the railroad car, while the nut coal is conveyed further and discharged over a chute to the nut track.

The refuse and pickings are deposited into two narrow troughs, there being one on each side of the lower deck. These refuse troughs are fastened direct to the lower screen and therefore receive the same conveying action without any additional machinery. Thus the refuse is separately conveyed in these side troughs and delivered to a scraper conveyor which carries it to a 50-ton refuse bin, where the sulphur and refuse are separated and from which they are loaded by gravity into railroad cars for shipment. This simple arrangement for conveying refuse on the side troughs of the lower screen will be appreciated, since this arrangement eliminates a refuse conveyor and its driving machinery.

The lump loading boom is 42 in. wide, of the apron conveyor type, driven by a 7½-hp. motor, and arranged for lowering and raising by means of a worm-driven winch operated directly by the drive machinery of the boom. Clutches are provided for raising and lowering the hinged section and for stopping the boom independently. These clutches are operated and controlled by rope from the trimmer's platform.

The driving head for imparting the reciprocating motion to the screens is known as the No. 4 Jacobsen driving mechanism and consists of one continuous drive shaft on which are oppositely mounted two pairs of ordinary eccentrics, each pair operating one section of the screen. A uniformly rotating power-driven differential flywheel pulley imparts to the shaft a motion which is slow at first and then gradually accelerated toward the end of the forward stroke, then quickly reversed and retarded toward the end of the return stroke. This motion insures a continuous uniform travel of the coal at a suitable speed for screening and picking. A separate eccentric centrally mounted on the same drive shaft operates the reciprocating feeder and imparts to it the same irregular reciprocatory conveying motion which makes the feeder self-cleaning. Thus the cost, installation and maintenance of an independent feeder drive shaft with its bearings, supports and pulley is saved. This arrangement has the advantages afforded both by the apron type feeder and the old-style reciprocating feeder, while it possesses none of their inherent disadvantages.



A 25-hp. motor is employed for driving the screens which grade the coal and convey the refuse. The power actually consumed runs from 10 to 20 hp., varying with the load on the screens.

The feeder hopper is provided with a gate for by-passing run-of-mine coal directly to the railroad car without having to operate any of the shaker screen equipment. The coal may also be by-passed directly into the local-trade bin, which is arranged with gates and hinged chutes for loading wagons on the public road that passes under the tipple.

Picked run-of-mine may also be loaded by opening a gate near the discharge end of the upper screen and by-passing the material to the lower screen, where it may unite with the nut and slack and be loaded through a gate in the lip screen into a car on the slack track. By manipulating gates in the screen, any combination of sizes may readily be had on the three tracks.

Briefly summed up, the advantages of this type of equipment are: The balanced horizontal screen maintains its horizontal position at all periods in its cycle of operation, and conveys the coal over the screen at a speed such that picking facilities are afforded directly on the screen itself without the installation and maintenance of any separate picking tables and structure for them.

This is a balanced screen and requires no unusual supports or heavy concrete pier for foundation; the upper deck counteracts the reaction of the lower deck, both being driven from the same mechanism and from oppositely disposed eccentrics cast in one piece, so that,

VIEW OF BOTH DECKS OF THE SCREEN

theoretically, the reactions are neutralized within the castings without even passing to the shaft.

The reciprocating feeder is actuated from the screen-driving mechanism shaft and requires no separate drive shaft, bearings, transmission machinery or supports. In addition, this reciprocating feeder has the same peculiar conveying action as that of the screens, and is therefore self-cleaning.

All of the machinery and equipment is kept near the ground; thus the dumping point is lower. This means a lower structure and in shaft tipples a shorter hoist and an increased tonnage.

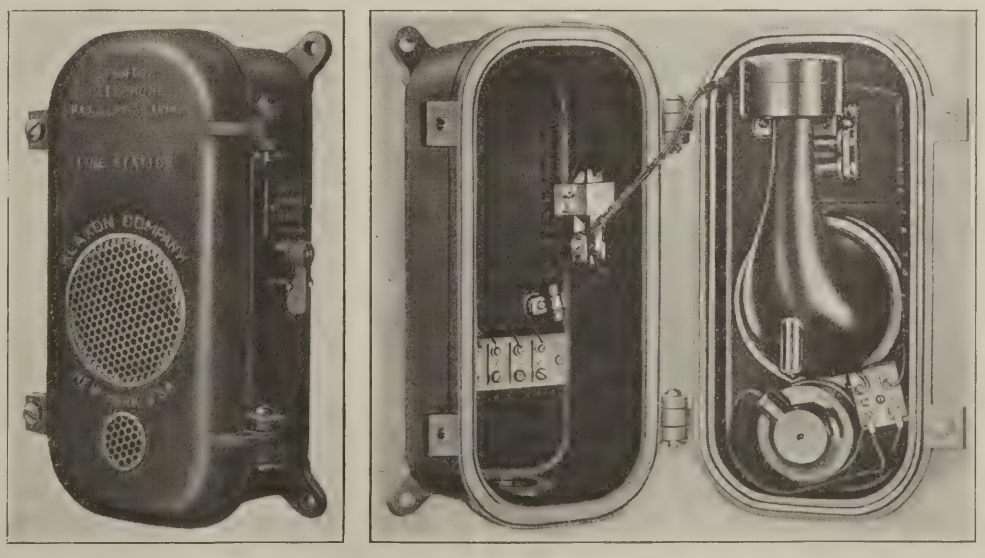
The tipple structure is simple and therefore costs less money than would be required for any other type of tipple equipment for the same purpose.

Provision is made for conveying refuse pickings either forward on a trough above the upper screen or backward on side troughs integral with the lower screen, which has a backward or reverse conveying action from that of the upper screen.

The reverse conveying of the lower screen permits wide flexibility in combining the various sizes; picked lump can be taken back for combination and loading with other sizes.

The cost of the machinery and equipment is comparatively low and the simplicity affords ready installation in existing or new structures.

The complete tipple equipment described in the foregoing was designed and installed by Jacobsen & Schraeder, Inc., engineers, Marquette Building, Chicago, Ill. The Van Kirk-Carroll Coal Co. is now installing similar equipment at its other mines.



New Telephone Admirably Adapted for Use in Mines

The Klaxon Co., of New York, will shortly place upon the mine market what it calls its Stentor telephone. This instrument has been developed primarily for use on battleships, where conditions of service are decidedly severe and the intercommunication system must be equal to any and all emergencies. Thus developed, the instrument is admirably adapted to use in mines.

The Stentor instrument differs radically in construction and results from the ordinary telephone even of mine type. As may be seen in the accompanying illustration, it is entirely devoid of both external receiver and transmitter. While these elements are of course present, they are attached to the inner surface of the box cover and might thus be rightly termed internal, in contradistinction to the external parts of the ordinary instrument. The distinguishing characteristic of this device, however, lies in the volume and distinctness of the sound transmitted. The diaphragm of this instrument is mounted between rubber cushions, or gaskets, with the result that the sound transmitted is extremely distinct and penetrating. Under favorable conditions a person may stand 5 to 20 ft. away from the instrument and yet hear and be heard with ease.

The construction of this instrument is heavy and rugged. The case is of a special brass or bronze composition, which is of course rust and corrosion resisting. The hinged cover bears upon a rubber gasket and is fastened to the instrument box by means of cap screws. The working parts are thus effectually sealed weather, water and gas tight. All exposed parts are either of bronze composition or are copper plated. So thorough is this protection from injury by the elements that the instrument may be entirely immersed without deterioration. What this may mean in case of a mine flood will be readily appreciated.

These instruments may be connected to each other or to a central station in the same manner as the ordinary telephone. Its small size, reliability, ease of operation (the lever at the side is merely pressed in order to call central or signal another station) and loud, distinct tone are factors that should be decidedly in its favor for mine installation.

VIEWS OF THE STENTOR TELEPHONE, SHOWING MECHANICAL DETAILS

Nitro-Starch as an Explosive

Nitro-starch, which in some of its properties is superior to nitro-cellulose (guncotton) and nitroglycerine, seemed at one time likely to establish itself as a useful explosive, but, as formerly manufactured, it was wanting in stability. Perhaps its constitution was not fully understood. War requirements directed attention to this compound, and a safe explosive was produced from tapioca-starch. Tapioca-starch has long been used in large quantities by the Post Office Department for the gum of postage stamps. The need for this substance in the form of an explosive led to a search for a substitute. This was soon discovered and after rapid but intense research it was found that nitro-starch possessing the required stability can be made from corn-starch, the product being better in quality and cheaper than that obtained from tapioca.—*Chemical and Metallurgical Engineering.*

Coal Age Index for Last Half of 1918 Ready in February

An index to *Coal Age* for the last half of 1918 will be ready for distribution some time in February, and will be sent free to anyone addressing a request to the subscription department of *Coal Age*, New York City.

Statistical Program of Fuel Administration May Be Abridged

Apparently the Secretary of the Interior is not convinced that the coal industry is entitled to a continuance of the broad statistical program being conducted by the Fuel Administration. If Secretary Lane so desires, this statistical work can be continued in his department until July 1 on money already appropriated to the Fuel Administration. If the program is continued after July 1, it will be necessary to secure an additional appropriation.

Congress, however, is inclined to view with favor the expenditure of money for statistics, because it supplies consumers and the smaller operators and dealers with most valuable trade information which they would not be able to collect for themselves. On the other hand, the more highly organized concerns have an advantage in the absence of Government statistics, from the fact that they are able to support statistical divisions of their own and are enabled thereby to have more insight into the general situation. This argument, as a rule, is effective with the appropriations committees.

The statistics, which are being gathered by the Fuel Administration, cover the details of production, distribution, consumption and stocks.

Improvement of Ohio and Mississippi Rivers Will Benefit Kentucky Coal Industry

That the improvement of the Ohio and the Mississippi Rivers is of importance to the Kentucky coal industry is indicated by the statements made by C. F. Richardson, the president of the West Kentucky Coal Co., in a letter to Representative Barkley. The letter reads:

You no doubt are familiar with the recent rivers and harbors bill, there not being any appropriation made for the improvement of the Ohio River other than the unexpended appropriations which have been tied up under contract for the Ohio River improvement.

The improvements on the Ohio River are of vital importance to all of the people who live on the Ohio and adjacent to it, and inasmuch as about one-sixth of the population of the whole United States live in the Ohio and Mississippi Valleys it seems to me that the benefits that these citizens can derive from having the Ohio and Mississippi Rivers made navigable continuously during the year are such that our representatives in Congress should not overlook the importance of making the necessary appropriations to complete the great work that has already been begun in order that the public may have the benefit of these great waterways.

The West Kentucky Coal Co. is especially interested in the improvement of the lower Ohio as well as the Mississippi River, but more especially in the lower Ohio. Under ordinary conditions we transport half a million tons of coal down the Ohio River from our mines located near Caseyville, Ky., and on account of the present river condition we are only permitted to operate approximately seven months in the year, and these operating months are contingent on the flood stages of the water. With the proper improvements we could have continuous operation and could transport one and a half million tons of coal with the same equipment that we now have, and I am sadly disappointed that no appropriation was made in this session of Congress to take care of the necessary improvements on the lower Ohio.

With the present high labor cost on railroads, as well as the congestion of the railroads at various periods of the year, it makes it more necessary that improved river transportation should receive the necessary attention. In periods of car shortage, as well as other transportation facilities, if the Ohio and Mississippi Rivers were put in the condition in which they can be put at a nominal cost, then the citizens living along these two great rivers could be served not only with coal but with various other commodities which have been most difficult for them to get transported to the towns and cities bordering these two rivers; and with these increased transportation facilities better car supply, as well as motive power, could be diverted to other localities where they would be needed.

I earnestly request that you use every effort in your power to see that something is done at the next session of Congress, and if possible at the present session, to have the necessary appropriations made for a continuance of the improvements of the lower Ohio River and not have it delayed for two or three generations to come. This country is in need of this improvement, and it should be given immediate attention; and if the necessary appropriations are made, it would help solve the great question of what are we going to do to find work for the returning soldiers.

Coal and Coke Fuel Administration Cancels Requisition Orders

All orders for the requisition of coal or coke, whether they are now outstanding or issued prior to the present time, have been cancelled and annulled, to take effect on Jan. 31, it was announced Jan. 23 by the United States Fuel Administration.

Permits Required for Certain Smokeless Coal Shipments

To correct a slight misconception of its order of Jan. 16, regarding the removal of restrictions on shipments of bituminous coal and smokeless coal by way of the docks on Lake Michigan and Lake Superior, the United States Fuel Administration pointed out on Jan.

21 that this order still keeps in effect a provision that: "Low-volatile smokeless coal shall not be sold or shipped from docks on Lake Michigan and Lake Superior for use by domestic consumers unless a permit for such sale or shipment shall first have been obtained from the District Representative of the United States Fuel Administration in charge of said docks."

The order also declared valid all permits heretofore or hereafter obtained from the District Representative in charge of said docks, under the proviso of the order of Jan. 2, 1919, although granted without the approval of the Federal Fuel Administrator.

Record Custodian for United States Fuel Administration

Harold B. Harris was appointed on Jan. 21 Custodian of Records of the United States Fuel Administration. Mr. Harris has been a member of the Bureau of State Organizations of the Fuel Administration and has had charge of retail prices. By the terms of the order, issued on Jan. 21, he has "authority to make such arrangements as shall be necessary and proper for the custody, safe-keeping and disposition of all records and documents of the United States Fuel Administration."

Question of Railroad Fuel Interesting the Coal Industry

Railroad fuel has furnished the matter of liveliest interest in Washington during the past week. The statement of policy with regard to the purchase of railroad fuel, made recently by the Director General of Railroads, is highly satisfactory to such representatives of the coal industry as are in Washington, but it is felt that the statement does not go far enough. If the employment situation is kept secure, it is realized that railroad fuel purchases must be made in such a manner as to make fairly equitable distribution of contracts within the various fields. If the tonnage is not spread out well between the different districts and within each district, irregularities in employment are certain to arise.

In such negotiations as have been had with Director General Hines, he has shown an unmistakable disposition to be fair and broadminded, his callers testify unanimously. They have hoped that he will make a definite trial of some systematic distribution of orders.

The plan of the Railroad Administration to ask for bids on coal is a departure from past methods which is being watched with interest. Some operators have suggested to the Railroad Administration that there be a fixed price established for Government coal. The industrial situation is such that it is practically certain that the Government, as a large purchaser of raw materials, will take that situation into account.

In order to protect themselves from an influx of high-grade coal, when the zones are abandoned, retailers in certain cities where there are stocks of low-grade fuel still on hand are entering into an agreement not to bring in any high-grade coal until the surplus of low-grade coal is disposed of.

Mining Institute To Hold Joint Meeting with Canadian and Electrical Institutes

The American Institute of Mining Engineers will meet on Feb. 17 to 20 with headquarters at the Engineering Societies Building, 29 West 39th St., New York City. Joint sessions will be held with the Canadian Mining Institute and the American Institute of Electrical Engineers. The program is as follows:

Monday, Feb. 17—Registration at Institute Headquarters, 9 a.m. to 9 p.m.; Simultaneous Sessions of "Institute of Metals Division" and "Industrial Organization," 10 a.m.; Luncheon at Headquarters, 12:30 p.m.; Simultaneous Sessions of "Institute of Metals Division" and "Industrial Organization," 2 a.m. to 5 p.m.; Visit to Morgan Galleries, 3 p.m.; Evening entertainment, 8:30 p.m.

Tuesday, Feb. 18, Canadian Mining Institute Day—Annual Business Meeting, 9:30 a.m.; Simultaneous Sessions on "Principles of Taxation" and on "Iron and Steel," 10 a.m.; Meeting of the Women's Auxiliary, 11 a.m.; Meeting of Boards of Directors, 12 m.; Luncheon at Headquarters, 12:30 p.m.; Discussion of International Coöperation in Mining in North America; Improved Relations of Capital and Labor; Uniform Mining Law for North America, 2:30 p.m. to 5 p.m.; Visit to Metropolitan Museum of Art and Senator Clark's galleries, 3 p.m.; Smoker, 8:30 p.m.

Wednesday, Feb. 19—Session of National Council, 10 a.m.; Session on Mining, Milling and Geology, 10 a.m.; Meeting of Women's Auxiliary, 11 a.m.; Luncheon at Headquarters, 12:30 p.m.; Matinee for Ladies, 2:30 p.m.; Joint Session with American Institute of Electrical Engineers on Electric Welding, 2:30 p.m. to 5 p.m.; President's Reception, 6:30 p.m.; Annual Banquet followed by Dancing, 7:30 p.m.

Thursday, Feb. 20—All-day trip to Newark Bay to visit Federal Shipyard, where the first electrically welded ship is being built. A ship launching will add to the interest.

The Coal and Coke Committee will present the following papers: "Anthracite Mine Costs," by R. V. Norris; "Work of National Production Committee, United States Fuel Administration," by J. B. Neale, and "Distribution of Coal under United States Fuel Administration," by J. D. A. Morrow.

The Industrial Organization Committee will conduct discussions on housing and Americanization. It lists the following addresses: "Prevention of Illness Among Employees in Mines," by A. V. Lanza; "Professional Section—United States Employment Service," by I. W. Litchfield. "Use of Cripples in Industry," by J. P. Monroe; "Need for Vocational Schools in Mining Communities," by J. C. Wright; "Employment of Mine Labor," by H. M. Wilson; "Psychology Tests," by R. M. Yerkes; "Mental Factors in Industrial Organization," by T. T. Read.

Giving Credit Where Credit Is Due

In some unaccountable manner the Wyoming Coal Co., in Wyoming District No. 2 (see *Coal Age*, Jan. 16, page 96) was credited with a coal production of 430,099 tons. The tonnage is correct, but the coal was produced by the Monarch Coal Mining Co. instead of the Wyoming Coal Company.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

It has been recently announced, to be exact the date was Jan. 22, that the general disbandment of the United States Fuel Administration would not affect the Bureau of Labor which works under the Administration. It will continue its labors till the end of the war. Under an agreement published July 23, 1918, all labor questions pertaining to the coal-mining industry were placed definitely under the jurisdiction of the Fuel Administrator, this arrangement having the sanction of the Secretary of Labor and of the United Mine Workers of America. The agreement included the provision that any dispute failing of settlement between the parties at interest must be submitted to the Fuel Administration for final disposition without stoppage of work.

All Must Get at Least Present Average Wage

In the anthracite region a strike has broken out at the Heidelberg No. 1 and No. 2 Collieries of the Lehigh Valley Coal Co., at Dupont. The men went on strike Jan. 18 and on Jan. 24 were reported as still out. About 500 men are involved. A meeting has been held at which representatives of both the men and the company were present. The controversy arises from a desire to fix a minimum day's wage to average $6.63 per day. The company will not agree to it, of course. Dupont has always been a center of trouble and contract breaking.

It is interesting to compare the wages of anthracite mine workers with those of skilled workers in the city who have far higher living costs than the mine workers and where especially rent and coal are much higher than in the mining regions. According to the figures of the Fuel Administration the contract miner receives $6.63 daily or $39.78 a week. That is what the Heidelberg miners would make the minimum wage. The following is a list of the wages received by other workers, by the day and by the week:

	Daily	Weekly
Consideration miner...	$5.50	$33.00
Contract laborer	$3.70- 5.16	$22.20- 30.96
Company miner	4.56- 4.80	27.36- 28.80
Inside laborer	4.08- 4.32	24.48- 25.92
Common laborer	3.36- 3.68	20.16- 22.08
Shaft engineer	4.88- 5.20	29.28- 31.20
Fireman	3.84- 4.24	22.24- 25.44
Blacksmith	4.56- 4.80	27.36- 28.80
Carpenter	4.56- 4.80	27.36- 28.80
Machinery repairer....	4.40- 4.56	26.40- 27.36

Thus Does Scranton "Put It Over" Chicago

The United States Department of Labor issues the following statistics for full-time wages in Chicago, May 15, 1918. These, understand, are union scales:

Bricklayers, cement finishers, elevator constructors, marble setters, painters, stone masons, tile layers, granite cutters and iron molders, $33 weekly; asbestos workers, carpenters, sheet metal workers, structural iron workers and finishers, each $31.20 weekly; slate and tile roofers, $31.90 weekly; all-around machinists, $31.20 weekly; metal polishers, $26.88 weekly; building laborers, cement laborers, elevator helpers, hod-carriers, $22 weekly; machinery helpers, $18.24 weekly.

When it is considered that living costs are considerably higher in metropolitan cities, the mine-workers living in communities of smaller populations have more leeway for the worth of a dollar, as its purchasing powers go further.

The coal miners of the Nesquehoning region are declaring defiantly that if the country goes dry they will not mine coal. They allege that stimulants are absolutely necessary if they are to do such heavy work, and they say that if they are deprived of the beer, on which their strength depends, they will seek employment less hazardous and more conducive to health. Where they will find an employment more conducive to health cannot be imagined. Lots of work, it is true, is less hazardous, but the work on which they are engaged will become decreasingly hazardous when their nerves and their judgments are not unsteadied by alcohol. The story that beer is necessary for the hard worker is one of the prize fables of the brewery storyteller.

In central Pennsylvania much friction has arisen at the Winber plants of the Berwind White Coal Mining Co. and as a result the Winber Citizens' Association has been formed, the merchants of the town forming the background of the body created to attack the policies of the company. The Winber citizens, who are all either employees of the corporation or derive their whole trade and living from those who are the company's employees, allege that their meetings are watched, and the employees of the corporation who attend the meetings are "fired" the next day.

The mine workers complain that the company has been quite active in municipal politics and has been discharging all men whom they believe have voted against such officials of the company as were seeking municipal preferment. They claim not only that the company discharges those actively opposing it but also blacklists them when they seek employment elsewhere. An appeal has been made to the United States Secretary of Labor for an investigation of the conditions alleged by the mine workers.

Illinois Miners Want More Compensation

Illinois miners think that workmen's compensation legislation should be changed from time to time in keeping with fluctuations in wages and increases in the cost of living. Local No. 304, United Mine Workers, of Belleville, Ill., has adopted a resolution asking the Illinois legislature, now in session, to increase the rate of compensation to injured persons. They say that the rates now in effect are based on wages and the cost of living prior to 1916 and therefore do not meet the exigencies of the present situation. The same resolution is to be adopted by miners' locals all over the State and forwarded to Springfield to be presented to the legislature.

Walter Nesbit of Belleville, secretary-treasurer of the Illinois mine workers, has made an appeal to the legislature for the relief of the suffering existing among the miners of the state as a result of the influenza epidemic. He states that 740 miners died from influenza or pneumonia, leaving dependent families and parents, and that a majority of these families have been left without support.

Operators Want Present Wage Scale Upheld Till Cost of Living Drops

The Winding Gulf Operators' Association at its last meeting passed resolutions favoring the establishment of a miners' state hospital in the Winding Gulf region, calling for certain changes in the compensation law (*Coal Age*, Vol. XV, p. 152), advocating an increase in the salaries of the chief of the Department of Mines and the district inspectors, and urging a continuance of the present scale of wages:

"Resolved, That it is the sense of this meeting of the Winding Gulf Operators' Association that our field has reached a state of development and attained a population which makes it very desirable and necessary that a state hospital be established, and that this hospital should be so located as to be convenient to the greater number of operations in the field, and that a committee be appointed by the chairman to see that this matter is properly presented to the Legislature at this session by our local representatives.

"Resolved, That there are some changes necessary in the present Compensation Law in order to enable the Commissioner of Compensation to make a more liberal distribution of the funds at his disposal; that this association is in favor of these changes being made; and, it is the sense of this meeting that any changes contemplated in the present Compensation Law should include a provision requiring the State Compensation Commissioner to make a complete detailed quarterly financial report to be published in the newspapers throughout the state.

"Resolved, That the chief of the Department of Mines and the district mine inspectors fill positions which carry responsibilities for which they should be more adequately compensated. That we are in favor of the chief of the Department of Mines receiving a salary of $5000 per annum, plus expenses, and the district mine inspectors receiving salaries of $3600 per annum, plus expenses, and that the appropriations for paying these salaries be made as heretofore has been done.

"Resolved, That in view of the continued high cost of living the Winding Gulf Operators' Association is in favor of the present scale of wages and desires to maintain same as long as market conditions permit."

New Wage Scale in West Virginia

The operators and mine workers of West Virginia will meet in the next few weeks to open their conferences relative to the wage scale for the year beginning Apr. 1, for at that time the present scale agreement expires. The conference will find many miners in West Virginia, not out of work exactly but not suffered to work regularly because of the curtailed demand. However, if a resolution of the Winding Gulf Operators' Association may be accepted as showing the attitude of operators, they will not seize upon the shortage of orders as a reason for forcing down wages. Until an agreement is reached as to next year's scale of wages, labor conditions will be more or less unsettled.

It seems as if the West Virginia operators were proposing to do their duty by operators in other states, for they are not seeking a wage reduction though it would be somewhat profitable as they, if successful, would secure it first. It would be unfortunate if the West Virginia district were to attempt to attain such a temporary advantage. Reductions in wages would be peculiarly regrettable at this time, for all such revisions downward would suggest other changes in the same direction but in greater measure. As a result business would begin to doubt whether it was resting on rock bottom or on a snow ledge over a fathomless abyss.

A scale convention for the Winding Gulf field met at Beckley on Jan. 23 for the purpose of formulating the miners' demands for the new scale year.

While mines are being operated irregularly, there does not appear to be much shifting about from plant to plant, even though some companies are more in need of men than others. This is regarded as a healthy sign.

Let Who Will Make Laws for the Operator Mine Workers Will Make Their Own

For several months the coal miners of the Crowsnest field have been working single-shift. This concession was granted during the strike of last September. All the parties concerned arrived at an understanding under which a Royal Commission was to be appointed immediately, which commission was to make inquiry into charges that the mines of the district were unsafe to life while operated on the basis of two shifts in 24 hours.

It now appears that the men, satisfied with present conditions, do not propose appointing a representative to the commission, a course which, it was understood, they were to take, the personnel to be completed by appointees of the Crow's Nest Pass Coal Co. and of the Minister of Mines. What course will be adopted as a result of this announcement is difficult to say, but it seems certain that the company will not be content to allow the situation to remain unchanged, for the officials of the corporation feel that the working of two shifts does not reduce the safety of the workings and that the continuance of the single shaft materially lowers the output and lessens the returns to be derived from the operation of the property.

The following resolution was adopted at a recent meeting of the Gladstone local union of Fernie, B. C.:

"Order 26 decreed that the miners at Coal Creek and Michel resume work on single-shift for an indefinite period pending the report of a Royal Commission. As we have been actuated in taking our position solely from our desire for the greater safety of the mines, we have viewed with great concern the probabilities that such a commission, composed as it will be of men of lesser efficiency or repute in the mining world, would take ill-advised action.

"We, the members of the Gladstone local union, protest that we did not seek or request, either individually or collectively, that the expert judgment of G. S. Rice, of the United States Bureau of Mines, be sought in this matter, though we recognize that he is the authority of highest repute on the American continent. The evidence on which he based his report was furnished exclusively by the Crow's Nest Pass Coal Co. and the Department of Mines. We complain that we were not informed of the conditions at the No. 3 mine which led to the disastrous explosion at that colliery. Yet the Department of Mines had already on file G. S. Rice's report regarding those conditions, which report clearly shows that the flash point should be reduced from 5.5 to 2.5 in those mines.

"Since the above-mentioned disaster men have been withdrawn from their places in the mine when the cap on the lamp is ¾ in. high or higher, whereas before that time withdrawal was required only when a ½ in. or higher cap was exhibited. This shows that the Department of Mines must have some faith in the Rice report on which we based our argument.

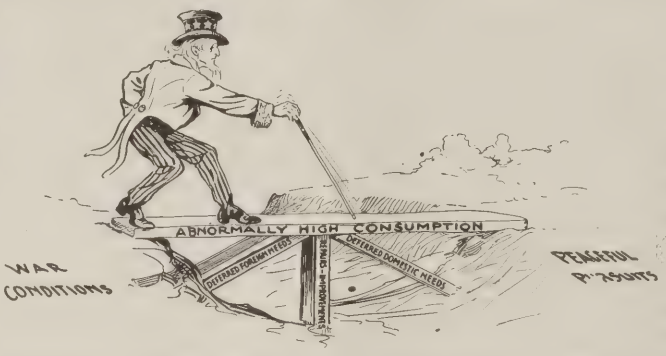
"All commissions that have been appointed to settle disputes between capital and labor have invariably been unsatisfactory to labor. For these several reasons we, the members of Gladstone Local Union, No. 2314, United Mine Workers of America, absolutely refuse to take any part whatever in the aforementioned commission."

Ohio Miners Couple Steady Work with Government Ownership

That part of the United Mine Workers centered in Ohio, at the annual convention held in Columbus recently, adopted resolutions favoring Government ownership and the steady operation of all coal mines. The delegates voiced the opinion that only under Government ownership could the miners get full justice as to wage and working conditions. A resolution was also adopted asking for legislation increasing the maximum weekly compensation for injury and disability. The convention urged that pay be made weekly.

The housing and the sanitary conditions of the various coal-mining villages was given as the cause of the high percentage of fatalities occurring during the recent influenza epidemic. The Ohio legislature was asked to remedy that condition by the enactment of more stringent sanitary regulations.

It was forecast that a special "international" meeting of miners would be called immediately after the signing of peace, when the entire question of a new wage scale will be discussed. Under the agreement with the Federal Government the present scale is to continue during the war. It is believed that higher wages and better working conditions will be demanded.



The working mine employees in the Yorkshire mines, England, numbering some 150,000 men, on Jan. 22, decided to quit work in order to enforce an extra 20-min. lunch time, 40,000 men having already been locked out for attempting to put the new lunch hour into effective operation. Sir Guy Calthorp, the Coal Controller, conceded the "snap" demanded and work continued. The mine workers were even threatening to bring out all enginemen, firemen and boilermen. A desire to reduce output and compel the employment of both returned soldiers and the persons who replaced them during the war was probably the cause for the demand.

EDITORIALS

The Dangers Are All in Our Fears

FOR THE nonce Uncle Sam is like a man who steps out on a plank bridge and wonders if it is likely to break, and how far it would be if he fell. There won't be much work done for a while if he continues to suspect the strong plank under him, though it is a safe wager that it would hold up a dozen such men as he.

There are big prospects ahead here and some abroad. To begin with, the United States furnishes enough work for all its citizens whenever those citizens go briskly about their business relying on the prosperity of the country. When they go feeling around in doubt and fear, there is not enough work here or in any country. Whenever there are silly people busily assuring their neighbors that profits and wages must both be largely curtailed, of course no one will buy. These men are the enemies of the country, perhaps greater enemies than the pacifists and pro-Germans. They create the idleness that breaks the cohesion and morale of the nation. They proclaim when they preach lower prices or lower wages that there must be a revolution against the employing class or the working class, or both.

If it were true that a great modification in prices is at hand, it would be hard for any of us to refrain from prophesying it; and if it has to come, we might wish it to come early. But it does not have to come. If we don't sit up, wait for it and fuss over it, it won't come. There is nothing particularly disconcerting about the present high wages, if indeed we can call them high wages, for in most cases they do not represent an excess of purchasing power.

Since the Middle Ages (when an English two-cent penny a day was a good day's hire in England) to the present day (when 250 of those same pennies is considered hardly enough to keep an average family in health) there has been a steady rise in the actual and nominal wage of employees. The actual wage has risen partly because machinery, efficiency and steady employment have increased production and partly because the decline of flunkeyism and the cessation of certain kinds of waste have prevented the drain on capital which reduced the quantity of available production.

The nominal wage has increased even more, and that specious change in the rate of pay has come from industrial exigencies and from the importunity of labor unions. Some unions have been actuated by the vain and foolish hope that wage increases could be conceded without causing an equivalent rise in the cost of living. Others, better weighing economic causes and effects, have been animated by the immoral expectation that by getting wage rises first the other wage earners who did not get an increase in wage would be obliged to pay tribute to those who did.

But the point to be made clear is that in, say, 500 or 600 years wages have multiplied, in part nominally and in part actually, 250 times, mostly during wars. What reason is there to believe that a doubling of wage during the present struggle is a tide which must have a regression. History shows that the wage increase during a war is inevitable, and that the readjustment after the war does not bring the scale back to its original level. History also records that the high wage does nobody any harm except the gold-mine corporations, the holders of bonds, the hoarders of money, insured and pensioned persons. With all due respect to these people, we wish to see everything move along regardless of them and their wishes. None of them would gain by such a restriction of business as would readjust the face values of wages and profits to their former level. Such a setting back in wage would involve a cataclysm of such magnitude that it would render their securities of little value.

The world can go on working with the higher wages as well as it did with the lower wages. If wages were again doubled, no great harm would be done to most of us, and there would be no appreciable benefit to any one but the borrowers of money and the payers of pensions and industrial compensation. Unfortunately, everybody assumes that the condition of high wages is so irretrievably bad that it must be corrected sooner or later—and why wait till later? The situation is not bad at all, only our reaction to it. Let us see the matter in the right way and there will be an end to the seriousness of the problem.

Conditions are favorable to more than normal prosperity. Before the war people were being fast educated to desire more commodities than ever before. Automobiles, plumbing fixtures, good homes, artistic house furnishings, traveling facilities—all were in unusually large demand before we entered the conflict.

Patriotic people, despite the growth of the desire for the good things of life, suddenly cut off the purchasing of all articles for which there was no great necessity. For some months, if not for some years, they endured hard conditions so that the war might be won. Their tastes have not been changed; their ambitions are not reduced; they are ready to buy again in large volume. Now that the war is over they are free to express their desires in purchases. Business is sure to be brisk, and being brisk, it will be profitable.

As for export business it must be good—for a while at least. Europe wants so much of what we can supply. For a few years Europe will be willing to borrow and we to lend, and so long as that condition lasts exports will be fair. Of that there is no doubt. Even if there is not much coal in what is sent to Europe, what matter? A man at Kokomo, Ind., is just as desirable a customer as one at St. Etienne, France. Why worry? This country is big, and its demands are large. Whether only a ton, ten million or one hundred million tons of coal a year go to Europe is no matter so long as our market here is good. And good it will be as soon as Uncle Sam quits looking at his plank, throws his head up and jauntily swings across the gully.

Great Britain says: "I can produce more than my people can consume. I must export my surplus." France puts the same into Parisian, with a shrug, and the Italian repeats the sentiment in his language with an appropriate gesture. We are all saying the same thing. We are all going to export a surplus. That surplus is the yellow dog that all must shoo from the door. There is no place for him unless it be an international dog pound, and the pound has not yet been established. For the most part we, in the United States, must look to our own people to take our staples. There is a good steady market abroad for our mechanical devices and our machinery, but some staples which have been home stayers in the past may have to be truly patriotic and stay in the U. S. A., and be at home to welcome other staples that Europe will send to pay for our manufactured articles, our copper and our loans. But there is an endless demand if the old gentleman will quit feeling about so tremulously with his cane. The bridge is strong. Reconstruction is not needed. All we need is resumption and, as we learned years ago, the way to resumption is to resume.

Opportunity for Export of American Coal

ENGLAND is short of coal. Her needs, so far as fuel is concerned, are as great now as at any period during the war. No reserve stocks of coal have been accumulated, and until these reserves have been built up for transport, domestic, industrial and public utility purposes, Britain must resort to rationing.

In the South Wales district coal production has decreased to an abnormal extent. Furthermore, the South Wales Miners Federation is making a determined effort to secure a six-hour work day. If the miners succeed in carrying the measure through, the annual coal output of the United Kingdom will as a result decline several millions of tons.

Italy is so urgently in need of coal that she is seeking to control its purchase and distribution so that fuel may be more plentiful and more equitably apportioned. For this reason, the Italian government desires a complete monopoly in the sale of coal within her own borders. France and Belgium, unable to procure enough coal from their ally, Great Britain, are looking to Germany for their necessary supply, and expect to set off its purchase price against the indemnities and compensations demanded of the German people.

All this is of particular significance to the American producer of bituminous coal. The soft-coal mines, owing to pressure of war demands during the war period, demonstrated their ability to produce millions of tons of coal above normal requirements. Having expanded their capacity to such an unprecedented extent, these mines must now either curtail production or find an outlet for the surplus tonnage. The former plan is a most unsatisfactory solution of the problem; the latter plan can be adopted if certain changes are brought about in American shipping conditions.

Right now is the psychological moment for the building up of a large South American export trade in United States coal. England, for some time to come, will be unable to take care of her European fuel obligations let alone look after her South American business. Given enough cheap bottoms to compete with vessels from South Wales and Australia, which have been supplying the bulk of South America's coal needs, there is no reason why the United States could not capture the Latin American markets.

To further the interests of coal operators who are desirous of entering foreign markets, *Coal Age* with this issue has inaugurated a new department to be headed "Foreign Markets and Export News." Under this head will appear items and information having a direct bearing on the subject of coal export, such as foreign market conditions, ocean shipping rates, opportunities in outside markets, coal-export statistics and so on. *Coal Age* would like to see this department grow and become of real value to the industry. To this end the coöperation of its readers is solicited. Correspondence is invited on the subject of coal exports, which promises to become one of ever-increasing importance to American coal producers.

Hunt a Culprit to Excuse Themselves

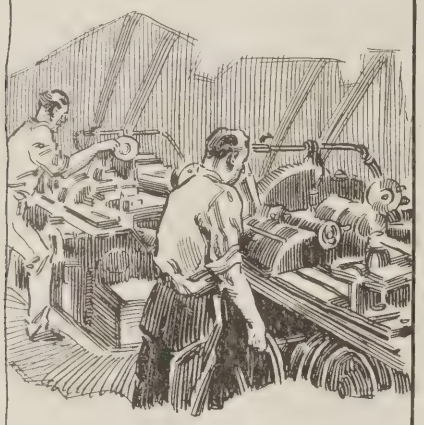
THE mine workers in Ohio are trying to blame the coal operators for the disastrous plague of influenza. An epidemic occurs and carries off a million or so of people, and the Ohio mine workers try to put the burden of the offense, as far as it concerns themselves, on insanitary housing and unhygienic conditions.

Most of the towns in the mining districts of Ohio are old. The greater part of them doubtless reflect the ideas of the close of the century just passed. They are probably none too sanitary. A commission of examination might conceivably do no harm. Typhoid and malaria are only too common in many mining towns, and it is quite likely that the Ohio coal towns have their share of the first, at least.

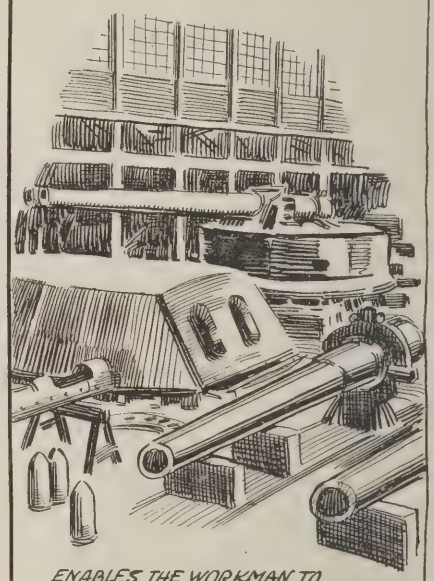
But influenza is spread solely by disregard of certain conventions, and so far as we know not at all by lack of sanitation, using that word in a broad community sense. The disease of influenza can best be kept from spreading by personal isolation. Every person should have his own washing and eating utensils. In fact the precautions that should be taken are almost innumerable. A careful man, who has learned to dread contact with other persons, will take them instinctively. A careless man will oppose them all—and will blame the landlord for the results.

It is said that a campaign for sanitation is proposed by the unions. Well and good, but let them remember that as Jerusalem was kept clean by every man sweeping his own doorstep, so will the mining towns be sanitary if every householder tries to abate his own nuisances.

Peace How The Miner Is The Good Friend Of His Fellow Workman Both In Peace And In War

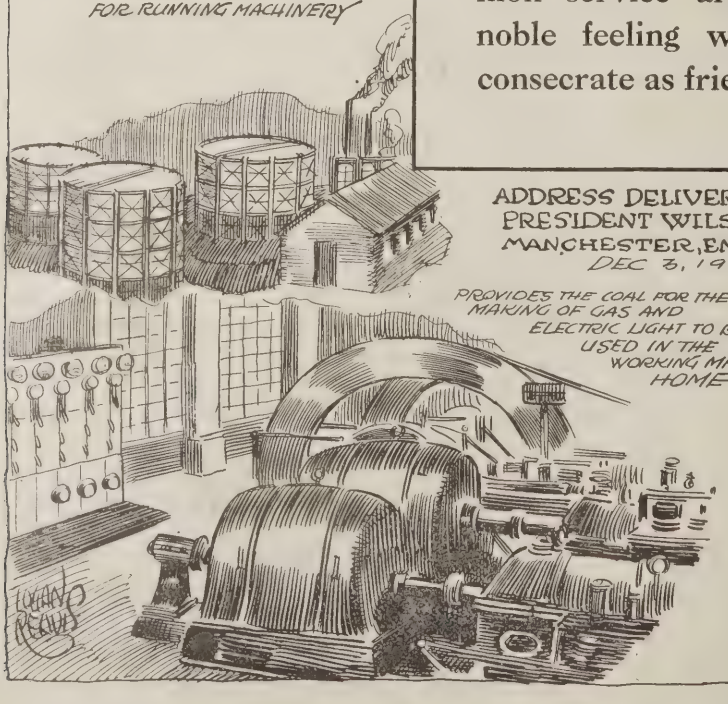


FURNISHES THE WORKMAN WITH FUEL FOR HIS STOVE

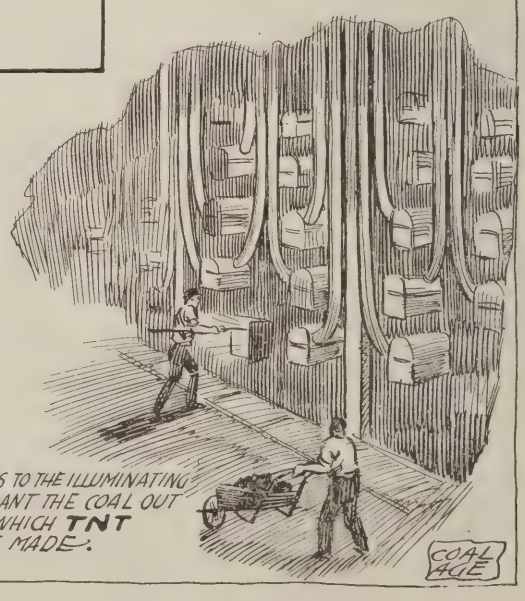


FUELS THE TRANSPORTS TO CARRY THE BOYS ACROSS THE SEA

FRIENDSHIP is not a mere sentiment. Patriotism is not a mere sentiment. It is based upon a principle, upon the principle that leads a man to give more than he demands. Similarly, friendship is based not merely upon affection, but upon common service. The man is not your friend who is not willing to serve you and you are not his friend unless you are willing to serve him. And out of that impulse of common interest and desire of common service arises that noble feeling which we consecrate as friendship.



SUPPLIES POWER FOR RUNNING MACHINERY



ENABLES THE WORKMAN TO MAKE SHELLS, TANKS AND GUNS FOR HIS DEFENSE.

ADDRESS DELIVERED BY PRESIDENT WILSON AT MANCHESTER, ENGLAND DEC 3, 1918

PROVIDES THE COAL FOR THE MAKING OF GAS AND ELECTRIC LIGHT TO BE USED IN THE WORKING MAN'S HOME

DELIVERS TO THE ILLUMINATING GAS PLANT THE COAL OUT OF WHICH TNT IS MADE.

COAL AGE

DISCUSSION BY READERS

Traffic with Germany

Letter No. 1—The editorial that appeared in *Coal Age*, Nov. 14, p. 910, entitled "Shall We Traffic with Germany?" was read with much thought and deep interest. The article draws attention to the fact that, in order to enable Germany to pay her great debt that she has incurred in the prosecution of the war, we must both accept of her labor and buy the products of that labor. This is the only sane way of looking the situation in the face. It is the only means open to the Germany of the future for liquidating her debt.

I am but expressing the views of the average American in stating that we longed to see the Huns driven back to Berlin, and to have had the conquering hosts of the allies occupy that country and set up a provisional government therein, until such time as they were satisfied that the German people were fit to govern themselves.

The Situation Regarding Germany, Defeated But Not Conquered

It must be admitted, however, that Germany is defeated but not conquered. In view of the atrocities she has committed and the laws she has violated, Germany is in no condition to be treated with, at present. There is, as yet, no government in that territory capable of negotiating peace. History for 200 years back furnishes no precedent to guide the peace commissioners in the work set before them. The task is stupendous. It should be done at once and done right, if there is to be formed a "League of Nations" that will insure a lasting peace.

But, to return to the question, "Shall we traffic with Germany?" Why not? Let me suggest that the position of Germany, today, is very much like the man whose wife has overdrawn his pay at the company store. The foreman of the mine knows that he must keep the man at work and make it possible for him to earn good wages so that he will be able to square himself at the store.

The Delinquent in the Mine, an Analogy

The situation presents one of the greatest impositions on a mine foreman who wants to deal fairly and justly with all his men. It is one that does violence to a foreman's ideas of justice and equity. While it is well for a management to assist its worthy men all they can, and there are always a number of these at every mine, it is an injustice to the other workers to keep one man in a good place where he can earn big money, and compel others to work in poorer places, because this one or that one is behind in his account with the company. A continuance of such a policy is sure to dissatisfy many good men who are thrifty and pay their accounts promptly. It is, indeed, far from dealing fairly and justly by men who want to do right.

The case I have cited presents a strong analogy to the position of Germany, following the war. She is in debt, with no available assets with which to pay. To boycott German goods and labor would take from her the only means that she has to free herself from indebtedness. At the same time, trade with Germany should not be allowed to impair our traffic with other countries. Goods and prices should be such as to insure equal justice to all.

American Ideals and Standards

Considered from an ethical standpoint, American standards and ideals would be lowered by adopting a policy that would not enable the German people to retrieve themselves and establish a higher and better form of government than the autocracy that has ruled them in the past. Let us not lower the estimate that our boys "over there" have created by the unselfish service they have given in the cause of democracy.

The attitude of Germany when our aircraft began to do damage over their border was that of a cringing cur. Forgetting the devastation created by her armies and airplanes, in Belgium, France and England, she at once set up a howl and threw up her hands when the war threatened her own country. The allies realized, however, that Germany, in her present condition, is a greater asset than a country devastated by war.

It was this consideration that led to the willingness of the allies to negotiate a peace and desist from the subjugation of the enemy. But, it will be necessary to establish a solid and stable government in that country, even if the boys have to march into Berlin to accomplish their purpose.

S. D. HAINLEY.

Fighting Publicity with Publicity

Letter No. 1—Not long ago, there appeared in *Coal Age* a very timely editorial entitled "Fighting Publicity with Publicity" [Nov. 21, p. 953]. Attention was then drawn to the exaggerated accounts, wrong statements and misrepresentations that are often made in the public press, by men and women who denounce the coal industry boldly, over their own signatures, which leads the public to believe in the truth of what is said. The suggestion was made that it would be far better if men, in the industry, would announce themselves with the same boldness and not permit the public to be misled by their silence.

The following incident will serve to show the reason why many men, holding inferior positions in large companies, but who are eminently able to treat subjects of interest connected with their calling, hesitate to have their names appear in print. The reason for this is to be found in the attitude of the management, in most large concerns. It is owing to this that many valuable discussions in *Coal Age* are signed only by some ficti-

tious or pen-name. An instance of this came to my notice recently.

Some years ago, a particular friend of mine frequently wrote articles that were published in *Coal Age* over his own name. A little later, he received a gentle hint that the company would rather not have its employees discuss matters pertaining to the industry, for publication. That this attitude is quite general among the larger coal companies is obvious, from the fact that the names of the employees of those companies seldom appear attached to the articles they write. However, it must be equally obvious to an intelligent management that much good has resulted to the coal industry through the publication of many of these nom-de-plume letters. How much greater good would have resulted had the same letters appeared over the names of their writers?

Practical Advantage Gained in Publicity

The chief and, perhaps, the only objection a management would have to its men voicing their opinions publicly is that matters would occasionally appear that were not intended for publication. The danger of this is slight, however, where the policy of a company is well understood by its men who know, moreover, that such a procedure would endanger their position in the company. Since the episode just cited occurred, my friend's name has not appeared in print.

A practical application of the principle of *fighting publicity with publicity* is illustrated in the growing discontent of large classes of miners, growing out of the statements being continually made by agitators that the men are not receiving a fair wage, in proportion to the selling price of the coal they mine.

Were these statements permitted to go unchallenged, they would soon be accepted as true; whereas, superintendents and foremen, did they feel free to do so, would soon show the falsity of such a claim. It is these men whose familiarity with the situation would make their statements accepted and prevent the injustice otherwise done to the industry. JUSTICE.

Birmingham, Ala.

Perils in Reconstruction

Letter No. 1—I was deeply interested in reading the Foreword that appeared in *Coal Age*, Nov. 14, entitled "The War is Won, Now Let Us Win the Peace." The article furnishes the sober-minded person with plenty of food for reflection. It emphasizes the fact that one's patriotism and duties as a citizen, which have been so stimulated during the period of the war, must not cease now that peace is in sight.

As stated in the Foreword, "Peace has its problems not less acute than war." The coal-mining industry of this country is going to play a large part in the reconstruction of Europe, and the scenes that are now transpiring on the Continent suggest that the coming period of reconstruction will be fraught with all the perils of the French Revolution.

From present reports, it appears that Germany and Austria are passing through the same experiences that have torn Russia apart. Bolshevism is on a rampage that threatens to menace the civilization of all Europe, unless the Allies secure and maintain a firm hold on the irresponsible elements now asserting themselves.

In order to realize the objects for which we have fought and establish a democracy that is safe to live in, it will be necessary to arrest the acts of murder, pillage and destruction that are now rife in those countries; and, with infinite patience, bring about a readjustment of affairs that will permit some stable form of self-government.

The industrial life of this country must play an unselfish part in the task of redeeming civilization. The condition of Russia today proves that Bolshevism is a failure. For over a year, now, affairs in that devoted country have furnished another hideous example of what anarchy will do for a nation, and have recalled the scenes of the French Revolution, from which, at great cost, has arisen a noble republic. Bolshevism is synonymous to the lowest type of socialism.

The effect of this peril in our own country, in time to come, remains to be seen. One is loath to believe that this counterpart of socialism will ever find a fertile soil for its growth in America, notwithstanding the clamoring for so-called "justice and equity" that is heard from time to time. The freedom of the press, which is the pride of the American people, affords the socialist element the desired opportunity to give expression to their opinion that there is nothing reprehensible in the wholesale murder and depredations now being committed, in Russia, in the name of the Bolsheviki.

Make Every Foreigner an American Citizen

There are foreigners working in the mines, in this country, who may sympathize with their countrymen in what they believe to be a struggle against oppression. The foreigner's training has led him to regard as oppressors everybody except the working man himself, but many of those of average intelligence, who are naturalized citizens of the United States, have become enlightened, and no longer harbor these thoughts of oppression. Such have affiliated themselves with their new surroundings and are striving to build up an enduring democracy that regards all men as equal.

The foreigner who has thus assimilated himself and become an American citizen is not impressed with the sayings of socialism and the doctrines of the I. W. W. To him, these both mean anarchy and the ultimate destruction of all the principles of equitable government. In order to avoid the perils that confront us, it is our duty to encourage literacy and the naturalization of the foreigner, so that he will cultivate American ideals.

Thomas, W. Va. PATRIOT.

Expediting Locomotive Haulage

Letter No. 1—Recent letters of writers in *Coal Age* have mentioned the difficulty experienced by mine operators in getting motor-runners who will take the necessary care of the expensive machines they operate. Complaint has been made of much time lost at the motor-repair pits, and the frequency of replacing burned out armatures due to "plugging" the motor. Mention has been made of the cost of repairing strained storage batteries and other high maintenance costs occasioned by the careless way in which the average motorman handles his machine.

It occurred to me that it might be of interest to readers of *Coal Age* to hear of a plan that we have

tried, on a small scale, at one of our mines, where we instituted a system of paying the motormen and the snappers a per-diem wage, lower than the usual wage, for a certain minimum tonnage of coal hauled daily. In addition, these men were paid a bonus for the tonnage hauled in excess of this amount, which gave all a chance to make more than was possible on the former per-diem basis.

What was the result? Where the locomotive crews formerly made from $5 to $6 a day, under the new system they have averaged from $7 to $8 a day. In the same 8-hr. shift, however, they hauled 30 per cent. more coal, owing to the increased interest taken to make good money.

The men were not slow to learn that all time lost at the motor-repair pit meant a direct loss to them in the bonus earned. On this account, they were anxious to learn the best methods of taking care of their locomotives, in order to reduce the time required to keep the machine in repair. They realized that all such work was unproductive labor on their part. There was, noticeably, a rapid increase in the number of burned out armatures, sulphated batteries, which showed a decreased cost of production per ton of coal hauled.

A remarkable fact, in this same connection, was that the old complaint of loaders and miners that they could not get cars to load was unheard, now, as the crews kept every miner well supplied with cars. Each motorman saw to it that his snapper lost no time in throwing switches and that he used extra care in coupling and uncoupling cars, which has been frequently the cause of much delay and accident.

Enterprising Motorman Gains Advantage by Monopolizing the Roller-Bearing Cars

About a week after the new system was started, an interesting outcome developed. At that time, about one-half of the cars in the mine were equipped with plain bearings and the other half with roller bearings. It soon appeared that one enterprising motorman, knowing how much easier it was to haul cars with roller bearings, had stolen a march on his fellows and had adroitly cornered most of the roller-bearing cars in his section of the mine. This enabled him to handle a greater number of cars in a trip and resulted in a good increase in his bonus for the time. There was also less delay in loading those cars, in that section, because of the ease with which the roller-bearing cars are handled in the rooms.

It did not take long, however, for the other crews to size up the situation; and it became necessary to instruct the men on the tipple to distribute the roller-bearing cars equally among the crews. As quickly as possible, all the cars used in the mine were changed to roller bearings and the situation greatly improved.

The principle underlying this system is not new. It is based on the fact that men will take better care of their own property, or what is producing revenue to them, than they will of the property of their company. Also, repairs to machinery formerly meant, to them, time for loafing; but under the new system, it meant a lower paycheck.

It is my belief that a similar bonus system could be used to advantage, in paying motormen in many mines, while, no doubt, in some mines, a straight tonnage-payment basis would be better. In either case, there would be an inducement for each motorman to haul the largest possible tonnage in a day.

Washington, D. C. Maverette Ashley.

Centrifugal Mine Pumps

Letter No. 2—Speaking of centrifugal pumps, permit me to give my experience with the same. About 15 months ago we changed our mine pumps, replacing seven steam pumps with four centrifugal pumps driven by electricity. Of the discarded steam pumps, three had a capacity of 2000 gal. per min.; two, 600 gal. per min.; and the remaining two, each, 1000 gal. per min.

Each of the centrifugal pumps installed has an estimated capacity of 2200 gal. per min. On a recent test, these pumps handled 2240 gal. per min., at a speed of 1760 r.p.m. The pumps consumed a current of 28.5 amp., at 2200 volts. Three of the centrifugals have handled the water at all times, thus far, without trouble; although, last spring, the flow of water in the mine was as great as at any time in six years.

Discharge and Suction Pipes Larger Than Their Respective Openings in Casing

Referring to the statements of William H. Grady, in his letter, *Coal Age*, Jan. 9, p. 66, regarding the relative size of discharge and suction pipes in centrifugal pumps, and their respective openings in the pump casing, let me say that I regard it as an advantage to have the discharge and suction lines of a pump larger than their respective openings in the pump casing. At least, that is my experience.

Our centrifugal pumps have 8-in. openings in the casing, and these are connected with 14-in. discharge and suction lines. Both the discharge and suction pipes are lined with wood. There is a foot valve at the bottom of the column pipe, while the suction pipe has no valve, but is equipped with a water-jet primer.

Since the installation of the centrifugal pumps we have had no trouble at all, and practically no expense for maintenance or repairs. We are also operating a small centrifugal pump to drain a large swag or dip in the entry. This pump has a 3-in. opening connected with a 5-in. wood lined pipe, at both the suction and discharge ends. A foot valve is provided on the suction of this pump and a gate valve on the discharge line. The pump has given the most excellent results since its installation 18 months ago. David Fulton.

Greensburg, Penn.

Efficiency in Firebossing

Letter No. 4—Referring to the question of securing the greatest efficiency in the work of firebossing, brought out in the excellent letter of F. G. J., *Coal Age*, Dec. 19, p. 1133, permit me to say that it is my belief that the fireboss should be employed and controlled by the state, in order to attain the highest efficiency in respect to his work.

When one reflects that the fireboss must often work under an inefficient foreman, obey his orders and frequently do things that he knows do not comply with the requirements of the state law and, perhaps, will jeopardize the lives of those working in the mine, it is clear

that he is placed in an awkward position. His refusal to obey the orders of his foreman would result, sooner or later, in his discharge.

Under these conditions, a man with a large family must think twice before undertaking the responsibilities of this position. I know of firebosses who would do anything they are told, without regard to whether their acts are lawful or dangerous to the men working in the mine. While some fear the consequences of refusing to comply with an order they consider unsafe or unlawful, others are controlled by a desire to stand in with the boss. Neither of these give a thought in regard to their individual responsibility to the state. They are unprincipled and a disgrace to their more conscientious fellows who are guided by their own judgment. The average fireboss, in my opinion, is a man that can be trusted, in every respect, by his fellow workers whose lives are in his charge daily.

It has often occurred to me that if the firebosses and mine foremen, in this state, would come together at regular meetings and discuss ways and means of overcoming the difficulties of their work, they would not only better their capabilities but assist the management by which they are employed. In this way, also, they would come to be recognized by their companies and by the general public, as the men who are chiefly responsible for the safety and welfare of all employed in the mines.

It is true that the superintendents, mine foremen and firebosses of the larger coal companies hold monthly meetings in their several camps; but I can safely say that the majority of firebosses go to those meetings with the firm conviction that the only safe policy for them to pursue is to say nothing in regard to the one feature of their work that is most discouraging and 0armful; namely, the lack of freedom to use their own judgment in the performance of their duties.

Rains, Utah. FRED TURNER.

Efficiency in Mine Management

Letter No. 2—It was with keen appreciation that I read the article entitled "Need of Efficiency in Coal Mining," *Coal Age,* Nov. 28, p. 983. Methinks that the author of that article was a dyed-in-the-wool sufferer from the inefficiency he has so aptly described. Satire is crude, except when handled by an artist; but this writer has described with the touch of a master the reasons why some men never become more than the bosses of antiquated "holes in the ground."

The description in that article, of the lubrication of the grandfather type of mine-car wheels, familiarly known as "self-oiling" or "ring-oiling" car wheels, took me back several years, in memory. Once again I stood upon the tipple of a mine, a few miles from Birmingham, Ala. Before me was an oiler with his gun in hand, and every time a car came on the tipple he would shoot, shall I say, a quart of oil at each wheel. His aim was not that of a marksman, and a constant stream of oil was dripping through the tipple floor beneath which was a great mound of "blackstrap," as they called the oil, and dirt, mute evidence of the waste.

Again, my thoughts reverted to a visit I made, some months ago, to a mine in West Virginia, said to be an "uptodate mine," where 3000 self-oiling car wheels are purchased every year to replace the wheels worn out in the service of a few hundred cars. Conditions underground were the average conditions found in coal mines. The waste, in this case, was due to the use of the wrong kind of equipment. Judging from the appearance of the superintendent of that mine, no one could tell him anything. His father and his grandfather before him had worried along with the same kind of equipment and why should he use anything else?

I was in the mood for revery, and a third time my thoughts wandered to a visit made to one of the largest mines in southern Illinois. Here, a huge pile of scrapped equipment was mute evidence of the lack of definite knowledge of the demands to be made upon it in the operation of the mine. The man in charge was one of the "know-it-all" type, and the company had paid for his exalted opinion of himself, many times over in a year.

My thoughts still wandered and, in imagination, I pictured to myself the man who thinks that he cannot use brakes on his mine cars, because his conditions are different from those of the mine just across the field. He does not realize that all of the time he is ruining good wheels by the practice of spragging his cars instead of employing a suitable brake.

Conditions Described Are Universal

Someone may think I am citing exceptional cases. My answer is, Go into almost any section of the country and observe the same inefficiency wherever you go. There is told the story of a mine in western Pennsylvania that has a haul of several miles. As the story goes, all of the four wheels on the rear car are spragged so as to hold the trip stretched to its full length. Sparks flew from each of the spragged wheels, and it is easy to imagine the four wheels ruined in each trip made in that mine.

Let us suppose each wheel weighs 100 lb. At a cost of 4c. per lb., the value of four wheels is $16. And, while we are at it, let us say that 100 tons of coal is hauled per trip. Then each ton of coal is taxed 16c. to pay for the ruined wheels. Fortunately, this undue expense is compensated for by the good results of other mines operated by the same company; but that does not excuse the waste mentioned.

Managing a Mine Not an Office Job

Speaking of efficiency, there are a large number of mines that are conducted along the right lines, though I fear many of these fail to use the right system of accounting, particularly in respect to mine haulage. I have in mind, at present, a mine in southern Illinois. The mine is in charge of a thorough-going conscientious man who, though not the owner, is a stockholder in the company.

This man learned long ago that, to achieve the greatest success, his job is not an office job. He makes daily inspections of all the mine equipment, including locomotives, coal cutters, mine cars, etc. When he observes a plank giving way, he sends the car at once to the shop for repairs. He gives particular attention to the running gear and takes up all wear by thrust washers, besides seeing that the wheels are lubricated, not oiled, at stated periods. The track is always in good condition.

One feature that, to my mind, is the solution of the whole question of waste is that the superintendent just mentioned finds time to become acquainted with his drivers, loaders and machine runners. He knows their habits and practices, and the results he has achieved prove that a coal mine cannot be managed from a swivel chair.

In coal mining, there are more avenues for leaks than in most other industries. A manufacturer knows the cost of his raw material and the labor put upon it, which, added to his overhead charges, gives him a real basis of computation. In contrast to this, a coal mine is operating a property bought or leased, perhaps a decade or more ago. It is often the case that this and other capital charges are ignored; and, as long as the selling price of the coal mined is kept a little above the cost of its production, the mine is supposed to be making money.

Efficiency in management calls for accurate accounting and only those managers who have the best system, keep their cars in the best shape, their motors in good condition and buy the best equipment obtainable are making the most on their investments. OBSERVER.

Philadelphia, Penn.

Perplexities of Mine Foremen

Letter No. 7—A short time ago, I was reading the letter of "Mine Foreman," *Coal Age*, Oct. 24, p. 793, regarding a dispute between a miner and his foreman, in respect to some bottom coal that a machine runner had left in the miner's room.

It appears that the foreman offered to pay the miner for the extra work of cutting out the bottom coal; but the miner said he would have to first see the committeeman working in the next room before he could go ahead and cut out the coal. I failed to see how this matter should perplex the foreman. He should not worry because the miner was willing to lose a little time. A car of coal more or less would not seriously affect the day's output of the mine.

The Pit Committee of a coal mine controlled by the miners' union sometimes oversteps its authority, and a miner is always willing to listen to the committee when it decides in his favor. However, no one committeeman has any right to act alone or to tell a miner what he should be paid. Such action can only be taken by the committee as a whole, whose duty it is to take the matter up with the foreman and make an agreement with him that would seem to be right in the matter.

While the miners' union have accomplished a lot of good, there are instances where they have led miners to believe that the miner cannot secure a square deal from a foreman, unless he works through the union and depends upon their activities to secure to him his rights. So often has it happened that a Pit Committee has made trouble for a mine foreman, that coal operators have absolutely refused to recognize the union, in order to protect their foremen from trouble arising from that source.

A few years ago, when I was working in the Diamond shaft, at Springfield, Ill., the drivers had a habit of taking off a large block of coal from the corner of a loaded car, so as to make a seat for themselves on the car. In cleaning up this coal, it was credited to the company to offset the expense of gathering it up. The miners demanded an average weight for the coal to be credited to themselves, but their demand was refused by the superintendent.

By vote of the miners, for three days afterward, the men loaded their cars only "bedded," which amounted to a loss of 1500 tons. The difficulty was then settled by the superintendent agreeing to make an allowance of 4 tons of coal a day to 150 miners. But, what may surprise some, the affair did not seem to worry the foreman in the least, as he had often been called to face greater difficulties than that.

A Superintendent's Lack of Wisdom

Another instance I recall where a good foreman was busy "on top," ordering much needed supplies of props, rails and ties that were to be sent down at once into the mine. The superintendent appeared and ordered the foreman to get into the mine himself and get out the coal, or get off the job at once.

On that occasion the foreman replied, telling the superintendent to go down the mine himself and get out the coal, and then quit. Had he chose to do so, the law would have upheld the foreman in going down and ordering every man whose place was in need of material to get out of the mine, until the material could be furnished.

There are perplexities for which mine foremen are themselves to blame. One writer has referred to miners roaming about the mine "looking for the boss." That will seldom happen when the boss performs his duty by the men. Most mining states have a law requiring the foreman to visit every man's working place at least once a day, while the man is at work. When the foreman does this there will be no necessity for miners roaming about looking for the boss.

Foreman's Work Not Done When He Goes Home

The real perplexities of a mine foreman come when he goes home and is kept busy away into the night, thinking out his plans for the next day. After putting in 10 hours of hard work in the mine, he has his cost-sheet to make up and a list of supplies to be given to the outside foreman, telling what is needed in the mine. Other lists for the cager, rope rider, stable boss, timbermen and trackmen, must be made out, and, after a good smoke, the foreman goes tired to bed.

Think of a good practical foreman carrying these responsibilities for which he is paid $6 a day when the poor devils he must watch to see that they do not get killed load their 12 tons of coal, at 83c. a ton, which brings them practically $10 a day, and we are face to face with some of the few perplexities of foremen.

Organized as a Foremen's Protective League, under the Federation of Labor, it might be possible for mine foremen to secure consideration for themselves; but, until that can be done, my advice is, Stay on the job and run your mine in compliance with the law. Keep a keen eye on the old and abandoned workings; allow no accumulation of gas, and do your duty by the men in your charge. As President Wilson has said, "*Be willing, no matter what your personal fortunes may be, to play for the verdict of mankind.*" It is an immortal saying and worthy of our following.

Farr, Colo. ROBERT A. MARSHALL.

INQUIRIES OF GENERAL INTEREST

Correct Accounting

During the past two years, much attention has been given to the proper method to pursue in estimating the cost of producing a ton of coal. But, yet, there seems to be quite a variance of opinion as to whether such items as mine cars, steel rails and ties, copper wire and wire hangers should be entered in the equipment account or charged direct to the operating account as supplies. I have held the opinion that these and similar items should be charged to the stock account as equipment, and the operating account should be charged, each year, with an amount showing the depreciation, as all such items have a life of several years and are available as assets until they are no longer fit for use. The same question has, no doubt, puzzled many other operators and accountants, and I would like to have their opinions and know their practice. ACCOUNTANT.

Matewan, W. Va.

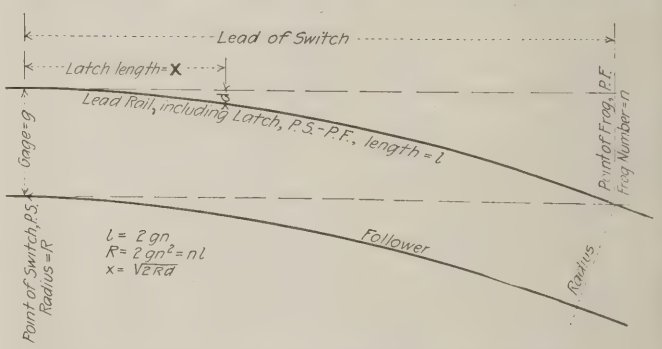
The proper accounting of mine supplies and equipment is truly an important matter. For lack of a proper charging of the numerous items that enter into the operation of a large coal mine, it has happened that the end of the year has more than once brought disappointment to the interested stockholder.

This correspondent is quite right in assuming that all supplies, machinery or other form of equipment that goes to form an integral part of the mine should be charged to the equipment account and a suitable amount for depreciation be entered each year as a charge to operating expense (profit and loss) and credited to equipment.

Wiring systems for telephoning, signaling or the transmission of power, ropes, piping, steel rails, steel ties or steel timbers are equipment, as they form part of the permanent fixtures necessary for the operation of the mine. They are chargeable to the equipment account, which should be credited with their depreciation. Repair supplies are chargeable to operating expense.

Lead Rail of a Mine Switch

Tracklayers, in coal mines, do not commonly have the training that enables them always to gain an intelligent idea of the meaning a textbook intends to convey. An instance of this is found in the description of a mine switch given in a leading mining textbook. I refer to Vol. 86 of the International Library of Technology, Sec. 48, p. 34.



In naming the different parts of the switch, the text reads, "The lead of a switch, or frog distance, is the distance measured on the main line from the point of switch to the point of frog." This would seem to mean that the straight rail of a switch is the lead rail. However, on the same page, the very next paragraph reads, "The lead rail of an ordinary mine switch is the turnout rail, lying between the rails of the main track, which refers, apparently, to the curved rail, reaching from the point of switch to the point of frog.

The reading of these two references leaves the impression that the same term, "lead rail," is differently applied in different switches, one being described as an "ordinary switch," while the other is, perhaps, a special form of switch. Speaking of this text, I overheard a good tracklayer remark, recently, "my work is to lay the switch down, and the book should use names that I know what they are talking about."

My own impression and understanding is that the term "lead rail" refers to the curved rail extending from the point of switch to the point of frog, or what I would call the "transfer rail." In mine practice, however, I always avoid the use of the term *lead rail*, preferring to speak of the *curved rail* or the *straight rail* of the switch, which causes no confusion. Will *Coal Age* kindly explain the true meaning of "lead rail."

———, W. Va. INSPECTOR.

Had our correspondent read more carefully the text of the volume from which his quotations are taken, he would have noticed that the first sentence he quotes is

ILLUSTRATING THE COMMON MINE SWITCH

speaking of the *lead of the switch*, or what is commonly called the "frog distance," or the distance the frog is ahead of the switch, as measured on the straight rail. This has nothing to do with the "lead rail" of the switch, to which the second quotation refers and which is the curved rail reaching from the point of switch to the point of frog.

The length of the lead rail is always greater than the lead of the switch, which is measured on the straight rail of the main track, from the point of switch to the point of frog, as clearly indicated in the accompanying figure.

In every switch, there are two curved rails and, in the main track, two straight rails. For this reason, the terms "curved rail," and "straight rail" are indefinite. There is only one lead rail in a switch. The other curved rail is often called the "follower rail." To understand correctly, one must read the text closely, or there is bound to be confusion.

EXAMINATION QUESTIONS

British Columbia Examination, Third Class, Dec. 17, 1918

(Selected Questions)

Ques.—Describe the precautions necessary in general shotfiring and name some of the conditions under which you would refuse to fire a shot or shots.

Ans.—In blasting coal, the charge of powder should be free to perform its work in breaking down the coal. The hole should not be drilled too deep and the shot should be properly mined or sidecut, and any projecting tops or bottoms should be removed before the shot is fired. The charge of powder should be no more or less than is required to perform its work, and this should be pushed to the back of the hole and thoroughly tamped with clay or road dust.

It is very important that coal slack or other combustible material should not be used for tamping. In firing with fuse, extra care is needed when tamping the hole, to avoid injuring the fuse, which might result in a misfire. In firing with squibs, the match should not be broken off or soaked in oil, or otherwise treated to hasten its burning. Care must be taken in removing the needle from the hole so as to leave a free passage for the squib back to the powder. Before firing, all accumulations of fine coal and slack should be removed and the place tested for gas. In a dusty mine, it is necessary to sprinkle the place before a shot is fired in that place or one adjoining.

A shotfirer should refuse to fire any shot that, in his judgment, is unsafe, or that he has reason to believe contains an overcharge of powder or is improperly tamped. Also, no shots should be fired where there is an accumulation of gas or dust in the place.

Ques.—Name and describe the various gases found in coal mines, stating where they are found and how detected and giving their specific gravities.

Ans.—The names and specific gravities of the common mine gases are the following: Methane, or marsh gas (CH_4), specific gravity, 0.559; carbon dioxide (CO_2), 1.529; carbon monoxide (CO), 0.967; hydrogen sulphide, or sulphureted hydrogen (H_2S), 1.192. Olefiant gas (C_2H_4), 0.978, is associated with methane in mines. The nitrogen of the air, specific gravity, 0.9713, is frequently the chief constituent of the blackdamp found in mines.

Methane is found where generated at the face or accumulated in pockets of the roof or at the face of rise workings and is detected by observing the cap formed on the flame of a safety lamp when this gas is present.

Carbon dioxide is mostly found in poorly ventilated or abandoned or other void places in the mine, or where it has accumulated in swags or at the face of dip workings in the mine.

Carbon monoxide is to be found in the products of slow combustion or gob fires existing in poorly ventilated places. It also is a constituent of afterdamp resulting from an explosion of gas or dust in a limited supply of air. Carbon dioxide is detected by observing its effect of dimming or extinguishing a lamp. Its presence is also made known by producing headache or nausea. Carbon monoxide can only be safely detected by observing its effect on small animals, as birds, or mice confined in a cage and exposed to the mine air where this gas is suspected.

Hydrogen sulphide is a dangerous gas which, though less common in mines, may be found in low damp workings where sulphur, in the form of pyrites, is present in the coal or adjoining strata. The gas is detected by its smell, which resembles that of rotten eggs.

Ques.—What are the principles involved in the safety lamp and what are the requirements for a good lamp for general use?

Ans.—The principle of the safety lamp is the isolation of the flame from the outside atmosphere, by means of a wire gauze chimney, all openings being protected with the same wire gauze. As long as the gauze remains cool, the gas-charged air passes through its mesh, and the gas is burned within the lamp. The flame of the burning gas is prevented from passing out of the lamp, by the cool metal. In passing out through the mesh, the gas is divided into streamlets and its temperature reduced below the point of ignition, which causes the extinction of the flame.

The requirements of a good lamp for general use are the following: The lamp must give a good light projected upward for inspection of the roof and downward on the floor. Its construction must be simple and consist of few parts that are easily and correctly assembled. The lamp must be strong for service and rough usage and not be too sensitive to gas so as to cause flaming in the lamp when little gas is present. It must be light and portable. A working lamp must be provided with a form of lock or fastening that will reveal any attempt to tamper with the same.

Ques.—At the commencement of your shift as a fireboss, you find the barometer unusually low and the water gage unusually high. What conditions in the mine are thus indicated, and how would you proceed under these conditions?

Ans.—The unusually low barometer points to a possible outflow of gas into the mine workings from abandoned areas and other void places in the mine and suggests a careful inspection of all the working places, wherever gas may be expected to accumulate, particularly the rise workings.

The unusually high water gage, assuming the speed of the fan is normal, would indicate some unusual obstruction in the air-courses, which hinders the flow of air and increases the resistance of the mine. Under these conditions, the fireboss must use extra precaution to discover the cause and take steps for the immediate removal of any obstruction or other cause he may find.

FOREIGN MARKETS AND EXPORT NEWS

Azores Islands Offers Chance for American Coal

The districts of St. Michael's and Fayal (Azores) showed a notable gain in imports during the year 1917 over those of 1916, in consequence of the increase of coal shipments to the ports of Ponta Delgada and Horta. The imports of coal at Ponta Delgada in 1917 amounted to 3,032,253 escudos (normal exchange value of the escudo is $1.0805), compared with 854,549 escudos in 1916; at Horta, 1,104,512 escudos in 1917, against 401,712 escudos in 1916; and at Angra, 10,638 escudos in 1916, but none in 1917. There was consequently a gain of 2,869,866 escudos in coal imports in 1917 over 1916. Practically all the coal was used for bunkers in supplying the demands of the largest number of ships that ever visited these island ports in a single year. The Azores, which are owned by Portugal, exports among other commodities alcohol, beans, pineapples, tobacco, sugar, tea, wine and mineral waters. Increased banking facilities have been offered to merchants to do business in American markets. If satisfactory shipping facilities are established, there ought to be a marked increase in commerce between the United States and the Azores. Though the market is small, there is no reason why American coal should not find a ready sale in the Azores, as it is a port of call for ships sailing to the Mediterranean.

Coal Scarcity in Greece

During the recent war the importance of an adequate supply of coal to Greece from outside sources was strikingly brought out on several occasions. It seems, from U. S. Consular reports, that there are lignite beds of good quality in the southern Peloponnesus. Permits for lignite mining have been granted by the Greek Government to various companies, but up to the present time mining operations are understood to have been conducted at a loss. This state of affairs seems to be due to lack of proper machinery and information as to the best methods of production, transportation, and so on; the cost of lignite became so high in the markets as to discourage its use, while a lower figure for the product would have involved the mine owners in even more serious loss. For these reasons all the mines except that at the city of Kardamyli have stopped operations, and this plant has an insignificant output. There is great demand for fuel by the railroads and other industries of Greece which at present consume quantities of wood either alone or with lignite. The Consular reports emphasize the demand for fuel and note the favorable opportunity for capital to invest in lignite mining. However, due emphasis is laid on the necessity of approaching the problems of mining, preparation and transportation on up-to-date lines in order to reduce the cost of lignite to a minimum.

Canada's Coal Supply

The coal consumption in Canada for the calendar year 1917 amounted to 5,319,688 net tons of anthracite and 29,497,375 net tons of bituminous—a total of 34,817,063 net tons. The anthracite coal is practically all utilized for domestic purposes. Only one mine in Canada produces a near-anthracite coal, and the tonnage from that seldom exceeds 150,000 tons per year. It is apparent, therefore, that Canada depends upon the United States almost entirely for anthracite coal.

The bituminous coal is used largely for industrial purposes. Out of the 29,497,375 tons of total consumption Nova Scotia produces 6,324,684 tons; New Brunswick 188,660 tons; Saskatchewan 355,304 tons; Alberta 4,723,139 tons; British Columbia 2,418,920 tons. This makes a total of 14,010,707 net tons, which leaves Canada indebted to the United States for the balance (after deducting 1,733,156 tons of coal exported from Canadian coal mines) of 17,219,824 tons of bituminous coal, or a total importation of 22,539,512 tons of the annual coal consumption of 34,817,063 net tons.

In an effort to relieve the fuel shortage Great Britain is releasing former workers in the coal mines of the Kingdom at a rate approaching 5000 a day. The coal shortage affects not only England's industrial reconstruction and the comfort of her householders, but that of several European states which have always looked to England for coal. Unlike conditions in the United States, which is rationed closer on anthracite than on soft coal, in London and elsewhere one may have two tons of anthracite in place of one of soft coal.

Market in South America for United States Coal

If the coal operators of the United States can compete with the British facilities in shipping by securing cheap bottoms, there is no reason why this country cannot obtain the coal trade of South America. Most of the coal used in South America comes from Cardiff, Wales, and points in Australia. There is a big demand for coal in Buenos Aires, Argentina, and in Montevideo, Uruguay, for bituminous coal for domestic and industrial purposes. A better effort will have to be made by American coal operators in the manner in which they handle their coal for shipment, as the cargoes from America in the past appear to be pulverized by the time they reach their destination.

Peru imports all of its coal for railroad purposes, and also for gas plants and other industries. Argentina consumes much coal on its extensive railroad system, as does Central Brazil.

Coal destined to points north of Valparaiso, Chile, is generally shipped through the Panama Canal, but for shipments south of that point it pays to ship around the Straits of Magellan, unless time is a consideration.

Coal Shortage in Germany

The coal situation in Germany appears to be causing some alarm. Owing to sickness among mine laborers and the sudden departure of the many prisoners who were working in the mines, the production in all districts has fallen far below normal. One report recently received from Essen is to the effect that the output of the mines in that vicinity is only about half the normal figure. A report from the same district, in the Norddeutsche Allgemeine Zeitung of Nov. 25, states that about 20,000 prisoners and other foreigners employed in the mines there have left since the signing of the armistice; and there has not yet been time to fill their places with demobilized troops. To a certain extent railway traffic also is disorganized. These conditions have caused such an acute shortage of coal in Berlin, for instance, that special measures are being taken to keep the consumption as low as possible.

Exports of Anthracite and Bituminous Coal and Coke, by Customs Districts and Countries—November, 1918

American Shipping Rates Cut

The U. S. Shipping Board on Jan. 27 announced a reduction in transatlantic freight rates to meet a cut made by the British Government. To Marseilles, Cette, Genoa and Naples the new rate is $1.60 per 100 lb., or 85c. per cu.ft. against the old rate of $75 per ton, rates based on weight or measurement at ship's option. The new rate to the United Kingdom is $1 per 100 lb. or 50c. a cu.ft., against the old rate of $66 a ton. The rate to Havre, Bordeaux, Antwerp and Rotterdam is $1.25 per 100 lb., or 65c. per cu.ft., against the old charge of $65 a ton.

Consular Invoices

The War Trade Board announces that the regulations contained in W. T. B. R. 409, issued Dec. 18, 1918, have been amended and that consuls have been instructed to certify invoices covering all unrestricted commodities without requiring evidence of the issuance of an import license and of the number thereof. In announcing this simplified procedure, the War Trade Board desires to impress upon importers that, for their own protection and to avoid the possibility that shipments may be made for whose importation license may be refused by reason of noncompliance with enemy trade regulations or for other reasons, they should secure import licenses before shipments are made.

COAL AND COKE NEWS

Harrisburg, Penn.

Particular attention was given by the United States subcommittee on manufactures, which is investigating the high price of anthracite coal and the alleged shortage of domestic sizes, to royalties paid by producing companies and to the cost of production.

Estimates by witnesses as to the cost of production ranged from $3.50 to $4.64 a ton, while the amount of royalties paid was said to be from 40c. to $1.30 a ton. It was testified that royalties, especially those paid to the Stephen Girard estate of Philadelphia, had steadily increased in the last five years.

A. C. Dodson, head of the Dodson Coal Co., testified that the royalties constituted about 23 per cent. of the selling price. On an investment of $2,000,000, he said his company had paid the Girard estate, since 1914, royalties of $1,873,000 on coal from 390 acres. He said the Girard estate was the barometer in determining royalties and that other owners, before leasing virgin coal lands or before making a new scale of royalties, invariably gaged their prices on what was charged by the Girard estate.

"Every time wages are increased or any other factor aids in boosting the price of coal, the Girard estate collects on it," commented Senator Jones.

Mr. Dodson estimated roughly the cost of producing a ton of coal at $3.50, while the estimate of Charles Dorrance, operating head of the Hudson Coal Co., was $4.64. A. B. Jessup, general manager of the G. B. Markle Co., told the committee the average cost at his mines in the Hazleton region was $3.80 a ton with a reduction of 30c. paid in royalties. Of this cost, he said, 30 per cent. represented the labor charge.

Mr. Jessup said the rate of royalties was regulated the same as for any other commodity, by the highest price the coal land owner could get for the lease on his lands.

T. Ellsworth Davies, a Scranton coal mine expert, estimated that there are about 23,000,000,000 tons of unmined anthracite in the Schuylkill County fields. At the present rate of mining, he testified, this coal will not be exhausted for 900 years.

Uniontown, Penn.

The Regional Fuel Administration, the agency which directed the mobilization and regulation of the Connellsville coke region for the part it played in the war, will be discontinued on Feb. 1 when price restrictions and the zone system of distribution are removed. With the closing of the regional fuel office the industry is returned to a normal basis, and operators and producers generally are prepared for the occasion.

Since May, 1918, when statistical reports of production were first compiled, the output of the Connellsville region has totaled 11,660,368 tons of coke and 6,812,027 tons of coal, or an aggregate production of 24,302,579 tons. Removal of fixed prices is expected to create a steady market, and operators are planning a curtailed production for a few weeks until conditions become more settled in order that an oversupply will not be secured to beat down the market.

Production of coal and coke in the Connellsville region for the week ending Jan. 17 reached its highest figure since the ending of the war. Figures issued at the office of the Regional Fuel Administration show an aggregate output of 631,099 tons, an increase of 64,561 tons over that of the preceding week. Coke was 290,465 tons, an increase of 19,550 tons, and coal shipments were 195,391 tons, a gain of 24,976.

During the present period of uncertainty repairs will be made to ovens and plants in preparation for the spring rush. Coal has been "off color" in the market since the first of the year; but the removal of prices finds the demand for coke active, although some "spot" was sold this week for $5.25.

Charleston, W. Va.

The removal of zone restrictions and the freedom from tidewater embargoes is conducive to operations on a larger scale in the New River district. Vessel space appears to be more plentiful, and consequently congestion at tidewater points has been relieved. A large tonnage of New River coal is now being absorbed by the Navy. With the Western markets now open to them, New River mines will begin within a week or so to ship coal to the West, zone restrictions having prevented that heretofore. In view of the fact that miners and operators are getting ready for the wage conferences for the coming year, labor conditions are somewhat unsettled.

"No market," and a labor and car shortage, was responsible for a decrease in production in the New River and Pocahontas district. The total production was 335,931 tons, this being a gain of about 35,000 tons over the previous report. Even though the market for Pocahontas coal has been somewhat limited, partly attributed to zone regulations, prices have been maintained and it has been found difficult to secure enough men to man some of the larger operations.

Impetus will be given operations and consequently production, to some extent at least, in the Kanawha district following the removal of the ban on shipments into certain zones, and more coal will move westward in the future. The full effect of the Fuel Administration's latest order will not be felt, however, for a time, owing to the fact that there is plenty of coal on hand in the West; but there will undoubtedly be, in the opinion of Kanawha operators, some stimulation of trade in the Kanawha region. Production during the week ending Jan. 18 reached 107,785 tons.

It continues to be a peculiarity of conditions in the Fairmont region that although there is no longer any imperative demand for coal, yet transportation facilities have been better in the region than at any time in the last twelve months. There was furnished to the mines of the district during the weekly period ending Jan. 18 with clock-like regularity, not less than 2300 cars on any one day, more than the mines of the district succeeded in loading. There was, during the same period, a healthy demand for the product of the Fairmont district, the bulk of the coal mined being shipped eastward. Prices are being maintained even with a somewhat diminished demand.

Once again loss of production is larger than actual production in the Logan mining district, as the production report for the week ending Jan. 18 shows. The total output only reached 149,829 tons, while the production loss was 172,384. By far the largest part of the loss was due to no market, such a loss amounting to 139,776 tons, other losses outside of that from car shortage being comparatively small.

New York, N. Y.

Wilbur A. Marshall was elected president of the Wholesale Coal Trade Association of New York by the Board of Directors of the organization on Jan. 21. Mr. Marshall succeeds George M. Dexter, of Carpenter & Dexter, who declined reëlection.

At the annual meeting of the association, which was held in the Whitehall Club, reports read by Charles S. Allen, the secretary, and by C. C. Harris, the treasurer, showed the organization to be in a flourishing condition.

Addresses were made by E. A. de Lima, president of the Battery Park National

Bank, who spoke on trade acceptances from a banker's standpoint; by George H. Cushing, managing director of the American Wholesale Association; and by Major W. R. Coyle, a member of the Board of Directors of the Association, who had just returned from France where he served with Uncle Sam's forces.

The election of directors resulted in the following being chosen: W. S. Alden, W. R. Coyle, George M. Dexter, E. Kelly Downey, C. C. Harris, J. M. Leonard, W. A. Marshall, Howard C. Matlack, Charles A. Owen, Gardener Pattison and LeBaron S. Willard.

Besides M. Marshall, as president, the Board of Directors elected the following officers: Vice President, Charles A. Owen, to fill the vacancy caused by the resignation of Mr. Willard; treasurer, C. C. Harris. Mr. Allen will continue as secretary.

Mr. Marshall, the newly elected president, is a well known member of the coal trade. He is president of W. A. Marshall & Co., the Lincoln Coal Co. and the Wolf Den Coal Co.

It is understood that the change in assessing demurrage charges as recommended by the Bituminous Operators' Committee of the Association ["Coal Age," Vol. 15, No. 4, page 186] will be put into effect on Feb. 1, and that the Tidewater Coal Exchange will take up the matter of coal classification schedules at its meeting on Jan. 31.

PENNSYLVANIA

Anthracite

Williamstown—The dead body of Charles Barry, fireboss at the Susquehanna Coal Co.'s colliery, who was buried in a rush of coal, was found several days later by rescuing parties that had been working since the time of the accident. Charles J. Price, state mine inspector, of Lykens, was badly bruised in a fall while aiding in the search.

Mauch Chunk—The Anthracite Forest Fire Protective Association, which is composed mainly of coal corporations and large woodland owners, both private and corporate, is undertaking to protect 70,383 acres of forest land from destruction by forest fires. This land is almost entirely located in Carbon, Schuylkill and Luzerne Counties.

Summit Hill—Many old-time and practical miners are predicting that the present method of digging coal underground will soon be superseded altogether by stripping. The Lehigh Coal and Navigation Co. is at present placing another large steam shovel at a point about 500 ft. up the mountain here, where a large stripping operation will be started.

Wilkes-Barre—The Lehigh Valley, Traders', Central, Wilkes-Barre and Hudson companies have been indicted on the first indictment of its kind for damage to surface property and must stand jury trial for injury wrought by mine caves in Plains township. The action against the companies was brought by the Township commissioners after several streets had been damaged by caves.

Shenandoah—The cage in the Hammond Colliery shaft jumped the guides on the morning of Jan. 21, tore and crushed the shaft timbers out of place for many yards and hurled the large timbers to the bottom. Considerable damage was caused and the colliery was forced to suspend, throwing 1200 men and boys idle. Only the fact that coal was being hoisted at the time the accident occurred accounts for no loss of lives.

Wilkes-Barre—The Lehigh & Wilkes-Barre Coal Co. has given notice that every man who left the service of the company to take up arms for the country will be given his old position. C. F. Huber, the president and general manager, announced that returning soldiers and sailors have only to inform the mine foremen under whom they worked of their desire to return. There are 24,000 jobs open for mine workers in the anthracite fields. Ten hundred and seventeen men formerly employed in the anthracite region are scheduled for early release from military camps.

Hazleton—J. S. Wentz & Co. are arranging preliminary plans in connection with the large tract of coal properties recently acquired at Raven Run. It is understood that the present operating company holds a lease for about another year, but the Wentz company will perfect its plans to take over the tract as soon as available. In connection with the proposed work, a new breaker will be erected, with other structures, the mines to be electrically operated throughout. It is also understood that the company is considering the development of a new townsite at the operation

Glen Lyon—Thomas M. Cooper and Morgan Thomas received burns in an explosion of gas in No. 2 shaft of the Alden Coal Co., on Jan. 18, which resulted in their deaths at the Nanticoke State Hospital.

Pottsville—For the first time since the beginning of the world war, coal is now accumulating in the anthracite region. The Philadelphia & Reading Coal and Iron Co. has begun filling up the bins in the big storage yards at Landingville, and three of the big "pockets" which extend down the moutain side are already filled with coal. The only coal being stored, however, is of the steam sizes, and if this coal continues to accumulate a number of coal washeries will be closed down, as they produce steam sizes of coal almost exclusively.

Carbondale—Under the terms of a settlement reached by counsel at the opening of court Thomas Calacuis, who was injured while at work in a Hudson Coal Co. colliery, is to receive $2800 damages from the company, while his father is to get $450. Attorneys representing the boy contended that he was under fourteen years of age at the time of the accident, and that he should not have been employed.

North Scranton—Recently the New York courts awarded the heirs of the Rockwell and Gilbert families, owners of coal underlying a considerable portion of the city, back royalties in the sum of $429,000, the heirs having charged that the Delaware & Hudson Co. had failed to pay for small sizes mined. At the time the suit was instituted the plaintiffs asked for forfeiture of the lease, and also won on this point. Although the Delaware & Hudson promptly appealed from the decision, it has since opened negotiations with the Rockwell and Gilbert heirs for a settlement of the case. It is understood that the company would like to either renew the lease or execute a new one, and others, notably the Scranton Coal Co., it is reported, would like to secure the lease. The tract of land being mined comprises 325 acres and is said to be rich in coal, being mined through the Leggitt's Creek shaft.

Mount Carmel—Plans for the electrification of all the anthracite mining operations owned by the Susquehanna Collieries Co. in the Mount Carmel-Shamokin coal fields, the power to be generated at one central plant, are about completed and the work of construction will begin shortly. The big plant, which will cost several millions of dollars, will be located at Green Ridge, near the Pennsylvania colliery, engineers having recently laid out the site of the building. The ground is already cleared. From the power plant high tension wires will be strung to the Richards, Pennsylvania, Scott, Hickory Ridge, Hickory Swamp, Luke Fidler and Cameron collieries. At all these operations electrically driven machinery will supplant that now used in the operation of slopes, shafts, planes and breaker machinery, and the steam plants now in operation will be done away with.

Larksville—No. 5 breaker of the Delaware & Hudson Coal Co. was totally destroyed by fire on Jan. 21 and 2500 men and boys are temporarily idle. The monetary loss is difficult to estimate, but company officials are of the opinion that the breaker can be replaced in about six months at an expenditure of $500,000. The work of rebuilding will begin immediately, according to instructions received from heads of the company in New York. The destruction of the breaker, which handled the daily output of 4000 tons of coal from five west side mines, has necessitated the shipment of this huge amount of coal to the Baltimore colliery at Wilkes-Barre, and Coal Brook and Powderly breakers near Carbondale, which work, it is believed, will be started within ten days. The fire originated in the preparing room about 7:45 a.m., and was caused by sparks from an overheated motor igniting the woodwork.

Wilkes-Barre—"We are beginning to read the handwriting on the wall and are investigating possibilities and probabilities," said F. M. Chase, general manager of the Lehigh Valley Coal Co., recently, when asked if the Lehigh Valley is considering shutting down some of its collieries, because of the slackness in the demand for anthracite. It is reported that at a recent meeting of company executives the question of shutting down several collieries in each district where the production cost is highest was discussed, with a view to adopting this expedient if the market should become so dull as to warrant it.

Bituminous

Johnstown—Thomas Currie, of Nanty-Glo has purchased for $50,000 the Finesome coal mine at Confluence, Somerset County, the deal including tipple, buildings and a lease on 200 acres of mineral. The property was formerly a part of the holdings of Cosgrove & Co., of Johnstown.

Uniontown—The four miners entombed on Jan. 20, in the Mt. Braddock mine of the W. J. Rainey Coal Co., are alive. On Jan. 22 they were rescued by teams from the H. C. Frick Coke Co. and the Central Connellsville Coke Co., led by State Mine Inspectors Richard Maize, E. E. Girod and William Langan, who had been in the mine day and night to reach them. The miners killed on Jan. 20 died from asphyxiation in an attempt to release the entombed men, who had been cogging in the affected section of the mine. About 4 a.m. on Monday, Jan. 20, a large rock and refuse bank which was afire dropped into the mine, due to a cave-in, and set fire to a portion of the workings.

WEST VIRGINIA

Glen White—Construction work will be begun on a large tipple for the E. E. White Coal Co. within the next few months, engineers having virtually completed surveys and other preliminary work in connection with the erection of the structure, which will be most completely equipped.

Bluefield—Fire completely destroyed the Norfolk & Ungle tipple of the Pocahontas Fuel Co. at Switchback on Friday, Jan. 17, but while the fire resulted in a total loss, the company was protected by insurance even covering loss of profits, cost of operation, etc. The destroyed tipple, one of the largest in the Pocahontas coal fields, will be replaced by a steel structure.

Logan—The general store building as well as several dwellings owned by the Standard Island Creek Coal Co. were completely destroyed by fire at Taplin, W. Va., on Thursday, Jan. 16.

Morgantown—Operations at the Bertha mines of the Quality Cement Coal Co. in Monongalia County, one of the largest operations on the west side of the Monongahela, were suspended at the last p
It is not known when the company will resume the mining of coal. Nearly all o
the mines in that section, except the North American, have shut down, and miners in the community are idle. Conditions are similar along the Morgantown & Kingw
R.R., and in other coal mining sections of the county.

OHIO

Carrington—The Sunday Creek Coal Co. and allied interests are erecting a new tipple at Mine No. 9 at this place. This is one of the largest mines of the company and is located on the Zanesville & Western R.R. The Ohio Collieries Co., operated by the George M. Jones Co., of Toledo, is also making many improvements.

INDIANA

Terre Haute—The Indiana Bituminous Coal Operators' Association, with headquarters here, has advertised a reward of $1000 for information leading to the conviction of persons responsible for surface mine fires, most of which were believed to have been of incendiary origin the past year. There were a number of serious surface mine fires the past twelve months.

ILLINOIS

Herrin—The Pond Creek Coal Co.'s mine has been sold to D. E. McMillan, Chicago, and James C. McElvarn, of Springfield, for $250,000. The property consists of 1000 acres, with an output of 1500 tons a day. It employs 250 men.

Pekin—The Tazewell Coal Co. has filed an appeal in the Illinois Supreme Court against the Illinois industrial commission and Mrs. Matina Lipnick, administratrix of the estate of her deceased husband, Andrew Lipnick, who was killed in the mine of the Tazewell Coal Co., to review the judgment of the Tazewell County circuit court, which gave Mrs. Lipnick damages for the death of her husband.

Springfield—The Peabody Coal Co. has in the past year completed two holes, each 426 feet deep, and 18,546 tons of coal have been hoisted at a rate of 300 tons daily. There are now 125 men employed in the mine. Eventually there will be 4500 tons of coal hoisted daily and 750 men will be on the pay rolls.

Bloomington—The Chicago & Alton R.R. has begun the storage of 50,000 tons of coal at various points. This is done in anticipation of a possible shutdown of Illinois mines Apr. 1. Reserve supplies of coal are being stored at Chicago, Bloomington, Springfield, Roodhouse and other points.

Belleville—The temporary injunction obtained in the Circuit Court recently by the Missouri-Illinois Coal Co. against the White-Sergent Coal Co., restraining it from abandoning the mine at Rentchler Station which it has been operating under a lease from the Missouri-Illinois company, has

been dissolved. The injunction was obtained on the representation that the White-Sergent company had violated the agreement to operate the mine continuously and that accumulating water was destroying the equipment. The dissolution was granted when it was shown that the White-Sergent company had given notice of intention to discontinue operation in December, and that when the injunction was obtained it had men pumping the water out of the mine.

KENTUCKY

Earlington—The St. Bernard Coal Co. is erecting a large power house at its plant here.

KANSAS

Cherokee—Fire at the plant of the Hamilton Coal Co., Shaft No. 6, recently destroyed a portion of the tipple and the chutes. The total loss is estimated at approximately $50,000.

Foreign News

Quebec—Never in the history of navigation on the St. Lawrence has a steamer left Quebec for the open sea so late in the season as the Canadian "Voyager," which departed on Jan. 22 for Halifax and then overseas. The St. Lawrence is ordinarily ice locked here at this time of year.

Victoria, B. C.—The Rocky Hard Coal Co., which has large interests in what is known as the Alberta Coal Branch of the Grand Trunk Pacific, are actively operating on a large hill of coal which extends 60 ft. above the level of the railway tracks, coal being taken from a facing of about 400 ft. The field is located near Coalspurstation, 47 miles south of the town of Edson. The coal is of good quality and is being shipped as far east as Winnipeg. Its accessibility is indicated by the fact that steam shovels are being used in loading the coal directly from the coal beds into the cars.

Nanaimo, B. C.—A verdict has been given by the Coroner's jury before which an inquest was held into the cause of the death of 16 coal miners at Nanaimo, B. C., on September 10 last. It reads as follows: "We, your Coroner's jury, empanelled to inquire into the death of Robert Kelly and 15 others in Protection Shaft, of the Canadian Western Fuel Co., Sept. 10, 1918, find that the said men came to their death by descending on a defective cable, which broke, owing entirely to the oxidizing of the wires, chiefly caused by apparent absolute lack of any internal lubrication, leaving the wires thus exposed to the action of a more than normally corrosive water and a humid atmosphere. In view of the evident general unreliability of exterior lubrication measures, which from the evidence adduced failed to preserve to any very appreciable extent the life of said cable or preclude against deterioration, we suggest that the Department of Mines recommend the appointment of an expert inspector of hoisting ropes, cages, safety catches and all appurtenances generally, and that legislation be enacted whereby under such abnormal conditions as obtained in said shaft no new hoisting cable be retained in service longer than some reasonable time to be determined by the Department of Mines, as otherwise there would appear to be no practicable process which can be adopted and absolutely relied upon looking to the absolute dependability of such hoisting cables against defect or breakage under all present governing conditions."

Personals

R. G. Rees, formerly in the coal business in Lima, Ohio, has been made sales manager of the Maple Hill Coal Co., of Columbus, Ohio.

J. A. Cameron, recently returned from service in France, has accepted the position of superintendent of the Ellsworth Collieries Co., Ellsworth, Penn.

M. L. Carriger has been succeeded as superintendent of the Midland Coal Co., of Barbour County, by **E. S. Walfesberger.** Mr. Carriger will return to the Pocahontas fields, where he previously held an executive position.

Clarence H. Robbins, general inside superintendent of the West End Coal Co., has resigned his position to take effect Feb. 1. Mr. Robbins has been connected with the West End interests for more than forty years, and has had charge of the inside workings for over thirty years.

Thomas J. Davis has been named sales manager of the Producers' Coke Co., the largest brokerage concern in the Connellsville coke region, to succeed Wiley L. Byers. During the war Mr. Davis, in the capacity of assistant to Mr. Byers, had virtual charge of the sales department of the Producers' Coke Co., while his superior was

THOMAS J. DAVIS

engaged in Fuel Administration activities. He is a practical coke man of several years' experience and is also familiar with the railroad end of the business, having been chief clerk in the coal and coke office of the Pennsylvania R.R. at Uniontown, Penn., for a number of years prior to his employment by the Producers. The Producers is the selling agency for many independent operators and does an annual business of from $6,000,000 to $8,000,000.

R. E. Butler, superintendent and engineer for the Benoit Coal Mining Co., has resigned his position and opened an office in Jasper, Ala., as consulting and mining engineer. Mr. Butler, before joining the Benoit company, was for seven years chief engineer for the Republic Iron and Steel Co. in Alabama.

C. B. Stewart has been appointed general superintendent of the Coal Bell Coal Co. operations at Bentree, W. Va. Mr. Stewart has been identified with the coal-mining industry in the Kanawha and New River districts for several years, and has a broad general knowledge of electrical and mechanical coal mining.

Thomas W. Davis, commissioner of the Michigan Coal Operators Association, has resigned his position, to become effective Mar. 1. Mr. Davis, who has been commissioner since 1901, with the exception of one year spent in the West, was from 1887 to 1899 in various positions of responsibility with the mine workers' organization.

William T. Grier has resigned as secretary of the Anthracite Committee of the United States Fuel Administration effective Feb. 1. The work of the Anthracite Committee has become greatly lessened since it became possible to permit free distribution of all sizes of anthracite other than stove and nut. Prior to becoming secretary of the committee Mr. Grier was connected with the Lehigh Valley Railroad Co. in New York City.

Industrial News

New York, N. Y.—The incorporation of William Farrell Sons, Inc., of this city, was announced in Albany on Tuesday, Jan. 28. The corporation, which will deal in coal, wood and ice, is capitalized at $12,000,000, and will have $4,000,000 eight per cent. cumulative preferred stock, par value $100.

Pittsburgh, Penn.—The Beckwith Machinery Co. has opened a Cleveland office at 1227 West 9th St., in charge of E. G. Stoner, assisted by C. Z. Dally, of the Pittsburgh office. The Beckwith company handles hoisting engines, concrete mixers, engines and boilers, and expects to carry a complete stock of such equipment in Cleveland, as well as in Pittsburgh.

Brownsville, Penn.—At the annual meeting of Snowden Coke Co. in Pittsburgh, Penn., on Jan. 16, Charles Snowden, of this place, resigned as president of the company, and Isaac Taylor, of Uniontown, general manager, was elected president. The operations of the company are near Brownsville on the Redstone branch of the Pennsylvania R.R., and consist of a large mine and 300 Mitchell rectangular coke ovens.

Washington, D. C.—The second offering of unsold portions of the coal and asphalt segregated deposits in the Choctaw and Chickasaw Nations will be made between Sept. 15 and Nov. 15 of this year in place of December and January, 1920, under terms of the Indian appropriation bill ordered reported to the House on Jan. 14. Only one-tenth of the tracts were taken at the first sale. It is provided that at the second sale the deposits must bring the appraised value, as in the first sale.

Columbus, Ohio—E. E. Learned, who was in charge of the office of the Hisylvania Coal Co. and allied interests during the absence of Secretary E. W. Blower, has been made sales manager and purchasing agent of the concern. The company has moved its offices from the twelfth to the sixteenth floor of No. 8 East Broad St., which give additional space. The former offices of the company have been occupied by the Consolidated Mining Co., which moves from the Columbus Savings and Trust Building.

Jefferson City, Mo.—The Workmen's Compensation bill to be introduced in the House for the State Federation of Labor has been modified to meet objections of employers. Under the modification it will provide a "waiting period" of three days before compensation shall be paid for any accident. The employers have also prepared a bill to be introduced, but sponsors for the Federation bill hope to make it so nearly acceptable to the employers that they will not push their own bill vigorously.

Louisville, Ky.—The rapid motorization of large retail coal company delivery equipments was shown a few days ago when the Byrne & Speed Coal Co., of Louisville, advertised the following items: "For Sale—14 coal wagons and carts; seven double sets of harness (almost new); 14 head of mules." This company is using Federal trucks in delivery. The Atlas Coal Co. went exclusively to motors, was unable to find a market for the carts, and burned them in its yards, realizing more for the metal before peace was declared than it could for the carts.

Charleston, W. Va.—Deaths in the coal mining industry of the State of West Virginia in December totaled 34, all except four of such deaths being inside mines. Deaths from falling roof and coal continue to lead all other causes, there being 13 during December. Seven deaths were caused by mine cars and five by motors. One casualty was caused by a premature explosion and four by a local gas explosion at Havaco. Outside the mines one fatality was caused by a mine car, two by motors. The largest number of deaths was in McDowell County. Of those killed, 21 were Americans and 13 were foreigners.

New York, N. Y.—Cosgrove & Wynkoop, Ltd., which recently opened offices in the Singer Building, is developing a large export trade. This firm was organized early this year. Mr. Wynkoop, the president is well known in the coal trade, having been connected with Watkins & Co.; while the other member of the firm is John C. Cosgrove, the Johnstown operator. He is the treasurer of the firm. Other officers are H. J. Meehan, vice president; A. Kemmerer Cosgrove, manager of the Philadelphia office of Cosgrove & Co., is the secretary. The firm has an export loading capacity of 2000 tons per day and is the sole export agent of the Lenox Coal Co., Homer City Coal Co., Ernest Coal Co. and Thermal Smokeless Coal Co. It also handles New River and Pocahontas coals and anthracite.

Fairmont, W. Va.—Under a reorganization of the Fairmont and Cleveland Coal Co E. A. Russell has been elected secretary of the company to succeed J. F. Straight who resigned. The new secretary has for several years been the manager of the Twin Mountain Orchard Ry., and prior to that was connected with the Consolidation Coal Co. The officers of the company as now constituted, are W. E. Watson, of Fairmont, president; E. F. Hartley, of Fairmont, first vice president and attorney; Friend Cox, of Wheeling, second vice president; John W. Poling, Fairmont, third vice president; Glenn F. Barnes, treasurer. The Rosebud Fuel Co., which was operated as a sales company for the Fairmont & Cleveland Co., will be dissolved and hereafter the company will handle all sales matters. The Fairmont & Cleveland Co. operates on Parkers Run, Marion County.

MARKET DEPARTMENT

Weekly Review

What Market Conditions Will Be With Elimination of Government Control Open to Conjecture —Some Price Cutting on Medium Grades of Soft Coal—Practically No Demand for Anthracite.

WITHIN the next few days the bituminous coal industry will find itself functioning as it did in pre-war times, for on Feb. 1 all the handicaps and restrictions imposed by Federal control during the past two years will have been removed. Market conditions in the near future will as a result be determined solely by the manner in which the producer and consumer of soft coal react to the new-found freedom.

It is impossible to conceive of the coal industry returning again to price-cutting and cutthroat competition; and large purchasers who purposely kept out of the market in recent months, in the belief that when Government control ceased they could name their own price for fuel, will find that the old order has passed, never to return.

The elaborate system of reports required by the Federal Fuel Administration during the war period has taught many operators their true cost of production, a knowledge that was woefully lacking before the Government took hold of the industry. With wages as high as they are at present, and the cost of material and equipment still "in the clouds," coal will hardly be cheaper. If the consuming public will not pay a price for coal that will enable the operator to make a legitimate profit, the coal will not be mined. Already a great number of operations have shut down rather than work at a loss, and instead of paring down prices to meet the figures set by purchasing agents many mine owners have signified their intention of doing likewise.

It cannot be overlooked, however, that at the present moment fair-to-poor grades of bituminous coal are being offered here and there at prices considerably lower than the Government maximums. The overstocked condition of the market, the closing down or restricted operation of many factories and the phenomenally mild weather are factors that tend to work counter to the best interests of the coal mining industry. High-grade bituminous coals continue to maintain their price levels, with a strong probability that they will go higher with the elimination of Federal price control.

Retail demand for anthracite is practically nil, for reasons that are obvious. The one-third withheld from consumers by the fuel authorities early in the year in most cases is now not wanted. In the majority of instances original applications were padded, the two-thirds delivered representing virtually the entire season's requirements.

WEEKLY COAL PRODUCTION

Bituminous—The production of bituminous coal in the week ended Jan. 18 is estimated at 9,943,000 tons, a decrease of 423,000 tons compared with the week of Jan. 11, but an increase over the same period of 1918. The daily average in the week of Jan. 18, 1919, is estimated at 1,657,000 tons, compared with 1,422,000 tons the same week of 1918 and 1,738,000 tons in 1917. Production in January, 1917, was not hampered by storms such as were encountered in January, 1918, nor by lack of market as this year, as many consumers are using coal from storage accumulated last summer, and production is probably less than current consumption.

The estimated production of bituminous coal from Apr. 1, 1918, to date is 476,563,000 net tons, an increase of nearly 36,000,000 tons over the corresponding period of 1917-18.

Anthracite—Estimates of the production of Pennsylvania anthracite show continued improvement in the output which, for the week of Jan. 18, 1919, is 1,786,000 net tons compared with 1,651,000 tons the corresponding week of 1918. Although production during the coal year to date is more than 1,500,000 tons less than corresponding period of 1917-18, the current needs of the country for anthracite are apparently being fully met, because of the careful distribution of domestic sizes by the Fuel Administration and the warmer weather this winter compared with last winter.

New England Shipments—Shipments of coal to New England in the week ended Jan. 18, both by all-rail and tidewater, increased over the week ended Jan. 11. Baltimore was the only port to show a decrease. Shipments through rail gateways were nearly 116,000 net tons, compared with 106,000 tons the week of Jan. 11 and 195,689 tons average weekly Apr. 1, 1918, to Jan. 18, 1919. Tidewater shipments were 195,000 tons, compared with 149,400 the week of Jan. 11 and 321,565 tons average for the coal year to date.

Tidewater Shipments—Bituminous coal dumped at North Atlantic ports in the week ended Jan. 18 was 706,000 net tons, an increase compared with 561,565 tons the week of Jan. 11 of 144,500 tons. Baltimore recorded a decrease, but both New York and Philadelphia and Hampton Roads had substantial gains.

Beehive Coke—The production of beehive coke in the week of Jan. 18 is estimated at 557,000 tons, the third successive increase over the low record of Christmas week. Operators in the Connellsville, Greensburg and Latrobe districts reported operation at 76 per cent. of railroad rated capacity, an increase of 72.6 per cent. over the previous week. Production of beehive coke in these regions is reported as 334,431 net tons and shipments of 160,950 tons of coal.

Byproduct Coke—The production of byduct coke in the week ended Jan. 18 was 553,610 tons, an increase over the week of Jan. 11 of nearly 26,000 tons. This increase was due, in part, to increased capacity and better demand for coke, and repaired plants. Increases in capacity were reported from Pennsylvania, where additional ovens were operated at the new Clairton plant, and in Colorado and at Youngstown, Ohio. The percentage of capacity reached in the week of Jan. 18 was 83.9, compared with 81.0 per cent. the previous week. Various reasons were assigned for the increase from 4.5 per cent. to 7.7 per cent. in capacity lost for other causes, among others delay occasioned through transportation difficulty in getting empty cars placed for loading.

BUSINESS OPINIONS

Dry Goods Economist—Readjustment of selling basis of cotton fabrics continues. Prices of well known lines of bleached cottons, wide sheetings, pillow tubings, tickings, outing flannels, ginghams, madras and chambrays have been cut by mills and their selling agents. The attitude of labor in textile plants and in the cutting-up industry is becoming a source of grave concern. Demands for decreased hours of labor are heard on all sides.

Bradstreet's—The trade situation, though slack, is not without redeeming features, and there is enough sunlight to prevent an unrelievedly gloomy picture being painted. Perhaps the most encouraging feature from the standpoint of the long-suffering consumer is the continuance of the declining tendency shown in food prices. While this tendency is most manifest in butter, cheese and eggs—dairy products, in short,—and mild weather and cancellations of our own and Allied government orders may be chief reasons therefor, there is little disposition to question the cause in view of the agreeable effect.

Iron Trade Review—In Pittsburgh, steel works are operating at an average of 70 per cent. capacity. About thirty blast furnaces have been blown out in the East, and South Buffalo furnaces are again becoming a powerful factor in the New York pig iron market, owing to the fact that the freight rate from Buffalo to the metropolitan territory is lower than the rate from Pittsburgh. Inquiries for 5000 tons of foundry iron for delivery during the first half are now pending in New York. Moderate export activity continues. Japan, which is actively pushing its shipbuilding program, has placed 35,000 tons of plates in the Chicago district and ordered 10,000 tons of pig iron.

The Iron Age—With new bookings less than half of current production, the industry is measurably nearer the moment of total deflation from the war basis. In many lines of finished steel there is not much over a month's work ahead. The encouraging feature from the buyer's standpoint is that labor now idle shows a disposition to resume at reduced wage rates and firm offers for steel at below present levels are now the more likely to lead to successful negotiation. January pig iron production will be considerably below that of December. A downward revision of coke prices, seeing that Federal control will be relinquished Feb. 1, and that capacity is now much greater than demand, is a factor in the readjustment.

Marshall Field & Co.—Current wholesale distribution of dry goods is in excess of the same week of 1918. The total of road sales for immediate delivery also was greater compared with a year ago. Fall lines have not yet been opened. Retailers are stimulating their sales most effectively and are rapidly reducing their heavy stocks. They are buying from hand to mouth to replace sold out merchandise and are not making any heavy purchases as during the past seasons. The radical reduction in the prices of staple cottons together with the revision downward in gingham prices has given more confidence to the trade generally. More customers were in the house, compared with the same week of 1918. Collections continue good.

American Wool and Cotton Reporter—Reductions in wool prices have already taken place, but discussion has created an impression among buyers that great concessions can still be made. It is natural for prices to decline when the demand is relatively small, but since the Government has established the new low prices for raw material, it would seem unwise to expect quotations for cloth to be figured upon any lower raw material basis. Buyers of cotton goods are not satisfied that the low market levels have been reached, since cotton has not declined in a way to compare with the decline which has occurred on goods. The attitude in regard to guaranteed prices shows that buyers are uncertain as to the course of the market.

Dun's—For nine weeks running, recessions have outnumbered advances in a representative list of wholesale quotations, and in retail channels, where accumulations of merchandise have resulted partly from unseasonable temperature over a wide area, some offerings are being made at material concessions. But while certain markets have been lately turning downward, and though efforts to stimulate demand are increasing, the price reaction apparently has not yet gone far enough to promote the anticipated business revival, and the prevailing situation, in the broader sense, remains one of diminishing consumption and production. This condition finds plain reflection in the decided halting of industrial activities, especially in the leading Eastern centres, and current reports of idle machinery and growing unemployment contrast sharply with the recent great manufacturing pressure and universal complaint of labor scarcity.

Atlantic Seaboard

BOSTON

Prices continue anything but firm. Only scattered sales, although movement all-rail shows notable increase. Tidewater situation about the worst ever known. Sellers have great difficulty placing coal. Hampton Roads dumpings for New England continue extremely light. Industrial activity slows down to marked degree. No inquiry for loading over New York piers. Trade interested in possible moves for next season. Shipping Board gives no sign of change in policy. Anthracite gets rapidly easier. All-rail receipts show increase. Lack of orders for broken, egg and pea. Middle houses actively solicit business. Retail demand very light.

Bituminous—The operating interests are laying siege to this market in their efforts to get orders for prompt shipment. Through Boston houses and by their own representatives quotations are being freely made all the way down to $2.40 for fair coals in the central Pennsylvania district. Indeed no buyer is left without the impression that any reasonable offer would be accepted for the sake of keeping certain mines in operation. All this activity results in little more than a feeling that the coal market is badly demoralized and that $1.25 @ 1.50 coal is a possibility for April and May. Certainly there will be no broad market by that time; there are opinions here that buying will not begin before July, so well stocked is this entire territory in every branch of industry and public service.

There have been some scattered sales the past fortnight, but for the most part salesmen are not able to get much response. Even small consumers whose storage is limited are cautious about buying, so little faith is there in present prices. Every buyer, large or small, is being hounded today to supply consignments, and no such thorough canvassing has been carried out in years as that now in progress throughout New England.

The tidewater situation could hardly be worse than it is at this writing. Extraordinary expedients are resorted to in order to place water-borne coal. There have been instances where cargoes have been consigned to a neutral point like Newport, R. I., "for orders," and there have been cases where cargo balances of 300 to 400 tons have been set out into the stream after the major portion of the cargo had been discharged and the barge allowed to wait until the balance could be placed. Shippers who have Emergency Fleet Corporation steamers under charter are at their wits end to know what to do with these bottoms the balance of the charter term. Eighteen steamers are now tied out in Boston Harbor awaiting business and the number will be augmented almost daily. Consignees who were counted upon to take monthly quotas to Apr. 1 are now confessing their utter inability to do so. All such calculations were based upon something like normal business, and no such condition as now prevails was foreseen.

Steam grades at the New York piers seem to be more and more a drug on the market. Inquiry is almost nil, and except for bunker use and for railroad fuel in railroad-owned barges, there is almost no coal being dumped. The relatively low rates on company barges to points east of Boston makes it an inducement for a limited tonnage to be moved in this way, rather than in steamers at the Shipping Board rate from Hampton Roads.

Under the conditions it is quite natural that the Hampton Roads shippers should take counsel together over the outlook for next season. Some conferences have been held, and as a result it is rumored there is some idea of selling on the basis of $3 f.o.b. mines for Pocahontas and New River. This means in excess of $5 f.o.b. loading port, a price level that today seems impossible to realize for coastwise business, so long as marine freights are unchanged. To try to maintain any such price the coming season looks much like inviting the same situation that followed a similar attempt in 1903, after the big strike. The price mark established that year in the spring was $3.35 f.o.b. Hampton Roads, only to drop by June 15 to $2.40 and $2.50. New England certainly cannot be relied upon to support an increased price program from the West Virginia fields, while Pennsylvania grades are so accessible and at a differential never so great in their favor.

Meanwhile the Shipping Board gives no sign of any change in policy as to coastwise freights; $3.25 continues the rate from Hampton Roads and $3.50 from Baltimore, leaving shippers to hold coal at the piers or at the mines and tie up the steamers they have under charter. More and more the much-talked-of export market fails to meet expectations and output in most of the Southern fields shows a steady decline.

Anthracite—Receipts of domestic sizes show further gains from week to week. The six days ended on Jan. 23 showed a daily average of 439 cars passing the New England gateways as compared with 330 cars for the first half of the month. Everything that looks like an order for broken, egg and pea is now being shipped, and many dealers who forgot to cancel their requisitions in season are now wincing at the proportion of these sizes they are called upon to accept. The fact is that more than a few retailers who went to the Fuel Administration for assistance got their full share of egg size through that channel.

The Philadelphia and New York city markets are of course limiting their current requirements to stove and chestnut, the only sizes that an increasing number of New England distributors are in position to take, and the result is a great effort on the part of all the shippers to move the less desirable sizes. A few cargoes are still coming forward either all egg, or with a large proportion of egg, and perhaps a single hatch of chestnut or pea, but another fortnight will probably see practically nothing coming forward but stove and chestnut, the majority of retailers are so loaded up with other sizes.

Boston and New York houses who normally represent "independent" operators are once more actively in the business and soliciting orders. By water current freights are to their disadvantage, but there is enough softening in prices, especially on egg, to put them on an even basis with the companies. All-rail they are still making sales in some volume.

NEW YORK

Demand for anthracite slow and trade is cancelling orders. Situation resolves itself into a "waiting game," and only several days of low temperatures will create a demand. Dealers look for concessions on Independent coals. Concessions made to move the anthracite steam sizes. Bituminous market quiet. Mines are working about half time and buying is slow. Bunker coals maintain full prices.

Anthracite—The trade is inactive, and instead of booking new orders dealers are receiving cancellations. This latter plan is affecting "independent" coals more than "company" coals, with the result that shippers of the former find it almost impossible to obtain the 75c. differential for their product.

The restrictions against stove and chestnut coals remain in force, but there appears to be plenty of these sizes to take care of all requirements.

Shippers of "independent" coals have about reached the point where they may have to suspend shipments from the mines, which will, of course, result in a slowing down of production. This action, it is understood, has already been taken by some small producers.

The outlook for better business here is not good. With spring not many weeks distant, neither dealer nor consumer is anxious to fill his bin with high priced coal when there is a possibility of the usual spring reduction. Reports from the coal fields are not so bright as they might be. There are occasional labor troubles, and the hope held out that as soon as they were discharged from their country's service the men would return to their former places in the mines has not come true altogether. Many of the men, according to information received here, are looking about for positions in other industries, many of them anxious for clerical places. The authorities, however, hope they may be able to induce most of the men to return to the mines for the winter, at least, in order to help the present labor situation.

Conditions along the line are much better than at Tidewater. "Independent" operators are able to dispose of most of their product to the inland trade, but are not always able to secure their full price.

Whatever may be said as to the lack of demand, the report of the Regional Director of Railroads shows that for the seven-day period ended Jan. 24 there were 6558 cars of anthracite dumped at the local docks. This was the largest week's dumpings reported since Sept. 27, when for the previous seven days 6727 cars were dumped. During the week ended Jan. 17 there were 4564 cars dumped.

The movement of the steam sizes may prove to be serious unless there is a decided increase in the demand for the domestic coals. These coals are almost a drug on the market, and operators are said to be stocking considerable. Quotations vary according to the grades. Buckwheat No. 1 was quoted as low as $3.15 at the mines, according to quality; rice from $2.25 to $2.50, and barley as low as $1 at the mines.

The retail trade has requested that the state fuel administration retain its supervision of the industry until Mar. 15 at least.

Current quotations, per gross ton, f.o.b. Tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$7.80	$8.55
Egg	7.70	8.45
Stove	7.95	8.70
Chestnut	8.05	8.80
Pea	6.55	7.30
Buck	5.10@6.05	5.90@6.25
Rice	4.65	5.10
Barley	4.15	4.30
Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The concessions from the Government maximum prices at which various grade of bituminous coal can be purchased here offer no incentive for buying. There is a heavy surplus of all grades at this market, and apparently the only qualities holding their prices are the best bunker coals.

Movement is slow and inducements fail to create any demand. Operators are not reckless, however, about cutting prices, realizing that the selling figure must be sufficient to cover the cost of mining. Some producers have found it necessary to slow up mining, and in various sections of central Pennsylvania and nearby districts many of the mines are working about half time. In the Fairmont region it was said that on one day last week nearly 400 openings were idle because of the lack of orders.

The trade fails to see any light ahead unless there is a cold spell of several days' duration. Many manufacturers who laid in large stocks of coal last summer and fall are said to be disposing of much of their surplus to other consumers not so fortunate, or are transferring the coal to other of their factories. It was also reported that some railroads are refusing further shipments because of oversupplies.

Various shippers see no encouragement in the immediate future. With the present stocks on hand some believe there will be no activity until about June 1.

Several of the local loading piers were affected by embargoes during the week just ended. Reports received here indicate a further slowing down in consumption due to the closing of many factories. During the week ended Jan. 24 there were 6103 cars of bituminous dumped at the local piers, as compared with 4110 cars during the previous week, an increase of 1993 cars.

Current quotations, based on Government prices at the mines, per net ton f.o.b. tidewater, at the lower ports, are as follows:

	Mine, Gross	F.o.b. N. Y., Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3 08	5.23
Prepared	3 36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher

PHILADELPHIA

Anthracite men becoming worried over outlook. Individuals finding it difficult to maintain prices and move production. Talk of restricting mining unless weather conditions change. Egg and pea draggy. Poor market for steam sizes, and prices being cut. No sale for barley or culm.

Anthracite—The market is rapidly approaching a critical stage. The shippers and the retail men both say something drastic must soon happen, unless there is a marked change in weather conditions. The retail men, especially, claim that nothing but severe and continual cold weather will keep equipment moving.

The trade appears surprised that the prices of the individuals have not broken. We have made repeated inquiries and cannot find that their 75c. differential has been cut into. They must be finding other markets for their product, especially on egg and pea sizes, for their trade is not only stocked with these two sizes, but it is not being moved. We do hear of their offering stove and chestnut for prompt shipment, if an equal proportion of egg and pea accompany the order. As last week, the suburban dealers appear busier than their competitors in the city proper, but even they say the end is in sight.

It must not be understood that the big companies are soliciting business, or are short of orders; that is, for prepared sizes. They are still shipping on orders entered as of Apr. 1, based on their 1916-17 business. They appear quite hopeful of conditions soon changing for the better, and before it is necessary for them to look for places to put their coal, at least before the end of the month. Naturally, their orders, with the lower prices, will be the last to be held. With a few exceptions, none of their salesmen are on the street, but next month, we have reason to believe, will see most of them looking over the ground. With the light demand for coal, the representative dealers are becoming quite apprehensive of how their numerous competitors will manage their business in the future. They claim it took a war to teach them how the business in the city should be conducted. Never before have the several hundred retailers located here worked in harmony. Price cutting and long-time credits have been entirely eliminated, and older and wiser heads are most anxious to maintain those high standards.

The dealers generally are not as yet informed of the new railroad ruling, prohibiting the loading of hopper coal cars of less than 75,000 lb. capacity. This will make quite a difference, especially to many small dealers located on Philadelphia & Reading tracks, whose yards are small, and who, before the present railroad administration, preferred the small Philadelphia & Reading cars, averaging 25 tons.

The individual operators are visibly worried over the outlook, and claim that while the present wage agreement with the miners is operative, they will lose money if they cut prices. We believe there is a movement on hand to restrict production by shutting down the collieries rather than equalize their rates with those of the big companies.

There is much speculation as to what the April price will be, and there are some in the trade who actually pretend to believe that the present company circular will be the basis of spring, with an increase of 10c. per ton for five months. The rumor, if such it may be called, has it that the individuals would adjust their prices to these figures. While we are much inclined to believe "the wish is father of the thought" with the small operators, we do know that they are seriously discussing this plan. Also do we know that they have never been satisfied with the increase in price of $1.05 per ton ordered by Dr. Garfield, on Nov. 1, 1918, to cover advance in miners' wages. They have all along claimed this was insufficient. On the other hand, it must be borne in mind that it is not new for the individual operators to want the big companies to advance their circular rates. The higher they are the better they like it. It places them in such a favorable position to undersell them, especially during dull periods, which, for years, has been the habit of some, and still receive a good price for their product. Just now, the "little fellows" are up a tree and are doing a lot of thinking.

There are no signs of steam trade improving. Buckwheat is away off, and has been offered at $3.10—perhaps 10c. lower. Some operators would be glad for offers of $2.40, for rice; barley and culm are practically out of the market; and it is said that no reasonable offer would be refused.

Bituminous—Operators report that a number of mines producing low-grade coal have closed down, and more are expected to follow suit. Prices for coal from these operations have been below those named by the Government. The majority of mines producing the higher grades are working, and it is proposed to close down rather than cut. Heavy tonnages consigned to piers lack boats in which to move the coal. This coal, in many instances, was sold at off prices, in order to release equipment, and now demurrage will accrue.

Numerous inquiries for export business are not being considered, because it is impossible to secure bottoms in which to ship.

BALTIMORE

More than enough coal to meet demands. Some consumers with big stocks of "war-coal" apparently dissatisfied now that better fuel is offering. Jobbers resuming old relations. Trade generally optimistic. Hard coal supply liberal in face of mild weather.

Bituminous—The situation here remains largely unchanged, for the trade has more soft coal than it can handle for the moment, despite the fact that numerous mines that usually supply this territory are closed or have shut down in part. There is practically no market here for less desirable fuels, even though many are offering at prices considerably off the fast-dying Government maximum. Some better coals are holding fairly well in price, but there is little real demand even for this class of fuel.

Some consumers in this territory, who during the war were most urgent to have purchasing agents secure fuel for storage over this winter, and who stocked up heavily on the kind of war-coal that was going to non-preferred industries, are now showing signs of dissatisfaction when better coals are offering at the prices paid for the inferior grades. The City of Baltimore, with some 40,000 tons on hand, is one of those making complaint, but the trade realizes that a mayoralty election is coming shortly and makes allowances.

With many mines anxiously seeking to get outlets for their fuels now that war contracts have come to an end, the jobbers here and elsewhere are in a position to get back into old lines of endeavor. The thing for the jobbers to do just now is to hustle around and find customers or to connect with old consuming interests.

Despite the present overstock of coal here, and the many cuts in prices, the trade as a whole is optimistic. With the dropping of Government regulation Feb. 1 it is believed it will only be necessary for business to clean up a bit on back stocks of poor coal before a healthy market at fair rates results.

Anthracite—Mild weather continues to cut down hard coal consumption here, and the supply of anthracite in this district is more than liberal. There can no longer be a doubt that many consumers will be able to get through the winter on the two-thirds delivered on orders early in the winter, unless February should be unusually cold.

Dealers here are already wondering whether there is to be a cut of even 30 to 50 cents in the spring. With prices as they now are, and with the threat of shortage of coal due to war work over, few handlers of coal here believe that the public will come in heavily in the spring for coal unless there is some inducement offered. Dealers say that there will not be any big stocking up by retailers on prospects in days when the mines require a cash trading. Not a few dealers see a big piling up of both wholesale and retail trading toward fall unless some attractive feature for early buying is worked out.

Lake Markets

PITTSBURGH

Market very quiet. Best grades nominally at Government limit. Steel industry's consumption decreasing.

There is practically no activity in the local coal market, and little progress has been made toward the development of prices that may be regarded as regular market rates. Producers of the best grades of coal regard the market as at the full Government limit and assert that they would not entertain bids at less. Lower grades could doubtless be bought at discounts, but there is no demand for them; indeed, there is little demand for any coal except high-grade gas coal, which appears to command the full price without difficulty.

Production of coal is confined almost entirely to the filling of contracts, and consumers as a rule find their contract shipments fully up to requirements, if not in excess. Negotiations against contracts for the new coal year will probably be taken up slowly, as neither buyers nor sellers have any definite idea as to what prices will eventually rule.

The steel industry, the biggest single consumer of Pittsburgh district coal, with the possible exception of the railroads, is running slacker and slacker each week. The mills are not only consuming less coal but are more indisposed to carry stocks. The winter, if it is a winter at all, is passing, and there is no prospect of great steel mill activity for months to come.

The market for the best grades of coal remains quotable nominally at Government limits, which are to come off at the end of January: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

TORONTO

Market continues quiet. Dealers well stocked with all grades. Industrial reconstruction proceeds slowly. Demand for bituminous light.

The coal market is quiet and dealers report but few orders. Owing to exceptionally mild weather, which has prevailed for some time, the domestic demand is light and mainly confined to the poorer class of consumers. The yards are well stocked with all grades and shipments from the mines are coming forward promptly. The readjustment of the industrial plants lately engaged in munition work to normal lines of production is slower than was anticipated, many alterations being deferred in the expectation of a drop in prices of material; consequently there is little movement of bituminous. Prices are as a rule well maintained, but occasional reductions have been made in order to effect sales.

BUFFALO

Too much coal. No relief in sight. Weather as mild as fall. Question as to the future of the bituminous trade. Will it break. Anthracite plenty also.

Bituminous—The reports of more coal than the consumer will buy continue. It now looks as if it would be a hard matter to hold the trade, though there are some who say the operators will shut down rather than allow prices to drop too low. At the same time the surplus appears to accumulate everywhere. It was supposed that the Montreal district was too far away from the source of supply to become overloaded as other districts were, but members agree that it is piled full of coal and will not buy any more freely than other sections.

There is nothing for the coal jobber to do but to pick up here and there the sale of a car or two and wait until the market comes back. It is agreed that there is surplus enough in consumers' hands to make any sort of activity impossible for a long time.

In view of the bituminous stagnation and the coming end of arbitrary prices the quotation must be made with caution, but still most of the coal sells at former prices or thereabouts, $4.65 for thin-vein Allegheny Valley, all sizes, $4.45 for Pittsburgh and No. 8 lump, $4.20 for sale mine-run or slack, $5.65 for smithing or smokeless, $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—Distributors of hard coal in the city are now sending out notices to customers who gave anxious orders last summer, but who are not saying anything about the coal now, asking them if they want it and adding that they are prepared to deliver the full amount. The two-thirds rule that was made then looks decidedly odd now. Not a single consumer goes near the Government fuel office now. Many of them will not ask for more than the partial delivery promised them last summer.

It is said that the city will not begin to use up its allotment, though the fuel administrator was making anxious trips to New York all through the fall, asking for more. It is mainly the weather that has created the conditions. With such weather last winter the situation would have been easy and no fuel office would have been easy. It has scarcely been down to freezing temperature in a fortnight.

CLEVELAND

Official lifting of all Government restrictions in this district is not expected to bring any startling market changes. Upper lake dock operators face a serious situation from the order that permits Illinois coal to come by rail into the Northwest cheaper than coal can be shipped off upper lake docks. Steam coal is slightly more in demand, while prices are somewhat firmer.

Bituminous—The local coal market just now presents a rather anomalous situation. Unemployment is more widespread and labor is offering itself at greatly reduced prices—both indicative of decreased operations and lessened coal consumption—while at the same time the mines are working better, more steam coal is moving into northern Ohio and talk of shading of Government maximums is much more repressed. One operator points to the fact that out of 2967 cars of standard No. 8 coal shipped from his mines last week only seven brought less than the Government price. Operators not well situated as regards contracts, however, are not spurning offers of 25 to 35c. below prices that prevailed prior to Nov. 11, while the supply of stripping and thin vein coal that is obtainable at a concession seems inexhaustible.

Attention of the bituminous world here now is centered on the lake situation. The Northwest, like the more southerly portions of the Middle West, has suffered—from the coal man's viewpoint—from extremely mild weather and the unexpected end of the war. Coal has moved off the upper lake docks in at a rate far under expectations. Not only that, but Illinois coal now can be shipped by rail into most of the Northwest cheaper than lake coal can be moved off the docks. Consequently, the opening of the 1919 lake season is likely to see 2,000,000 tons or more left on the docks, whereas 1918 and 1917 saw the docks pretty well cleaned up. In pre-war seasons a dock balance of 750,000 to 1,000,000 tons in the spring caused comment.

Retail demand for bituminous has remained stagnant, with weather conditions such as to demand a minimum use of coal for domestic heating. Massillon lump is now bringing $7.10, West Virginia splint $7.15, and No. 8 Pittsburgh $6.35. These prices are little changed from those of the past 60 days.

Anthracite—Receipts are heavy enough now to stisfy the light demand, and dealers continue to compete for business. Egg is selling for from $10.50 to $10.90, delivered.

Lake Trade—With the upper lake docks well stocked with coal and lower lake docks with piles of iron ore several million tons above the average, the 1919 lake season is not expected to be opened much before May 1. This, coupled with the fact that most of the larger lake carriers are holding grain cargoes at Buffalo—where the ice goes out two weeks or more later than at Cleveland and Toledo—is looked to cut the 1919 movement to as low as 25,000,000 tons. So far only one 1919 coal cargo has been floated, and it is unlikely that much lake coal will move toward the docks before the latter part of March.

DETROIT

Lack of buying demand both in the steam trade and among retail dealers, owing to large stocks in possession of each, creates a dull market for bituminous in Detroit.

Bituminous—With large stocks of bituminous still held by many of the industrial consumers and a large proportion of the retail dealers, jobbers and wholesalers find business light. Several causes have retarded cutting down the large supplies that were accumulated in accordance with admonitions of the Fuel Administration a few months ago, and which include a considerable quantity of coal of an inferior quality that was bought because nothing better was then available.

Cancellations of numerous contracts for products for war use having been made, manufacturing plants are now in a period of unsettledness, which is emphasized by the policy of the Government in holding back settlements on contracts and claims of the contractors. The diminished industrial activity curtails consumption of steam coal and tends to prolong the time during which the large reserve will be a check on new buying.

Continuance of temperature conditions unfavorable to stimulation of buying by domestic consumers is one of the reasons why retailers' stocks are still an impediment. Another reason is found in the poor quality of much of the coal and its unsuitableness for domestic heating plants of the type generally used in Detroit. The increased supply of coke, which many householders, accustomed to the use of anthracite, prefer to burn in place of bituminous, also holds back distribution of retailers' stocks.

The prospective ending of zone regulations on Feb. 1, is unlikely to cause much change in market conditions in Detroit, until the stocks now here are cleared away.

Anthracite—Owing to the mild weather consumption of anthracite has not been so large as in previous years. Shipments continue small in volume, but a moderate supply is in the hands of dealers. Low temperatures continuing for a few days would be likely to bring a rush of orders. The coke supply has done much to relieve the situation and help out anthracite users who were unable to obtain a sufficient supply of coal to meet their entire winter fuel needs. Few of the retailers are in position to buy anthracite freely because of their heavy stocks of bituminous.

COLUMBUS

The coal trade in Ohio remains quiet to the extreme. The weather conditions are still unfavorable for domestic demand. Large reserve stocks of steam grades are reported in all localities. The market is now purely a weather proposition.

The domestic trade remains quiet, as the thermometer is still ranging around the summer heat mark. Retail stocks are still large, and dealers are not in the market for any large tonnage. There is a fairly good demand for the fancy grades, such as Pocahontas and West Virginia splints. Retail prices continue firm at the levels which have prevailed for some time. Hocking grades are also selling to a small extent. Some cutting is reported, but not sufficient to cause any flurry in the trade.

Steam business is slow in every locality. This is due to the large reserve stocks on hand and also to the fact that business is rather slow in becoming adjusted to peace conditions. Michigan and northern Ohio are well stocked up, and the same is true of every locality to which Ohio-mined coal is shipped. It is believed that little steam business will develop before April, and producers are looking around to ascertain the prospects for the lake trade. Reports show that there is a large tonnage at the head of the lakes, and unless something happens to hasten consumption prospects for the coming lake season are not bright. There is some shading of prices for steam grades, especially mine-run, but the larger operators are not sharing in the price cutting and are generally holding up fairly well.

Production has not been good during the past week. In fact it is said that the output has reached the lowest ebb in years. Reports show that the output in the Hocking Valley field is about 35 per cent. of normal, and other fields are producing only a little more. Eastern Ohio, which has been favored by large steam contracts, is producing not more than 40 per cent. of normal. Little hope is expressed for an increase in production under existing conditions.

CINCINNATI

Remarkably mild weather continues, and demand is at a low level on account of limited consumption. Vigorous selling efforts are planned.

With a continuance of the same extraordinarily mild weather which has been experienced during nearly the entire winter, the hopes of the coal trade for a stimulation to business through more seasonable temperatures are gradually giving way to the conviction that there will be a heavy surplus of stored coal carried over after the winter has passed. It is of course possible that February and March will bring some severe weather, and force not only increased consumption of coal in the hands of consumers, but an additional demand for fuel; but as the season advances, with spring-like temperatures prevailing, and a corresponding lack of necessity for fuel, this possibility becomes increasingly vague as a definite factor in the situation.

The lack of a market for the present production of the mines, together with the certainty of large holdover stocks, furnishes the necessity for selling efforts during the coming months of an intensity hardly heretofore paralleled in the coal trade; and such efforts will accordingly be made, judging by plans which are being discussed by jobbers' and operators' representatives. The removal of the Government restrictions which have operated to limit distribution will of course make it possible to enter into efforts of this sort much more freely than was possible with those restrictions in effect, and members of the trade in this section will therefore go after the business which they formerly handled all through the Middle West and the North.

LOUISVILLE

General demand for all grades quiet, with no immediate signs of improvement. Operators busy lining up prospects for spring shipping to the lake region. Prices weak, but effort being made to hold steady.

There has been little demand for any grade of coal for the past few weeks, and conditions are not improving as weather conditions continue mild and consumption in a domestic way is far below normal. Steam consumers in many instances are reported to be carrying stocks sufficient to run them for weeks and months, while industrial demand is generally quiet.

Little river coal is coming in, and prospects for movement are not so good as they were, due to the market being stocked. However, some coal is expected in February and March. West Virginia is making a bid to get back in the market with the lifting of the zones, both by rail and water, principally rail.

The lifting of zone regulations is expected to improve conditions materially for a number of producers who have been shut off from their best customers for months past, and many expect to pick up where they left off.

Some price cutting is being done by mines which are long on production. Prices of 50c. and 75c. a ton under maximum Government prices have been quoted by long distance to local consumers of steam coal during the past week, these prices being for immediate delivery only, not on contract basis. Retailers are holding prices fairly well.

Eastern Kentucky and western Kentucky are both having trouble in marketing coal, western Kentucky probably having more trouble than eastern, except on some river business moving south, as there is very little demand for high grades and less for low grades.

Many mines are closed, and wagon mines and small mining companies are at a standstill. Labor is showing a surplus in many mining districts, and there is no shortage. Sidings are full of cars, although there is not much coal on cars waiting a market from the mines or at mines.

BIRMINGHAM

Conditions in steam trade easy, but requirements practically absorb the output. Domestic fuel short and market strong. Production making satisfactory gains.

There is an easy tone to the steam market here, and while there is a demand sufficient to practically take up the output of the mines, inquiries are not of an overinsistent character. The passing of Government control of prices, distribution, etc., is apparently causing little concern to either the producer or the consumer. There appears to be little likelihood of a lowering of prices as a whole, as the continuation of the present wage schedules will maintain a high cost. Such reductions and increases as will probably materialize with the return of the trade to normal conditions will be brought about by the adjustments based on quality. With a normal demand upon the district, which practically absorbs the output of the commercial mines, prices of the better grades of steam coals will more than likely advance, while no material reduction is looked for in the Big Seam and other cheaper grades.

Owing to the pronounced shortage of domestic coals in this district, which condition has existed since Apr. 1, 1918, there will more than likely be an advance by domestic producers. Dealers throughout the district and state are unable to get anything like the tonnage desired.

District Representative Holmes, of the Fuel Administration, has notified producers and jobbers that all requisitions made for coal and coke through any of the Fuel Administration agencies are cancelled, effective Jan. 31. Coal production for the week of Jan. 11 showed a gain of about 26 per cent. over the previous week, the output being 339,080 net tons.

Coke

CONNELLSVILLE

Coke market declining. Furnace coke becomes heater coke. Byproduct coke offered. Production increased.

The coke market lost no time in exhibiting decided signs of weakness upon the Fuel Administration's announcement that its price control would end with the month of January. At the beginning of last week fair grades of furnace coke were offered at $5.75, against the Government limit of $6, while indifferent grades found no sale at all to blast furnaces and had to be sold for heating purposes, bringing lower

and lower prices until by the end of the week $5 or less was the price.

While producers now attempt to explain that prices for "heater coke" have nothing to do with the regular coke market, blast furnaces point out that during the war equally poor coke was shipped to blast furnaces and invoiced at the full Government price, while furnaces were afraid to complain of quality for fear shipments would be shut off. There has been a limited demand for coke by blast furnaces, which as a rule do not bid over $5.50, and at this price they secure some coke of fair grade.

In foundry coke there has been an equal divergence on account of quality. Makers of the best brands still adhere to $7, the Government limit, but foundry coke of fair grade can be had at $6.50. The market is quotable at $5.50@5.75 for furnace coke and $6.50@7 for foundry coke, per net ton at ovens.

Producers of byproduct coke have been offering surplus lots to contiguous blast furnaces, and some sales have probably been made; but this coke does not get into the open market as it is always sold to nearby furnaces.

Nearly all the blast furnaces have contracts for coke, either for the half year or the whole year. Some of the contracts provide that in the event of the Government price control being taken off, the parties shall negiotiate to determine a fair settling basis week by week or month by month, while the others provide that "last Government price" shall rule. Several furnaces having such contracts have already notified coke operators that they desire to discuss this matter, evidently with a view to asking a price reduction. Their argument would be that otherwise they will have to go out of blast, and as the contracts are "requirement contracts," this would constitute quite an argument.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Jan. 18 at 291,332 tons, an increase of 19,966 tons, and shipments of raw coal at 195,693 tons, an increase of 24,778 tons.

Buffalo—The situation continues to ease off along with soft coal, and it is not now expected that any further shortage will occur for some time, if again this winter. The furnaces are getting most of their supply from the local byproduct ovens and prices range so as to compete with the Connellsville prices, which are $7 and $6 for the foundry and furnace grades. The freight here is $2.60 net. Fuel coke is as dull as bituminous coal. Dealers in it find that it does not compete closely with any coal and have to cut the prices to find a sale.

Middle Western

GENERAL REVIEW

News of removal of soft coal restrictions causes uncertainty. No market on any grade of coal.

The news of the lifting of all bituminous zone and price restrictions came as a surprise to the majority of the coal trade in the Middle West. It was generally known that restrictions were to be removed, but it was not expected that this would take place before Apr. 1, at least. These radical changes, which are to be effective on Feb. 1, have infused into the market an element of uncertainty and hesitancy which is anything but welcome at this time.

So far as the zone question itself is concerned, the effect of the new order is of far more importance to the retailer than to the manufacturer. Generally speaking, the retailer uses a substantial tonnage of Eastern coal, heretofore zoned out, while the manufacturer is only interested in short rate fuels, usually mined fairly near his plant. The average retailer in the Middle West is loaded to the guards with Mid-West coal. His trade, now that higher grade products from the East are available, will want better coal, and he will have to supply it. As a result, he will have to place orders for more coal, even if his bins are filled to overflowing with the Western product. It is a bad problem to be worked out, and it is going to be watched with interest. The operators will be as much affected as the dealers by the changes. Large tonnages of Illinois and Indiana coal replaced during the past year Eastern fuels. It will develop within the next few weeks whether or not Mid-West operators will be able to hold their ground against the inroads of Eastern coal. In the event that Eastern coal wins back its old position with the Mid-West trade, it will mean that another burden is added to the Illinois and Indiana operators.

The present market on all coals is hard to describe, chiefly because there is no market. Practically no purchases are being made, as all buyers are waiting to see what is going to happen, and by this waiting process it is believed they hope to break the market down to figures considerably below the coal prices, as set by the United States Fuel Administration. This is equally true of the railroads, as well as the general buying public. It may be said, in behalf of the manufacturer, however, that he has better grounds for keeping out of the market than the railroads have. In the first place, the manufacturer was loaded up to the maximum by the Fuel Administration, and in the second place, the end of the war made so many changes that he is justified in going easy for a while. The railroads, however, are about as busy as ever.

The question of railroad coal, by the way, is causing considerable comment unfavorable to the Railroad Administration. The opinion is that the railroads have no right to a price better than that given the general public. Furthermore, it is stated that the railroads are faced with the problem of reducing their operating expenses. There are, roughly speaking, two means by which they may accomplish this. The first, reduce wages; the second, purchase coal at a reduction. For many obvious and politic reasons, they will not reduce wages, as they do not want the responsibility of such a grave step. They have left to them, therefore, the remaining plan of buying their coal at a reduction. If they are able to do this, it will mean the operators will be forced to close their mines or reduce wages.

CHICAGO

Both steam and domestic demand practically dead. Plenty of anthracite coal to be had.

The weather in Chicago, and in fact the whole Middle West, has been very soft and springlike for the last week or ten days. As a result, much less coal is being burned than is normally consumed at this time of the year. The steam users are taking advantage of the present situation to reduce the large stocks they accumulated during the summer months at the order of the Fuel Administration, and consequently are not in the market at this time.

The domestic situation is practically dead at this writing. As soon as the news came that Eastern coal was to be allowed in this territory, the retail dealers naturally stopped buying Illinois and Indiana coal, in order to make room for Eastern coal, to be moved in after February 1. There has always been a certain demand for Eastern coal, and the retailer is reducing his stocks so that he will have a place to put his high-grade Eastern product.

It is stated that one company, operating mines in the Pocahontas district, and having a sales office in Chicago, received orders for 65 cars in less than two hours. This will give an idea as to what coal is being purchased now for domestic uses.

The anthracite situation is very easy. All restrictions, so far as the retail distribution is concerned, have been removed, and the householder may now obtain all the anthracite he wishes. According to information picked up from various dealers in and about Chicago, they are receiving all the hard coal they desire.

MILWAUKEE

Coal market one of the poorest on record. Decline in price of bituminous predicted. Hard coal unaffected by conditions. Movement of fuel slow all around.

The coal market at Milwaukee continues extremely dull, the season's business thus far being characterized as one of the poorest in the history of the trade. There is little demand locally, and the movement to the interior is simply nominal. Last year at this time hard coal was being dealt out gingerly in ton lots, and the problem of delivery was complicated by snow and ice. There were also restrictions on orders of soft coal. Up to the present time this season there have been only a few days of real cold weather, and the consumption of fuel has been abnormally light.

There is an overabundance of soft coal on the market, and a decline in prices of this character of coal is looked for by Fuel Administrator Fitzgerald about Feb. 1 because of the discontinuance of maximum prices at the mines and the elimination of the zone system of distribution. The maximum prices at the mines now range from $2.35 to $4.95 per ton.

Hard coal remains unaffected by the unseasonable conditions. Maximum prices on anthracite will remain in force. Customers are now being solicited and advertised for at the following prices: Egg, $12.20; stove, $12.40; pea, $11.05; buckwheat, $10.60. An added charge of 50c. per ton is made when coal is carried in.

Solvay coke is advertised at $11.50 and gas coke at $11. The coke schedule includes carrying-in charges.

The state and county fuel administration offices will be closed on Feb. 1.

ST. LOUIS

Mild weather continues to demoralize the market. No local or country call for steam or domestic. Steam sizes heavy. Trade much depressed and miners restless.

Continued mild weather has brought the market to an absolute standstill. This has even gone so far as to affect the Williamson and Franklin County fields. It is impossible to move steam sizes at almost any price, and the result is that mines all over the southern Illinois field are idle because they cannot dispose their screenings.

There is practically no country call for steam coal. This is a blessing in disguise, for steam coal could not be furnished on account of the surplus stock that the screening size would produce.

There is practically no domestic business excepting in small quantities, and retail firms with from ten to twenty delivery teams and trucks have use for about one. The supply of coal put in by the consumers last summer will in most instances last until the first of April.

This condition is prevalent all over this territory.

In the Standard field some mines work one day a week and some have been down for over a week. The miners in these districts are dissatisfied and figure that when they do work they will have to get more money in order to exist.

There is a small railroad tonnage going out, but nothing to speak of and the operators are fighting for this.

The question of getting a price that will pay for the cost of production seems to be somewhat vague, and there is no chance in the world for any kind of a contention on the part of the Government that these operators are in any kind of a combine to hold up prices. If they need any control at all it should be under the supervision of the Federal Trade Commission, which is generally supposed to advise corporations how to keep away from the bankruptcy courts.

In the Standard field the screenings are down to $1.25 for 2-in. lump, to $1.50; 6-in. lump from $1.75 up; mine-run at $1.55 to $1.65.

In the Mt. Olive field conditions are bad, but the operators are holding their prices with one or two exceptions. There is some railroad coal moving out of this field, and the greater tonnage of domestic moves north and west.

In the Williamson and Franklin County fields they are beginning to feel the effect of the mild winter for the first time. Several mines are idle on account of their failure to move screenings, and others have not enough lump and egg orders if they did want to work. The nut sizes are also slow in moving, some mines having to suspend work because they could not move the nut. The car supply everywhere is abundant and transportation shows some improvement, except on the Iron Mountain lines.

There is an effort being made by the larger operators in St. Louis to create selling agencies for all the mines on each line of railroad; for instance, all the mines on the Illinois Central, from Pickneyville to Belleville, will be handled by one company on a commission basis and another company would handle the sales from the Louisville & Nashville mines and another from the Baltimore & Ohio mines, etc. This would be an admirable plan if carried out without any malice, but the petty jealousies that exist in these fields prevent this from being carried out by local management. It can be successfully done if an outside, disinterested party were to take supervision of the work. The operators distrust their own leaders, and while that condition exists no hope can be held out for a just price on coal from the so-called Standard field.

About 100 cars of anthracite egg are now in transit to St. Louis, a few cars having arrived, and a few cars of West Virginia smokeless. Arkansas is practically out of the market on account of its high price. Coke is heavy with little call and nothing to be expected. Colder weather is the only thing that will save what is left. At the present time there are about 65,000 to 70,000 tons of storage coal in St. Louis held by the larger dealers. Anthracite egg is scheduled to retail at $12.35.

COAL AGE

Perpetuating the Thrift Habit

By Floyd W. Parsons

IT IS probably true that of all the serious problems confronting the American people today none is of greater moment than the question of how to encourage and continue the saving habit that has been developed in the United States during the war. The mine manager who believes that the matter of individual thrift on the part of his employees is no concern of his is perpetrating a serious folly.

One investigator found that in two great corporations the labor turnover amounted to 187 per cent., which when analyzed developed the significant fact that of this amount the proportion of married home owners was but 4 per cent., and that of married renters only 11 per cent. Nothing could prove more conclusively the benefits that accrue to a company from the development of thrift among its employees. It is unnecessary to stop to prove that permanency and stability on the part of employees breed efficiency and create profits.

When this country entered the war, we had in the United States only 300,000 investors. It is estimated that today 25,000,000 Americans are bondholders. This means that practically every family in the country, mostly through patriotic motives, has practiced thrift. Shall we view this change in habit with indifference and permit the Nation to slide back into the uneconomical customs that prevailed before the war? Or, shall we profit by the lesson we have learned and build in every community still greater organizations designed to perpetuate habits of economy?

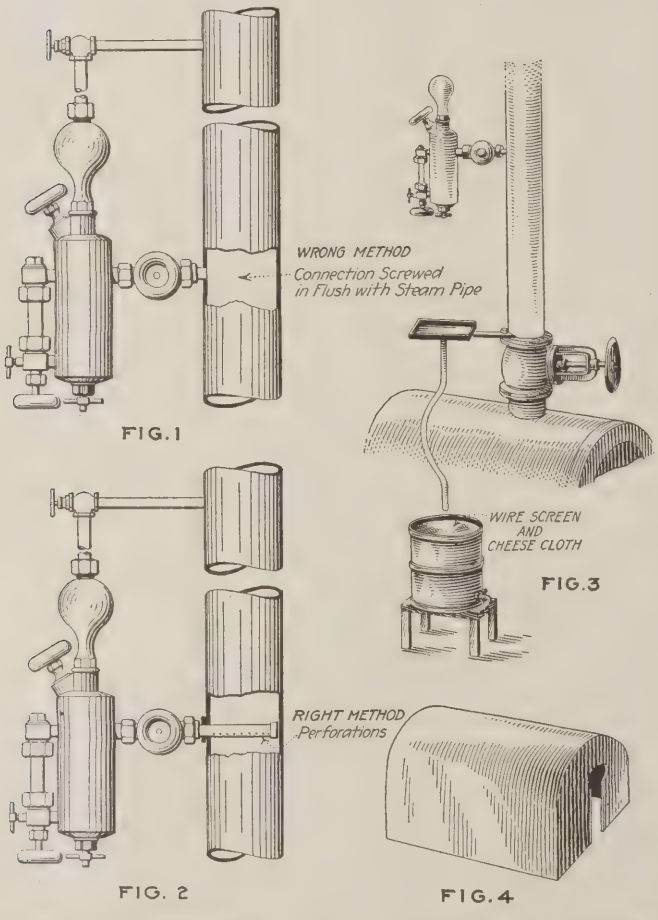
Throughout the world, restless dissatisfied people under the guise of Bolshevism, or some other "ism," are holding forth destructive ideas which they submit as a panacea for all political and social ills. Such campaigns fall flat when an effort is made to proselyte a community of property owners. The man who owns his home and who has invested his earnings in the bonds of his government, and in the stock of the company he serves, is not easily converted to a faith that teaches turmoil and destruction.

An extension among coal miners of the habit of saving would undoubtedly improve their living conditions; but it would do more, for such thrift would not only benefit the fuel industries but it would increase the volume of capital, thereby stabilizing the Nation's financial and political habits. It is for this reason that the great business leaders of the country are urging that employers should use such methods of distributing the forthcoming bonds of the Fifth Liberty Loan as can be continued permanently thereafter. In this way the thrift momentum will not be lost, and the habit of saving in America will be placed on an established basis.

The United States is splendidly equipped to maintain its present position as the most powerful nation on earth. Great Britain and Germany each has contracted an indebtedness of $40,000,000,000; France owes $30,000,000,000, while the indebtedness of the United States is only $21,000,000,000. Our position has changed from that of a borrowing country to that of an investing country—like England and France were before the war. Our people must be taught to understand the necessity of investing abroad, and that by so doing they protect themselves.

High wages can only be maintained by the workers putting back their earnings into money-making enterprises. Saving must be made as attractive and as easy as spending. Heretofore it has been a difficult and gloomy practice. We must put joy into it. It will be necessary also to introduce the business of saving to every individual. Last year the working people in this country bought $3,000,000,000 of Government securities, or nearly as much as the total average savings placed annually in all the savings banks in America. And this $3,000,000,000 was on top of the usual savings placed in those banks.

Right now is the opportune moment for each and every coal company to perform a real national service in fostering the habit of thrift among the miners of America. Incidentally, such action would be a marvelous stroke of good business.



IDEAS AND SUGGESTIONS

Attachment and Care of Lubricators to Insure Efficient Engine Operation

BY JACK L. BALL
Amsterdam, Ohio

For the smooth and economical operation of a steam engine or pump, a lubricator of some kind is needed to feed the oil in such manner that the cylinder walls and valves may be lubricated. As the sight feed or hydrostatic lubricator is the one most commonly used around the mines, I shall confine my notes to this type exclusively.

When connecting a hydrostatic lubricator to the steam line, the idea is, or should be, to so make the connection

FIGS. 1 TO 4. SUGGESTIONS FOR ATTACHMENT AND CARE OF LUBRICATORS

that the oil will mingle freely with the steam, insuring complete atomization and causing a better distribution of the oil to the valves and walls of the cylinder.

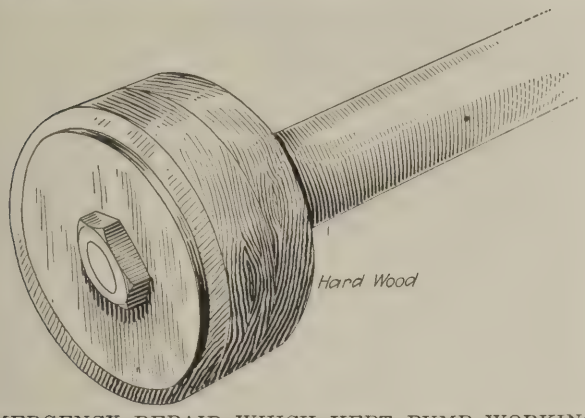
Fig. 1 shows a fault commonly met with. The connection is screwed in flush with the inside of the steam line, allowing the oil to run down and adhere to the side of the pipe. This method is wrong and uneconomical. The connection shown in Fig. 2 has been proved by experiment to be a much better method of attachment. It will be readily seen that with the latter connection the oil has a chance to mingle freely with the steam and is more completely atomized.

Lubricators should be cleaned quite often. This is easily done by blowing out with steam. A common difficulty encountered is that of the sight feed glass becoming dirty. This is caused by the oil not feeding in drops, but running out and sticking to the side of the glass, or arises from the drops being too large. If the drops are too large the permanent remedy is to make the feed nozzle smaller. If the oil feeds in a stream or the drops are too large, a temporary cure is to put a small piece of soap inside the sight feed glass.

It sometimes happens that a lubricator is in a place where it is exposed to cold. This, of course, congeals the oil so that it will not feed properly. A common way to remedy this is to wrap a piece of brattice or other cloth around the lubricator and the steam line. This will then keep the lubricator warm.

It is a common practice among engineers, firemen and pumpers when filling a lubricator to use a pair of combination pliers or a 10-in. pipe wrench to open or close the drain and filling plugs. This is wrong. These plugs are so made that they can be closed with a slight pressure of the fingers and be perfectly tight. They will remain so for years if this precaution is taken.

Probably few power-house men have taken the time or trouble to save the oil that is wasted from lubricators. This may be but a few drops a day or, again, it may be considerably more. At one mine where there are several lubricators used the device shown in Fig. 3 has been installed to save the waste oil. The engineers were much surprised to learn that enough cylinder oil was being wasted to lubricate, after proper filtration, a large steam-driven pump in the mine. Fig. 4 is a piece of roofing iron so formed that it will set in the tray shown in Fig. 3 and keep the lubricator warm in cold weather



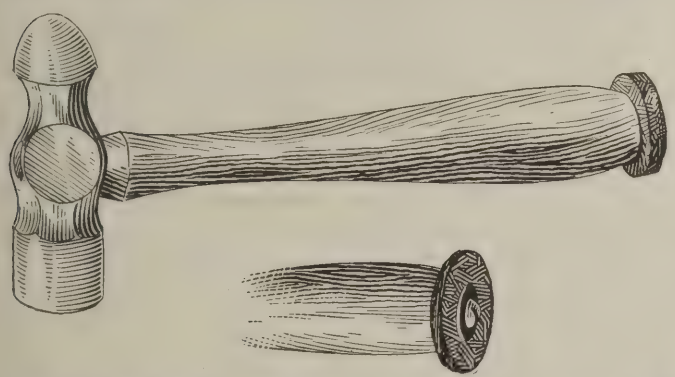
Novel Emergency Pump Repair Saved Both Time and Money

In coal mining, as in other phases of mineral production, output is an important factor in economical operation. When the output decreases the costs usually increase. Consequently, no reasonable diligence is spared in order to keep the mine product moving steadily. To accomplish this many expedients and makeshifts, usually of a temporary nature, are resorted to. Thus in one sense the most successful mine mechanic is the man who with small resources can temporarily accomplish the biggest results.

The accompanying illustration shows an emergency pump repair, or one that can be used in case of necessity. Should no packing be available for the regular pump piston, or should the piston head be broken, two or more pieces of hardwood plank may be drilled to fit

the bore of the piston rod and turned up around the circumference to fit the bore of the pump barrel. This fit should be a loose one, since all wood swells somewhat when it absorbs water.

To replace a regular pump piston head with two thin



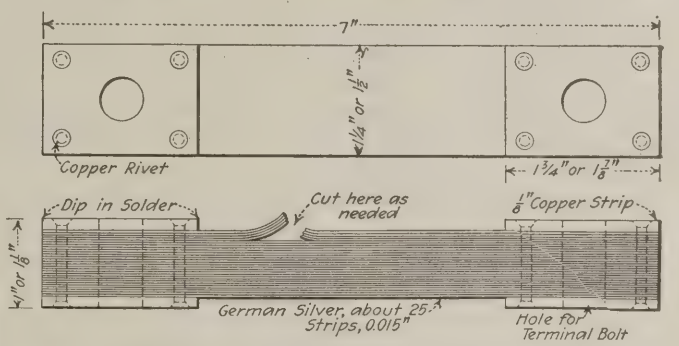
EMERGENCY REPAIR WHICH KEPT PUMP WORKING

follower plates and two circular pieces of plank can by no stretch of the imagination be considered as being a workmanlike job. In times of necessity, however, such makeshifts are entirely justifiable.

Preventing the Hammer from Slipping

Often a hammer will slip out of the hand of a workman who is engaged in repairing greasy machine parts. The accompanying photograph shows an accident of this kind, in which the flying hammer struck a coworkman,

HAMMER SLIPPED AND INJURED WORKMAN—THE GUARD SHOWN PREVENTS TOOL FROM SLIPPING



injuring him seriously. To prevent accidents of this character, hammers that are used when repairing oily machine parts should be provided with a leather washer fastened to the hammer handle as shown in the drawing.

Generator Cable Resistance That Will Last Long Time If Properly Installed

By J. J. Nolan
Linton, Ind.

The accompanying illustration shows resistance that has been in use in two separate power plants where two or more direct-current generators are operated in parallel. Quite often little attention is paid to the load when it is not equalized between two or more generators working in parallel, and it is a common occurrence to see one generator taking more than its share of the load unless the attendant keeps moving the rheostat throughout the day. Around coal-mining plants the load is highly variable and when switches are pulled after closing down at the end of the day's run a difference of 10 to 25 volts might be found on the voltmeters of different generators.

On looking closely several pounds of german silver might possibly be found connected across the extreme ends of the series field of the generator that is inclined to take more than its share of the load. This is an old practice, but seldom has it been found to do any good. The cables leading from the machines to the board

RESISTANCE FOR GENERATOR CABLE

should be of the same cross-section and length if the generators are of the same capacity. If cables leading from one generator are longer than those from the other, a suitable resistance should be connected into one of the shorter cables. This resistance should be of suitable strength and of such nature that the rise in temperature necessarily resulting from its use will not carry into the terminals of the cable or to the stud where it is connecting and injure the connection, melt the solder or pit the joint, later offering too much resistance at times and perhaps causing an "open" in the line or a serious burnout on heavy load that would result in a shutdown.

The resistance here illustrated will last indefinitely if installed properly with a clean snug joint, bolted up firmly. The ammeters should be watched carefully when a fair load is on, and if the generator which formerly took the largest share of the load continues to do so, one or two strips should be cut and results noted. Also, the resistance piece should be felt during the load so as to determine if it is offering enough resistance; if not, more strips should be cut and bent back until the desired results are obtained.

The man who does not get a certain satisfaction out of his work is losing the best part of his pay.

Safety Gate Protection at Mine Shaft

By R. P. HINES
Fairmont, W. Va.

SYNOPSIS — *A combination of devices is here described that will permit the shaft gates to be opened only when the proper cage is in place at the landing. The cage then can not be lowered until the shaft gate is again closed and locked. A few special pieces were required, but most of the material used was of standard design.*

IT IS the purpose of this article to describe the method used by a large operating company to obtain protection for the gate at the man, or surface, landing of one of its mining properties in the Pennsylvania bituminous district. In order, however, that the exact relation of the protective system and devices to the other parts of the equipment may be more fully understood, a general description of the hoisting system will first be necessary.

The mining plant includes a double-compartment shaft, the two compartments being of 6 ft. 10 in. by 11 ft., and 7 x 11 ft. on 7 ft. 4 in. centers. Through these the coal is hoisted from a depth of 345 ft. by an electrically driven hoist, also used for hoisting and lowering men.

The hoist is a double, conical, grooved-drum machine, each drum being 6 ft. 6 in. diameter at the small end and 8 ft. 6 in. in diameter at the large end, and of sufficient face to coil 500 ft. of 1¼-in. wire rope, allowing three extra turns for fastening. One of the drums is tight on the shaft, the other being loose and driven by a heavy toothed internal clutch wheel with machined teeth, for taking up slack and for the adjustment of the length of rope should it be desired at some future time to hoist coal from a lower level. Two band brakes are provided, these being of the weighted type, operated by air cylinders.

The hoist is operated with the cages and cars in balance, self-dumping cages being used. It is driven by a 250-hp. three-phase, 60-cycle, 450-r.p.m. synchronous-speed, 2200-volt, variable speed, slip-ring induction motor. This is attached to the pinion shaft by a flexible coupling, single reduction herringbone gearing being used.

A master-type drum controller is mounted on the hoist operator's platform, being used in connection with a 2200-volt, air-break, two-pole reversing contactor for reversing the direction of rotation of the hoist motor, and also a low-voltage contactor equipment for varying the speed of the motor, by varying the resistance in the rotor circuit.

A bank of three 85-kva., single-phase, 60-cycle, outdoor type, oil-insulated, self-cooled transformers are mounted on a steel framework outside the hoisthouse. These reduce the voltage from 11,000, at which the power is received from the transmission line, to 2200 volts, at which it is delivered to the hoist motor.

The electrical equipment furnished included the usual standard type of limit switches to be installed on the guides to prevent overtravel of the cage. There was also included a motor-driven air compressor to furnish compressed air for the operation of the brakes of the hoist.

There was later added to this equipment a device for the prevention of overwinding and overspeeding, including special man-landing protection. The electrical control devices are so arranged that when hoisting men it is impossible to run the hoist in excess of 900 ft. per minute, rope speed.

This device for the prevention of overwinding and overspeeding is of Vulcan Iron Works manufacture, and together with the scheme for automatically stopping the hoist at the man landing is protected by letters patent.

Fig. 1 accompanying this article gives a good idea of the device, as it shows it with the cover removed. A horizontal shaft, or spindle, bearing a square thread is carried in bearings at each end of the box-like supporting structure. One end of this spindle carries a

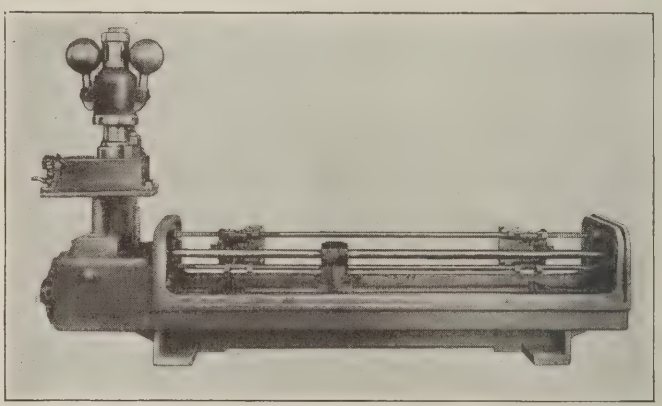


FIG. 1. VULCAN IRON WORKS FLYBALL GOVERNOR OVERSPEED DEVICE, COVER REMOVED

sprocket wheel, which is chain-driven from another sprocket rigidly fastened to the mainshaft of the hoist. This main horizontal spindle is also arranged to drive by means of bevel gears, the vertical spindle carrying the flyball governor.

The threaded spindle works through a rider, sliding over a round rod, as indicated, and this rider moves backward or forward, depending upon the direction of rotation of the hoist. Two sets of controlling contactor fingers are provided, and these are adjustable in their position and are actuated by the rider. Two of these contactor devices are used for protection in the normal operation of hoisting coal and are set so that the rider will travel from one to the other while the cage is traveling from the bottom of the shaft to the dump.

The other pair of contactor devices are for landing protection, and are set so that the rider will make contact with one of them as each cage reaches the man, or surface, landing. These contactor devices are wired in the circuit, so that when they are actuated by the rider in its travel they will open the control circuit of the hoist motor and equipment, which automatically shuts power off the motor by tripping the main oil circuit breaker and also applies the air brake.

The flyball governor, which is driven at a speed proportional to that of the hoist, is arranged to open a contactor wired in the control circuit and shut off power and apply the air brake, should the speed of the hoist reach 10 per cent. above the normal operating speed. A retardation feature is also provided and operated from the flyball governor, which accomplishes

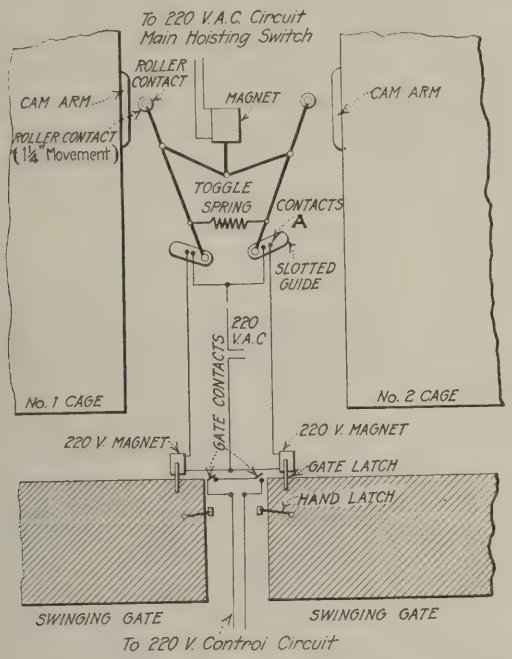

FIG. 2. AUXILIARY DEVICES AND SCHEME OF CONNECTIONS

an automatic slowing down of the hoist as the cage approaches the dump by opening, successively, the contactors controlling the amount of resistance in the rotor circuit of the motor, thus gradually and automatically inserting this resistance and slowing the motor down.

This motor resistance is arranged so that the cage must approach the dumping horns at approximate speeds not greater than 1200 ft. per minute at a distance of 25 ft. below the dumping point, 900 ft. per minute at a distance 20 ft. below the dumping point, 600 ft. per minute at a distance 15 ft. below the dumping point and 300 ft. per minute at a distance 10 ft. below the dumping horns. This requires that the hoisting engineer must apply his brake properly each time a hoist is made. If this is not done, all contactors and the main oil circuit breaker are opened, cutting power off the motor and applying the air brake.

In first considering this problem of safety gate protection it was thought that a mechanically or electrically operated device to actually open and close the gates would be required. Accordingly, such an equipment was designed and drawn up. It consisted of steel gates provided with rollers at the bottom running in steel guides, the gates having a rack attached to them, through which they were to be opened or closed by an electric motor having a pinion on its shaft in mesh with the rack on the gate. By means of an automatic contactor control system for the motors, these gates were arranged to automatically open when the cage stopped at the man landing and to remain open as long as the cage remained there, and to close automatically just as soon as the cage left the man landing, either going up or going down.

The contact-making device controlling all this automatic operation was to be supported from the guides and to be engaged by a wheel on the cage. It was designed so that in the normal operation of hoisting coal there would be no engagement between the contact-making device and the wheel on the cage, this only being effected when the man-landing switch of the control system was closed, which had to be done before men could be hoisted. The gate-operating motor was to be equipped with a solenoid brake arranged to be applied fully to hold the gate at the end of its travel in each direction, either completely open or tightly closed.

Estimates covering the cost of this proposed scheme showed that it would be comparatively expensive and require a considerable time for its production, so the whole scheme of a mechanically or electrically actuated gate was held in abeyance and the problem approached from another angle.

Reference to the safety requirements as outlined by Art. 8 of the Pennsylvania Bituminous Mine Law was had in order to obtain all the detailed information possible. This article of the law reads as follows: "All shafts shall be provided with safety gates controlled by the cage at the top and intermediate landings, and said gates to be approved by the inspector."

In analyzing the basic intent of this law it seemed clear that safety was the fundamental requirement and that there was no intent in the law to circumscribe or prescribe the specific means by which the safety features were to be secured or to require certain methods of securing this, to the exclusion of all others. Consequently, it was believed that there was no sound rea-

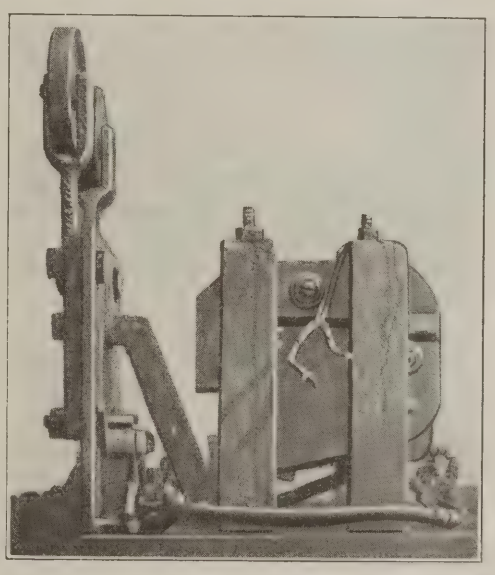

FIG. 3. TOGGLE, TOGGLE MAGNET AND ROLLER CONTACT ARMS

son for interpreting the law to be satisfactorily complied with only by gates mechanically or electrically opened or closed. Therefore, in seeking the second solution, there was eliminated entirely the proposition of any mechanical or electrical devices for actually opening or closing the gate.

It was thought that the complete protection that the law sought to obtain would be provided by fulfilling the

two following conditions: (1) The shaft gates must be at all times locked in the closed position, except when men are being hoisted, and then only when the cage is directly opposite the man landing. (2) In the event that the shaft gate is left open for any reason the hoist will be rendered inoperative, and it will not be possible to move the cage an appreciable distance either up or down.

Believing that if the two basic requirements as above stated were met the safety standard would be complied with in every possible way, some solution was sought which should completely satisfy these conditions.

Having in mind the excellent protective features provided by the flyball governor overwind device, for all contingencies and emergencies which might occur in the normal operation of the equipment in hoisting coal, and in man-landing protection, it seemed but natural to the man to whom this problem was presented at this time that this device operating in conjunction with some specially designed auxiliary parts might be made to meet also the additional requirements of complete safety gate protection.

This proved to be the case, but in order to get a clearer idea of the way in which the normal operation of the device was modified by the auxiliary devices designed, the operation in the normal hoisting of men will be outlined. This is as follows:

In the operation of hoisting men, the bottom cager gives the usual man-hoisting signal, in this case three bells. The hoist operator then closes a single-pole, 220-volt switch on the operating platform. This switch places the man-landing features of the overwind device in operation, and at the same time energizes a signal light at the top of the shaft or surface landing and a signal light on the hoist dial; also a signal light at the bottom landing of the shaft. Upon noting the light, the bottom man signals the hoist operator to start, knowing from the signal light that the man-landing features of the overwind device have been placed in operation. If for any reason the hoisting engineer should fail to shut off the power and apply the brakes just as soon as the cage passes the man landing, the power is automatically cut off and the air brake applied, thus bringing the cage to an absolute stop before it reaches the dumping position.

In the actual mechanisms applied to the overwind device no originality is claimed, as they are in daily service on some types of automatic push-button control elevators; but the feature of selective operation, whereby the safety gate at the man landing can only be opened when hoisting men, and then only when the cage is directly opposite the landing, is possibly new in its connection with and application to the type of overwind device on this hoist.

Referring to Fig. 2, which shows the auxiliary devices and the scheme of connections, a roller contact device is attached to each of the two cages. A collapsible toggle, having two arms, is attached to an "eye" beam between the two shafts, this toggle being operated by a 220-volt magnet, as indicated. It is located so that when the magnet is energized the two arms are thrown out into such a position that each may be engaged by the roller contact device on the cage in that shaft over which the arm projects. Each gate at the man landing is held closed by a bolt, which is arranged to be raised by a magnet whose winding is energized from the 220-volt control circuit, and is wired in series with the contacts which are opened and closed by the toggle arms. In the normal operation of hoisting coal the toggle magnet is not energized and the toggle collapses, the roller contacts on the cage not engaging the toggle arms.

When men are to be hoisted the hoisting engineer, by closing the single-pole switch which places the man-landing overwind in operation and lights the signal lamps, also energizes the 220-volt toggle-operating magnet, which throws the toggle arms out into position where they may be engaged by the roller-contact device on the cage. When the cage comes exactly opposite the man landing, the roller contact on the cage engages the toggle arm and causes this to close the circuit to

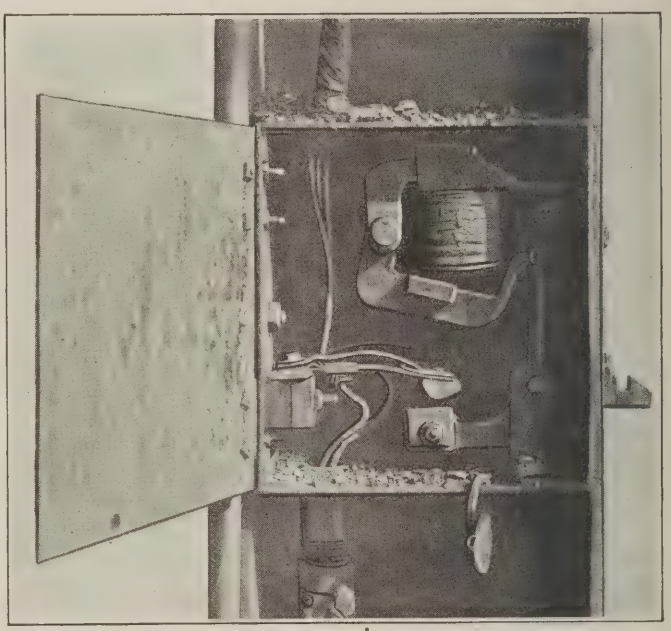

FIG. 4. MAGNET WITH GATE BOLT, GATE LATCH AND INCLOSING BOX

the gate bolt magnets, and lifts the gate bolt, which permits the gate to be opened. The control circuit of the hoist is wired in series with the contacts which are closed by the gate hand latch. As soon as the hand latch is released and the gate opened, the control circuit is broken, all contacts opened, and therefore the air brake automatically applied to hold the hoist fast with the cage at the man landing. As long as the control circuit is open, the hoist is inoperative and cannot be moved.

In order to prevent the operator from opening the single-pole switch placing the man-landing protection in operation, before the cage has reached the landing, this switch has been arranged so that it cannot be opened unless the air brake is applied. This is accomplished by a magnet which holds the switch fast after it is once closed, the windings of this magnet being energized when the switch is closed. The air brake of the hoist is provided with a contact actuated by the piston, so that when the piston falls, which it does when the air brake is applied, it opens the 220-volt circuit of the magnet holding the double-pole switch closed, and this switch may then be opened.

While the opening of the single-pole man-landing switch would not in any way affect the safety gate protection, inasmuch as the gate could not be opened until such time as the switch was thrown in again, it does affect the safety protection as installed by the hoist builders for hoisting men, and this additional protective feature was incorporated to comply with the wishes of the mine inspector.

In the application of these auxiliary devices the mechanical details were made at the shops of the mine. The magnets and cores for the toggle operation were such as are standard in the equipment of mine-hoist motor contactors, while the magnets and cores used for the gate bolt-lifting mechanism are standard as used on the control boards of push-button-operated elevators.

The fact that the brakes of the hoist are air-actuated and that all operations are dependent on one 220-volt control circuit, taken in conjunction with the application of the type of flyball governor overwind device, has made more easily possible the accomplishment of the complete and comprehensive safety features provided.

It is considered that every safety requirement has been fulfilled, and this with a minimum of operating parts and resulting complications. It may be further pointed out that if from any cause outside normal operations the 220-volt control circuit is broken, that the power to the hoist motor is automatically cut off and the air brakes applied.

The fact that the gates have to be manually operated is thought to be an additional safety feature. With a mechanically or electrically lifting gate, there is always the possibility of the gate striking a person, with resulting injury. With a mechanically or electrically operated swinging gate there is the possibility of sweeping a person into the shaft. With the manually operated gate there is no possibility of injury as the hoist is inoperative until the gate is closed and the control circuit completed.

The flyball governor overwind device had been operating satisfactorily for more than a year previous to the application to it of the safety gate protective features, about ten months ago. Since that time both have been operating together with perfectly satisfactory results.

It is hoped that this article may be of benefit to others having a similar problem to solve; also that it will prove of general interest to many operators of electrically driven hoists.

Combustion of coal is not a simple oxidation of carbon and hydrogen to CO_2 and H_2O, but is a complex process. The volatile matter from heated coal contains tar, saturated and unsaturated hydrocarbons, carbon monoxide and hydrogen, all of which must be burned in the space above the fuel bed. These materials all react among themselves and with the products of their combustion. Each reaction exerts its influence upon the others and can not be considered separately. The high temperature in the furnace favors the formation of simpler compounds so that the final products to be burned are largely soot, CO and H.—*Bureau of Mines Bulletin No. 135.*

Important Development of Large Coal Tract in Greene County, Pennsylvania

The development of a 7600-acre tract of coal land in Greene County, Pennsylvania, by the Buckeye Coal Co., has reached such a point that shipments of coal are about to take place. The Buckeye company is a subsidiary of the Youngstown Sheet and Tube Co., and the coal plant at Nemacolin, Penn., will supply coal to the byproduct plant of the parent company at Youngstown, Ohio. It is expected to make the Buckeye operation a model plant with a capacity of 6000 tons of coal daily, giving employment to some 1500 men. The Buckeye mine is said to be the first development on a large scale in Greene County, and likely the mine will not reach full capacity for several years. Shipments will be made at present by water or until the completion of a railroad spur from Crucible, eight miles distant.

The main openings to the coal at this plant are shafts about 250 ft. deep and lined throughout with concrete; a unique feature of the airshaft is its circular section —being 20 ft. in diameter. The main or hoist is elliptical in cross-section. Considering the large daily tonnage desired, it was decided to hoist the coal in skips instead of by cages; this is in line with recent developments made at some mines which are expected to become record producers.

The air shaft is completed and a fan has been installed with a capacity of 400,000 cu.ft. per minute. Other mine openings at this plant include a man and material slope 857 ft. long driven on a 19 deg. pitch and concreted from the surface to the coal. Until the completion of the main shaft and tipple, the product of the mine is hoisted through this slope and onto a temporary tipple—six cars per trip. A shop equipped to handle all ordinary mine work and repairs has been erected and equipped.

Especial attention has been paid to the housing problem at Nemacolin. Houses for the superintendent, chief engineer, store manager and doctor have been completed. There have also been built 120 houses for the workmen; of these 80 are five-room dwellings and 29 are six-room houses. To add to the comfort of the employees, 76 of the houses have been equipped with hot air furnaces; 35 houses have bathtubs while the remainder have showers. Every house has a toilet and electric lights. Some 400 acres have been reserved for a town site on a knoll overlooking the Monongahela River; the town covers about 50 acres.

The sanitary condition of the Nemacolin community has been provided for in a sewage disposal plant which has been constructed with the approval of the State Board of Health. Both Protestant and Catholic churches will be built, and plans have been completed for a six-room school building with provision made for additions. The streets of the town will be named after the leading generals of the recent war. The main thoroughfare will be known as Pershing Boulevard; other streets and avenues will be named Foch, Haig, Petain, Diaz, Bliss, Wood and Joffre respectively. The local officials of the Buckeye Coal Co. are C. M. Lingle, general manager; W. H. Gages (formerly mine foreman of the Frick company at Connellsville), superintendent; A. W. Hesse, chief mining engineer, and G. F. Bell, chief clerk.

Mudding Coal at St. Eloy, France*

SYNOPSIS — *The French feed mud into the crevices of the coal in heated ribs so as to extinguish the fire in them. This mud may be fed in from the surface or forced in from below, a tank being preferably used as the immediate means of delivery. Apparently the operation of the tank by compressed air has been found greatly preferable to the use of such water pressures as are apt to be available. Moreover, water operation is wasteful of water and slower than air pressure.*

THE flushing method is the most efficacious means for the fighting of mine fires. It was already practiced at Commentry[1] before 1878, and H. Fayol, in his study of the fires of that mine in the *Industrie Minérale,* 1889, shows the excellent results obtained by that process. The material was delivered not only from the surface but also from the mine, the flushing material being placed in the latter instance by diaphragm pumps which forced the material to be flushed into a borehole that sloped upward in the coal.

This process, which will be termed the "process from below," is still practiced in many mines, the muddy liquids being forced into the coal by pumps, as at Monteau-les-Mines, where disk and ball pumps are still used.

In the application of the process from below, an innovation was introduced at the mines of Aubin, in 1910, by M. Clavelly. This consisted in the use of a flushing tank which was described in the *Bulletin* of September, 1912. It was an iron tank, or barrel, connected at one side with a water line under pressure and having, at the other side, a valve through which the flushing material was ejected.

The flushing materials were introduced in the tank by an opening fitted with a self-closing device. They were carried off, of course, by the flow of water, the liquid being agitated from the outside so as to mix the material with the water, thus permitting it to be flushed into the borehole.

At St. Eloy, flushing from below has been practiced since September, 1915. At first a flushing tank identical with the one used at Commentry was used to deliver flue ashes, but a great quantity of ashes was quickly used up and the available stock at St. Eloy and in the neighborhood soon ran out.

For this reason, the management proposed the use of washery waste with 50 per cent. of ashes, the former being valueless material of which there was practically an inexhaustible stock. But this waste is much heavier than flue ashes, and using the same velocity of ejection half the material was left at the bottom of the tank. To make it possible to use these wastes, it was necessary to increase the speed of evacuation; and for this purpose the pressure of a compressed-air line was utilized to force the mixture into the boreholes.

The flush tank is operated by air pressure and is similar to that used at other mines, notably at the mine of the Companie de Béthune, where it was resorted to for strengthening the concrete lining of the heading by an application of cement grout.

It is an iron barrel (Fig. 1) into which is introduced the material to be injected and the water needed for the injection. It is fitted at its lower end with the outlet pipe *V*. This pipe is connected with the borehole, and at the top near one end is the tube *A*, connected with the compressed-air line. After the tank has been closed, the mixture is kept in agitation by a stirring device, operated by a handle from the outside. As soon as the material is well mixed compressed air is let in, and it forces the mixture into the borehole. As soon as the tank is empty, new materials are introduced, and the machine is again ready for operation. The water could be fed into the barrel by the opening by which the flushing material is introduced, but it is more convenient to connect with the water line through the pipe *E*.

Self-Closing Valve Saves Time

In order to avoid waste of time at each operation, the opening for the introduction of the material is fitted with a self-closing valve, which can be operated rapidly by a lever placed outside the tank. A second pipe *A'*, similar to the pipe *A*, is placed at the top of the tank. Through this the pressure of air is released before the tank is refilled.

The self-closing plug *R* is provided for cleaning purposes. The capacity of the tank is 119 gal. It is mounted on a truck, and the whole apparatus weighs 1610 lb., the tank weighing 1221 lb. and the truck 388 lb. The mines at St. Eloy have now three flushing machines of this type.

The rapidity with which the material is flushed depends on the effective pressure of the water or of the air with which the tank is supplied. When compressed air is not used, the effective pressure at the flush tank is much lower than the static pressure of the pipe lines, on account of the large loss of head in the pipes. A head of 197 ft. was used, but the pipe line was about 1312 ft. long, and the pipe had an inside diameter of only 1.29 in.; moreover, it had many elbows. The speed of the water reaching the empty tank was only about 3.28 ft. per second, corresponding to a theoretical effective pressure of 2.15 in. of water.

When the flushing tank is filled up and is delivering a flow in the borehole, the speed is still lower because of the resistance of the coal to the passage of the fluid. Thus slowed down, the speed of the current is not sufficient to carry along the heavy elements in the flushing material.

The use of compressed air at a pressure of 56.9 lb. per sq.in. gave the material a theoretical speed of 82 ft. per second, assuming a specific gravity of the fluid mass such as to reduce the value of the head from 131

*Abstract of Chapter I of an article by M. A. Plassard, assistant manager of the West Canadian Collieries Co., Ltd., published in the Bulletin de la Société de l'Industrie Minérale. St. Eloy is about in the geographical center of France in the Department of Puy de Dome. A small basin of coal takes its name from St. Eloy.

[1]Commentry is located near St. Eloy, but in another coal basin.

ft. to 104.6. In fact, because of the resistance of the borehole, and because of the presence of a small quantity of air in the water, and of various corrections to be made to the theoretical formula, $v = 2gh$, the theoretical speed is not as significant as it at first seems. The actual speed is more readily determined by an observation of the time needed to empty the flushing tank; 119 gal. flows out through an orifice of 1.31 sq.in. in about 30 seconds, when the resistance to mudding is at a minimum.

When the resistance of the cracks increases, the speed of evacuation decreases; but it is nevertheless sufficient to carry away all the breaker refuse so long as mudding is continued. The same result would obviously be obtained with the flushing tank if water pressure only were used; provided that sufficient effective pressure were available. Lacking such free head, a pump can be connected with the intake line, and it will provide the required pressure.

The air acts on the fluid mass like a piston and does not modify the proportion of water. In using the flushing machine with water pressure, or rather with a water current, the water continually thins the initial mixture, the operation being stopped when the mixture is sufficiently thin. This necessitates using an inflow of water equal to at least twice the capacity of the flushing tank.

Even if the pressure obtained with water is readily made equal to the air pressure, the difference in operation would still give the air pressure an advantage as regards consumption of water and speed of operation. The speed of evacuation when compressed-air is used being amply sufficient to carry away the material without leaving any residues in the tank, the outlet pipe has been placed at the lowest point in the tank. So disposed, it is possible to utilize the full capacity of the flushing machine.

It is obvious that elements that are too bulky cannot be profitably introduced into the flushing tank. Such materials are frequently found in flue ashes. They comprise clinkers, broken bricks and clay lumps, the last of which break up but little when thrown into water. Large quantities of coarse material are found also in the basins, where the waste from washeries is drained away; so the washery waste does not flush without residue unless screened.

To clear the flushing material of those undesirable elements, it is passed over a screen pitching at an angle of 45 deg. with 0.78-in. (20-mm.) round holes. The flushing tank can be operated by two men, or even by a man with the help of a boy. When the flush tank is empty, the water inlet is opened, and the material is introduced by shoveling it into a removable funnel. The assistant aids the material to slide into the tank. The loading being done, the attendant waits until the water has completely filled the tank, when the water inlet is shut.

The agitator is then turned a little, to render the mixture homogeneous, the air inlet being opened meanwhile. The lowering of the slush in the tank is soon evidenced by the fact that the pallets of the agitator turn with greater ease.

As soon as the tank is empty the compressed-air inlet is shut and the air outlet opened. In this way no compressed air is forced into the coal which is being mudded. In fact, the discharge of air in place of water and mud into the heated mass would, if it occurred, be one of the objections to using compressed air for fire mudding. But the process described above makes it unnecessary to discharge any important quantity of air into the borehole. All that does enter passes in with the water and is the outcome of the agitation of the mixture during the discharge of mud.

However, the discharge of air into the borehole would seldom do any great amount of harm. The coal to be flushed may be classified as follows: (1) Coal in a

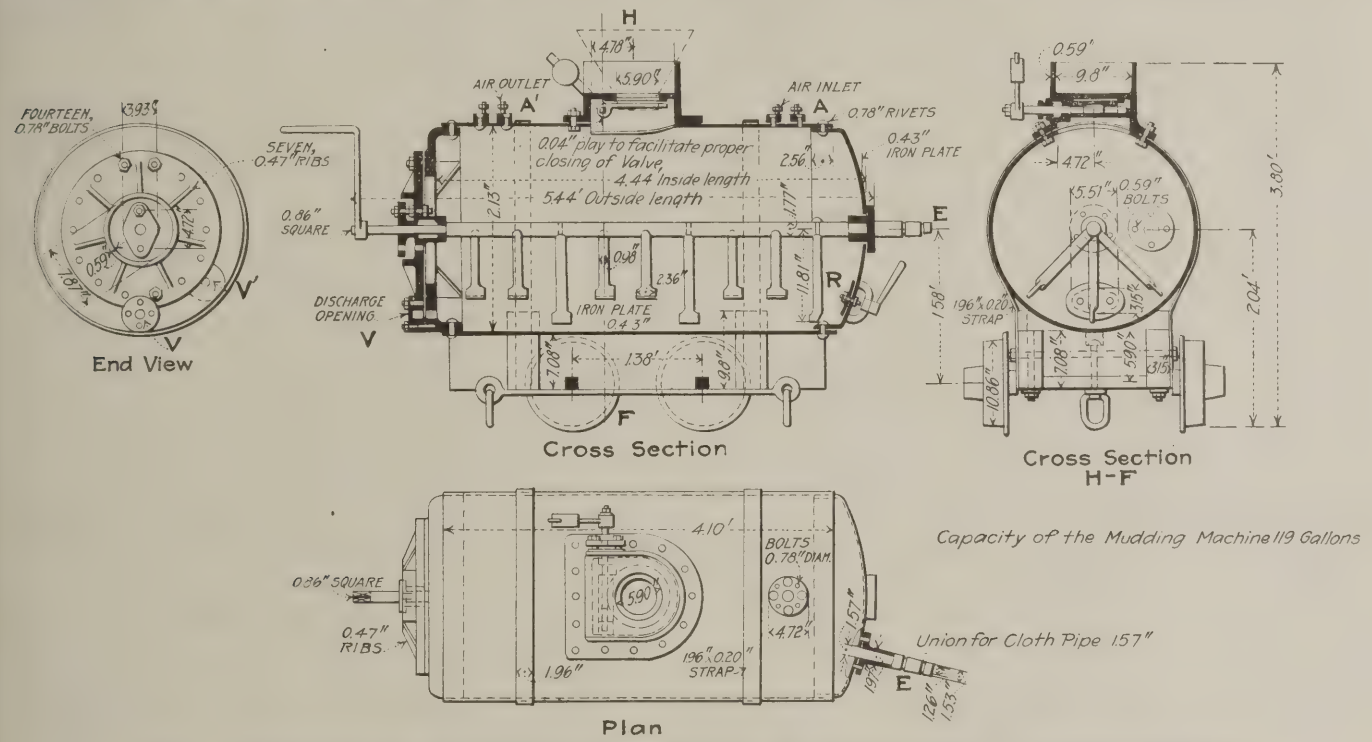

FIG. 1. MACHINE FOR SMOTHERING FIRES IN COAL BY INJECTING MUD INTO THE CREVICES

cold or little heated district, where the flushing is merely preventive. (2) Ribs in such mine areas as it is necessary to keep open, and which are generating combustible gas and developing points of spontaneous combustion. These ribs include those of abandoned roadways where the roadways have not been filled with refuse. (3) Ribs on fire.

The first case is by far the most usual one in the methodical handling of a fiery mine, and here the entrance of air into the borehole does not create any inconvenience. In the second case, air might favor the formation of an explosible mixture. For this reason its introduction must be carefully avoided. In the third case, the air would of course intensify the fire, but the effect of the air would decrease as the flushing material accumulated.

Flushing Is Done by Compressed Air

It is possible to avoid any forcing of air into the coal, but should such an untoward accident happen there are few cases where it would entail serious inconvenience. In the flushing work at St. Eloy, the compressed-air method has been used in all cases, even without using the air outlet, for that adjunct has only recently been added to the flushing tank. Yet no inconveniences were experienced from air forced into the coal.

However, if danger seemed probable in any particular case, an immediate transition from the compressed-air method to the hydraulic method would allow the operator to continue the flushing with entire safety. The same apparatus, in fact, can be used with both water pressure and air pressure; all that is necessary is to have in store materials sufficiently light for such pressure as is available.

If the materials in use are so large that residues are left, the only provision necessary is that the outlet for the muddy fluid be high enough above the bottom of the tank to be free of possible accumulations of the material, the residues of several flushing operations. The old water intake *E*, placed at the mid-height of the tank, may be used as outflow pipe and the water be introduced by the former outlet pipe *V*. With a view to avoiding even that change, which would make it necessary to bring the flushing apparatus to the surface, a second outflow pipe *V′* was added to the flush tank so that the method of operation could be changed without any difficulty by simply transferring the connection from *V* to *V′*.

Use Auxiliary Tank to Keep Air From Coal

Where no light materials are available, it is sometimes necessary to operate under high pressure even where it is essential to keep air entirely out of the coal and where no high-pressure water supply can be secured. In such a case compressed air could be utilized, but it would have to be delivered to an auxiliary apparatus, the water entering the flushing tank under pressure. If a hose pipe were used to connect the two tanks, it would be easy to obtain from its movement a warning of the moment when the air of the first apparatus started to pass into the flushing tank.

At each operation the flushing tank received half a mine car, or 9.35 cu.ft., of ashes or breaker refuse, which occupies space which would accommodate 70 gal. of water. The actual water displacement of the materials, however, will be 20 per cent. less than their volume. What occupies the same volume as 70 gal. of water will displace only 58 gal. of water. The tank holds 119 gal. so, roughly speaking, the volume of water used is equal to the space occupied by the material. With two men, 4 minutes is needed to introduce the materials, 2 minutes to agitate the mixture and empty the tank. Hence it is possible to charge, make and discharge the mud in 6 minutes if the inflow reaches or exceeds 15 gal. a minute. At St. Eloy the inflow of water was slow, and the complete operation required at least 7 minutes.

In practice, this rapidity of operation cannot be attained because of the difficulties in placing the cars loaded with flushing material. Then there are unforeseen circumstances such as obstructions in the pipe lines. As a result the record at St. Eloy hardly exceeded four complete operations an hour, corresponding to about 35 cu.ft. of introduced materials. The volume of air used, measured at the line pressure, is roughly double the volume of the materials; that is to say, it is at most 70 cu.ft. an hour, a negligible quantity.

As stated, the main advantage of the use of compressed air was that it enabled us to utilize materials which were too heavy for use when using such water pressure as was available. But operation with air has made the work three times as quick as with water pressure and has required only one-sixth part of the water needed when water pressure was the motive power.

To establish a comparison between the two plans of operations, the broad outlines of the operation with water may be outlined briefly. The flushing apparatus had a capacity of 119 gal. and an effective head at the flushing machine of from 1.96 in. to 2.75 in.

Operation Under Water Pressure

At each operation, 9.35 cu.ft. of flushing materials, or the equivalent of 70 gal. of liquid, are introduced. The end of the previous operation leaves the flushing apparatus full of water, so it is necessary to empty 58 gal. of water by opening the cock on the discharge line, thus making room for the materials to be introduced which, dumped into the water, will add 58 gal. to the volume of that fluid.

The flushing apparatus is then closed, the agitator is put in motion, and the water-inlet valve is opened. By degrees the materials mixed with the water are carried away. When the resistance of the pallets has sufficiently decreased, the water is shut off. About one-sixth of the charged material remains in the tank after each operation, so the moment suitable for stopping the operation is not clearly defined; but it is better not to extend it too long, as the consumption of water is in proportion to the duration of the operation.

After every third operation, the residues must be cleaned out by the mudhole *R*. The average length of time occupied by a complete operation is 40 minutes, including 5 minutes for emptying half of the tank and introducing flushing material, 20 minutes for forcing mud into the borehole and 15 minutes for cleaning out the residues, handling the cars and miscellaneous unforeseen delays. The speed of operation when the

resistance to mudding is light is 1½ operations per hour, corresponding to 9.35 cu.ft. × 1.5 = 14 cu.ft. of material, from which one-sixth that is residue has to be deducted. As a result only 11.7 cu.ft. of materials per hour are delivered instead of 35.3 cu.ft. with the air method, which works more rapidly and does not leave any residue.

The consumption of water is given by the product of the time the evacuation lasts with the flow of the water current during that time. For that flow we will have a figure close enough, though too high, by taking the flow of the intake current in the empty flushing machine. When we flushed with water pressure, that flow was about 13 gal. (50 liters) per minute, which gives for the 20 minutes of evacuation a flow of 265 gal. (1000 liters), to which must be added half the capacity of the tank, or 60 gal. (225 liters), for the tank must be emptied at the beginning of the operation, and also one-third of a full tank (40 gal.), because the tank must be emptied at every third operation, so that the residues can be cleaned out. Consequently, the consumption of water totals 365 gal. (1395 liters), and this flushes a space of about 9.35 cu.ft., equivalent to 220 liters, or 58 gal.[2]; that is to say, about five times as much water is used as material flushed, whereas with the air method the water used and the material delivered are roughly equal.

Problems Connected with Mining at a Depth in Great Britain

George Blake Walker (president) in his inaugural address before the Institution of Mining Engineers of Great Britain, dealt largely with the future conditions of coal mining. He stated that the seams comparatively near the surface were about exhausted and that as mining was prosecuted at greater depths the rock temperature increased. At one operation near Doncaster the men suffered from boils and anemia, and their working efficiency was reduced 20 per cent.

It is of great importance that the mine ventilation current should have as little effect on the rock exposed in the entries and other mine workings as possible. As airways and entries which have a smooth surface cause less friction to the ventilating current than those which are less smooth, for this reason, it was noted, cement linings on airways had been used largely in some French collieries—notably at Courrières. This practice is said to be quite economical. The airways were roughly shaped to a circular or oval form and were then coated with a shell of cement a few inches thick by means of a cement gun. The principal value of this coating is in preventing leakage of air into the gob and the heating of the intake air from old mine workings or gobs.

In the Doncaster district the seam underlying the Barnsley bed is utilized for ventilation; intake or return airways are driven in this seam independent of the workings in the Barnsley bed. This method permits of the separate ventilation of panels and districts so that, should excessive temperature prevail in a certain section, it could be reduced and the workmen be protected. This system would seem to lend itself admirably to a plan which might include the cooling of the mine air at some future time. Refrigerating apparatus has been considered in this connection as making it possible to reduce the temperature of a large volume of air 10 deg. at comparatively small cost.

Mr. Walker notes that if we have reached a point where underground workers have become inefficient then the human element would have to give way more or less to mechanical appliances. Coal-cutting machines have been in use in English mines for many years, but hitherto this apparatus has been largely confined to the thinner seams. It does not seem that their use has been considered economical in seams thicker than 4 ft., but when these machines are to be used in workings in which excessive temperatures prevail then they likely will be introduced into the thicker beds. Explosives would largely be done away with at great depths as here the coal would break down quite easily under pressure. Furthermore, the animal haulage which has been supplanted by mechanical means in recent years would have to undergo further reduction as the mines became deeper.

In sinking to coal at a depth of 3000 ft. and over a large expenditure must be made for shafts. Shafts as now constructed are made 20 ft. and more in diameter, and two such openings might easily represent an expenditure of $300,000 irrespective of equipment. This development might only be justified when areas of 5000 acres or more would be tributary to the shafts in question. But the difficulties of high temperature would tend to limit the extent of the workings; in this case shafts would have to mine out smaller territory, which might be prohibitive to private capital and require state action. Eventually it would be a question of the cost of mining the coal, making the expenditure not worth while.

The International Geological Congress recently issued a report on the coal resources of the world and estimated the total probable reserve at 7,397,550 million tons. Of this amount Great Britain has one-fortieth, while the whole empire controlled about one-fourth. The fact that the United States, whose competition must be considered more than ever in the immediate future, possesses more than half of the world's supply of coal, makes it necessary to conserve this (Great Britain's) supply. Furthermore, this estimate of coal reserve was based on being able to mine coal to a depth of 6000 ft. from the surface. The British Royal Commission on Coal Supplies settled on a depth of 4000 ft., below which it would not be profitable to mine coal. However, Mr. Walker suggests that these depths are open to criticism and the available quantities of coal were greatly overestimated. The Royal Commission on Coal Supplies reports 39,483,000,000 tons available in Great Britain; if this quantity were reduced by 20 per cent. it would leave 31,586,400,000 tons. As the production of British mines for 1910 to 1914 inclusive was an average of 270,000,000 tons per annum, then the reduced reserve would be exhausted at this rate in 116 years.

In connection with the depth at which mining might be profitably carried on it was suggested that if conditions were unfavorable at 3000 ft. (already practically reached at Doncaster), then it would seem to be useless to estimate at depths between 3000 and 4000 ft.—much less at the greater depths of 5000 and 6000 feet.

[2]Seventy gallons less one-sixth residue, which by chance is the same figure as that given for the water displacement of the flushing material.—[Editor].

Baltimore Coal Trade in 1918

THE year 1918 came into being with weather records the lowest in the history of the Federal Weather Bureau, and nearly twenty thousand homes in Baltimore out of all classes of coal. Industrial Baltimore was so short of fuel that many plants worked only part time, some being forced to close for brief periods because of lack of coal. Even the public utilities ran short, and the words "coal famine" were the mark of a reality and not a mere figure of speech. Many schools and churches suspended for a time. Such was the condition through much of January and February.

The year ended with the glow of peace spreading over the world, with a cancellation of war contracts and with the release of coal for industrial and domestic purposes in such volume that all thought of famine is at an end for the time being.

Of the new year there is not much to relate so far, save that it has all the earmarks of bringing rehabilitation changes to business that must be overcome before the fuel industry is again on a truly stable competitive basis following the release of all Government control. It can be said, however, that the trade holds a confident view for the future. That no firms of real consequence went to the wall during the trying days of the war is a subject of congratulation, and it is the belief there will be a bigger business here in local trade, coastwise and export movement than was recorded in the banner seasons of 1914 and 1915, when the export movement for the first named year ran well over a million tons and for the latter a round two million tons.

Pier Facilities Considerably Enlarged

In the past few years Baltimore has swung into a new position as to the possibilities of modern coal handling. The pier situation here, for instance, is interesting. When Baltimore made its first real bid for export business it had an antiquated pier at Canton owned by the Pennsylvania; now there has been completed there a giant new pier of modern design. The old Curtis Bay pier of the Baltimore & Ohio had its decided limitations; now there is a remarkable pier of modern belting-system handling which alone could dump 12,000,000 tons a year, and which has set world records in loading. It was at this pier that the "Tuckahoe," the ship constructed by the Shipping Board in 27 days, was loaded in two hours and fifty minutes. The Western Maryland's pier at Port Covington was only a moderate factor, and the Locust Point pier of the Baltimore & Ohio was merely a harbor-delivery point of moderate capacity in years gone by.

After the Fuel Administration control and the drop in the immense coal handling here by reason of war conditions the pier business vastly decreased. Curtis Bay kept running on navy, Shipping Board and some coastwise coal when bottoms could be secured; Locust Point and Port Covington were closed, and the Canton pier of the Pennsylvania was used for economy sake by the Railroad Administration to handle all harbor delivery, Baltimore & Ohio, Pennsylvania and Western Maryland shipments. With the splendid pier facilities here of all coals, however, and the prospect of a large export and coastwise trade as soon as vessel bottoms are released for general water movement, Baltimore seems due for the greatest coal-handling records of her history.

Industrially Baltimore too is prepared to go ahead. Many great plants that handled war work and the public service corporations have installed modern coal-handling machinery. One of the finest coal handling plants in the country is owned by the Consolidated Gas, Electric Light and Power Co., of Baltimore, at its Westport power branch. This tower is one of four units of the coaling equipment at the plant. Still another unit is under construction.

Of the immediate past in the coal trade here it is to be recorded that the months of 1918 in this section were about a duplication of the conditions all over the east. Soft coal supply was desperately short all during the winter months, and while some relief came through in the spring, there were constant complications from war conditions and Government control. Changes to jobbing methods, regulation of production as to quality and price changes at frequent periods, priority rules that were set and upset, commandeering—all are too vividly remembered to be repeated at length.

Demand Drops with Signing of Armistice

The signing of the armistice found the soft-coal trade a little easier here as to supply, as most industries had been able to stock up with fuel, even if it was of very inferior grade in many cases. After that time the increasing releases of the better coals caused an easy market, in which there was some price cutting. As a whole, however, the trade rounded out the soft coal year in good form and with good prospects.

The anthracite situation during 1918 was ever a serious one until after the armistice was signed. The year was begun with thousands of homes in this city without fuel, and only the most expert handling of the situation by the retail coal dealers, with approval of the fuel administration, saved a much worse situation. Baltimore ended the real winter season in March pretty well cleaned out of all hard coal. It was estimated that the suburbs and city would need a total of 896,345 tons for the coal year—based on a consumption in 1916-17 of 657,921 tons in the city and 63,428 tons in the immediate suburbs, a total of 721,349 tons. The balance was asked to cover stored shortage, cellar replacement, increased population needs and increased burning by several industries which were included in the allotment. The request was rejected, and Baltimore was allotted 713,316 tons for the city and 61,000 tons for the suburbs. Up to Nov. 11 on this allotment the city and suburbs had received less than 450,000 tons. Because of the two-thirds delivery plan and the fact that many consumers had undoubtedly managed in some way to get practically their full allotment, while the corporation demand for hard coal had cut heavily into the apportionment received, the day of the signing of the armistice found 12,920 homes in the city still without coal, as shown by a public census. Heavy receipts since then, however, have relieved the situation entirely.

With December figures off, they not having been compiled by the local fuel administration, the hard coal situation here by months was as follows:

	Received, 1918	Received, 1917	On Hand End of Previous Month	Tons Delivered	Tons Not Delivered of Two-Thirds Plan
April	67,174	50,681	30,809	69,304	267,761
May	55,757	66,782	32,555	66,928	270,837
June	58,773	64,751	22,968	58,312	263,819
July	49,271	59,929	21,772	55,037	233,434
August	50,750	45,415	16,958	37,582	199,245
September	57,314	44,428	22,276	50,704	162,270
October	45,406	37,178	21,777	57,504	103,081
November	45,618	46,905	35,123	40,135	84,073

During the progress of the war little complaint was heard from the public about price increases, most of the consumers recognizing that freight and wage increases and mounting overhead charges made the moves necessary; but the dealers at the close of the year were feeling the effect of the high rates through cancellation of orders still on the books following the warm weather and the thought in the public mind that the ton price is now so high as to be avoided as far as possible. Comparative prices here for the present market, as set here Nov. 9, and for Sept. 9 and September of 1917, are given herewith:

	Nov. 9, 1918	Sept. 9, 1918	Sept., 1917
Hard, No. 1	$11.90	$10.85	$9.20
Hard, No. 2	11.90	10.85	8.90
Hard, No. 3	12.15	11.10	9.15
Hard, No. 4	12.25	11.20	9.30
Pea	10.40	9.31	8.30
Buckwheat	8.60	8.60	6.70
Lykens Valley, No. 2	12.60	11.55	9.65
Lykens, Valley, No. 3	13.00	11.95	9.90

Deep down in the hearts of the coal men here there is probably little regret that 1918, a year of constant uncertainty, is gone. The retailer had his problems and at times feared that Government regulation would put him out of the running or seriously interfere with his earnings; the jobber had to veritably fight for life at times, but came out triumphant; the operator had so many problems that his troubles were truly legion.

Denmark's Coal Supply

Denmark's fuel problem, states Erwin W. Thompson, United States commercial attaché at Copenhagen, in a recent report, was quite satisfactorily solved during the first four years of the war by a recourse to wood and peat, aided by the well-organized and quick work of Denmark's coal distribution committees. At the beginning of the fifth year of war, says Mr. Thompson, this coal question should be considered again, the more so as the conditions for production and the political conditions abroad do not give Denmark any bright prospects of a good supply for the coming months.

It early became evident, continues the report, that the coal question would be a most difficult one for the entente. In September a London paper said that the coal problem in England was serious. In the beginning of October the British coal controller stated that even if peace came soon, the coal problem would not nearly be solved. England lives from hand to mouth with regard to coal. The supplies are very small, and the military demands are swallowing a great part of them. France is at present consuming 6,000,000 tons more than the normal annual rate, and Italy's demands are very heavy.

It will therefore be understood that the decreased production is keenly felt at home. In the first half of 1918 the production in the United Kingdom was 117,000,000 tons compared with 127,000,000 tons in the first half of 1917 and 140,000,000 tons in the first half of 1914.

If we turn to Germany as the second largest supplier of coal for the Danish market, the prospects are still darker, as the labor problem and transportation difficulties must be taken into consideration. Transportation is the most difficult in the fall, on account of the harvest. This influences the neutral countries, both the Swedish and the Danish import having been on the decline in recent months.

When judging of the coal prospects for the coming winter, these general conditions in the producing countries must be taken into consideration, and some special conditions in connection with the latest foreign political developments. The freight on English coal to Norway was recently reduced from $20.10 to $6.70 per ton, but a similar reduction can not be expected in the Danish trade. A Danish reduction of the coal freight is, however, being contemplated in consequence of the reduction of the insurance premiums. The ship owners have not yet decided to make these reductions, and the importers are looking forward to it with some anxiety because it would mean a loss to them on their stocks. The possible result of this situation will be a decreased import. The British export price of 83 crowns per ton f.o.b. Newcastle for steam coal plus 77 crowns for freight and 14 crowns for expenses and profit to the importer, makes a selling price of 170 crowns ($45.56) in Denmark. It would therefore be desirable if the negotiations now going on could be made to give a favorable result for the consumers without hitting the importers too hard. Then, of course, the question is whether England will not meet a freight reduction by increasing her export price which, among the Scandinavian States, is highest for Denmark.

The prospects for a continued sufficient import from Germany are still darker, is Mr. Thompson's belief. Most of the ports from which Denmark got her supplies are now in the hands of the revolution. German coal is shipped partly from the Baltic ports, partly from the Elbe, Weser and Ems ports. From Emden on the Dutch border and via the Dutch city of Delfzejl several of the most important shipments were made along the North Sea coast up through Kiel Canal. This transportation is hardly possible under the present conditions, and upon the whole it is to be expected that German supplies will be very small for some time to come.

The importation of coal from Germany was one of the most important items in the four monthly trade agreements between this country and Denmark. As the present agreement expired Nov. 31 a meeting was called but had to be postponed because the German delegates could not come, probably because of recent inner political complications. An agreement with Germany will hardly be made before Dec. 1 if the situation in Germany continually develops along these unfortunate lines.

The Danish coal supplies are sufficient for three to four months, but the prospects that the German imports will decrease and possibly cease altogether is a very serious matter, even if a near peace gives hopes of larger supplies from the west.

Six Men Rescued by Breathing Apparatus

By JOHN T. RYAN
Pittsburgh, Penn.

SYNOPSIS—*The fire in the Mt. Braddock mine on Jan. 20 was caused by the caving of the mine roof under a burning slate pile. Fortunately only six men were in the workings at the time. The air was reversed and all the men rescued. Some were in air of breathable, though questionable, quality, but had to be brought out in breathing apparatus because they had to be hauled in a trip through a zone of vitiated return air. Earlier in the day two men with no apparatus, finding that a rabbit was able to breathe the mine air for 20 minutes and live, went into the mine on a car trip. Evidently the rabbit was too slow in succumbing to the impure air to be a safe indicator, and the men stayed in the mine too long and were drawn out dead. The successful rescue men were seven hours in the mine while four of the rescued had been detained underground 24 hours.*

WHAT is probably the most successful and interesting piece of rescue work, and one which demonstrates the utility of the self-contained breathing apparatus, occurred on Jan. 20 at the Mt. Braddock mine of the W. J. Rainey Co., Mt. Braddock, Fayette County, Penn., where six men were recovered alive by the aid of breathing apparatus.

On the morning of Jan. 20 the firebosses at this mine discovered indications of smoke in the return airway, and no men were allowed to enter the mine except six who went to start the pumps and locate the fire. The fire was later discovered by another party, which found that it was located near the outcrop just to the right of the main slope and the air course. The ground beneath a burning slate dump had caved in and the burning material in the dump had ignited the coal pillars.

As may be assumed from what has been already said, the mine is approached by a slope. The active workings are about 1¾ miles from the mine mouth. The main haulage slope is paralleled by the manway, and both the slope and the manway were used for the return of the mine air. The fire was on the intake airway, and consequently the gases generated were all carried through the mine. The Rainey company's officials made heroic efforts to get to the fire and were making headway when the smoke forced them out; most of them were partially overcome by carbon monoxide.

The rescue teams of the companies working adjoining mines were called upon but owing to the condition of the roads their arrival was delayed. Three men from the Orient Central Rescue Station arrived early in the afternoon with breathing apparatus, which they quickly assembled. They entered the mine by way of the main slope and traveled down it about 4000 ft. to the main parting, encountering much smoke.

There they found two men, one unconscious and the other conscious. These men had found a leak in a compressed-air line and had enough presence of mind to remain at that point. The conscious man told the rescue team to give the signal to lower a trip, which was done, and the two men were loaded on the trip by the rescue team; all were hoisted quickly to the surface.

The recovered men were unconscious when they reached the slope mouth and were taken in hand by John S. Struble, inspector for the H. C. Frick Coke Co., who had just arrived with his rescue team. Eventually, by means of artificial respiration and oxygen they were revived. Struble then took charge of the work and the recovery of the other four men later was due largely to his good judgment and untiring efforts.

After looking over the map he decided to change the ventilation and prevent the gases from the fire getting to the section of the mine where the other four men were supposed to be located. His rescue crew, equipped with breathing apparatus, constructed a temporary brattice, a more permanent stopping being then constructed by men without apparatus. Apparatus men remained nearby while the permanent stopping was being constructed, so that they could aid the workmen if help were needed.

Bureau of Mines Rescue Car Arrives

Mean time the United States Bureau of Mines at Pittsburgh had been notified, and five men in a rescue truck left for the scene of the accident 20 minutes after word was received. They made record time until they struck a mud road about five miles from the mine. There the truck became mired. The crew was picked up by Stephen Arkwright, inspector for the H. C. Frick Coke Co., and J. T. Ryan, of the Mine Safety Appliances Co., of Pittsburgh, who were on their way to the mine in another car. They arrived about the time Struble had completed the brattices, the purpose of which was to direct fresh air through an overcast to the left side of the mine.

An organization was then perfected to take charge of the outside, and Struble, Arkwright and D. J. Parker organized an exploration party of ten men equipped with breathing apparatus, safety and electric lamps, and a canary. They entered the mine, following the direction of the intake as newly established. In following the fresh air they were required to travel a circuitous route where the going was bad, but they proceeded carefully and marked the route thoroughly with chalk in case they had to return the same way; finally, after 2½ hours of travel, they came to the main haulage slope immediately below the main parting.

Before the party proceeded through the door which separated the intake and return, two of the men went ahead and examined the return air with safety lamps and the canary. The air in the return at this point being clear, the party went through the door to the slope and located a telephone and made a report to the outside. After taking a rest they proceeded down the left slope, at which point was a pump. It was thought

that two of the men would be found there. After going about 600 ft. they saw a light 400 ft. ahead, apparently in the hands of a staggering man.

They approached it cautiously and found Charley Lerch, who fell to the ground just as they reached him. He was given oxygen from one of the breathing apparatus and quickly revived. He was able to tell that his "buddy" was back somewhere along the slope and unconscious. Arkwright, McCaa and Ryan took him back to the firebosses' shanty at the parting and gave him stimulant and oxygen, which brought him around in good shape.

Others of the party then proceeded down the slope and found Elmer Matthews about 3000 ft. from the parting, or about 2000 ft. beyond the first man recovered. By dint of hard work they revived him with artificial respiration and oxygen, but he was unable to walk and had to be carried back to the parting, where he readily responded to first-aid treatment. These men were unable to give any information as to the location of the other two men, so after a conference it was decided that these men were evidently in the vicinity of the other two pumps, which were located at the bottom of the right-hand slope.

Arkwright, Parker and Ryan, with five men equipped with apparatus, proceeded down the right-hand slope to explore for the other two men, leaving the other members of the rescue party to look after the two just recovered. The latter party communicated with the surface and had a trip sent down with blankets, stretchers, hot coffee and other stimulants. Arkwright's party located the two pumps, but found no trace of the men other than a safety lamp.

After exploring all the working places, they started out along the manway and found James Russell, who was partially conscious and quickly responded after oxygen was given him. He had no idea of where he was or how long he had been there and could give no information about his companion. Two of the party remained with him, and the others continued up the manway and found Frank Largon about 300 ft. beyond.

He was in bad condition, and in consequence he did not respond to treatment for almost a half hour. While three of the party worked on him, the others returned to the main parting for stretchers and assistance, upon the arrival of which the two men were carried out to the parting and were given stimulants and plenty of oxygen.

Did Not Want to Be Resuscitated

Largon had made up his mind that he was going to die, and he apparently did not want to change his fate. He refused to breathe oxygen, and at one time the whole party was working on him, rubbing him, holding safety lamps around him to keep him warm, meanwhile trying to get him to take stimulants and oxygen. He finally wanted to fight Struble, and the anticipation of this pleasure was sufficient inducement for him to decide to get well.

Now came the problem of getting these four men to the surface, a distance of 4000 ft. The most direct route was by way of the slope. It was plainly evident that on account of falls, partially closed passages and the exhausted condition of the rescued men, it would be impossible to carry the rescued back over the route the rescue party had traveled on entering. The rescuers were also confronted by the fact that, while the air was good on the slope at this point, about halfway up the slope the return from the fire section joined the return on the haulage slope.

To determine the condition of the air it was decided to send a canary and some safety lamps to the surface on a car trip. This plan was communicated to the outside to Mr. Sincocks, general superintendent of the W. J. Rainey Co., who had been overcome earlier in the day, but who was again back on the job. As soon as the trip reached the surface Sincocks examined the canary and found it had been overcome, and the safety lamps had been extinguished.

This information was communicated to the party underground, and after a conference it was decided to have additional rescue apparatus sent down for the four recovered men and for those whose oxygen was partially exhausted. It was also decided that a fresh canary and additional safety lamps should be sent in so that the condition of the air could be tested again when necessary. Fortunately there was plenty of equipment on hand, as additional apparatus had arrived from the Orient Central Rescue Station, and Rescue Car No. 6 of the United States Bureau of Mines had just arrived from Houtzdale, Penn.

Rescued and Rescuers Prepare to Leave Mine

The foregoing program was quickly carried out. When the trip arrived at the parting the canary had been overcome, but the safety lamps were still burning. The four rescued men were then seated comfortably in separate cars. Apparatus was adjusted on them, and two of the rescue crew were assigned to each car in which the men were placed. All the apparatus were tested carefully, and after eleven of the party were in their places, McCaa and Zorn examined each apparatus and turned on the oxygen, then examined one another's apparatus and got aboard.

Struble, at the telephone, gave instructions to hoist in two minutes. (Those two minutes seemed like an hour.) The trip started, and in 10 minutes the fourteen men, all wearing breathing apparatus, reached the surface in fine shape. They emerged from the mine at 8.10 a.m., Jan. 21. The four rescued men had been underground just 24 hours, and the rescuers seven hours, having entered the mine about 1 a. m.

The rescue crew was composed of the following men: Stephen Arkwright, inspector, H. C. Frick Coke Co.; John Struble, inspector, H. C. Frick Coke Co.; D. J. Parker, mine safety engineer, United States Bureau of Mines; Bert Dwyer, George McCaa and E. D. Gardner, mining engineers, United States Bureau of Mines; J. H. Zorn, rescue foreman, U. S. Bureau of Mines; J. T. Ryan, Mine Safety Appliances Co., Pittsburgh, Penn.; E. N. Barrett, H. C. Frick Coke Co., Footedale Rescue Team; S. J. Cornisky, H. C. Frick Coke Co., Leisenring Rescue Team.

The rescue crew from the Orient Central Rescue Station, who rescued the first two men, was composed of Mike Sopchick, Frank Krum and August Klause, and was under the direction of Charles Opperman, who is superintendent of the Orient station. These men had received training under the Bureau of Mines only the previous week, and they deserve credit for their heroic and successful work in face of great personal danger.

The one unfortunate incident in connection with this accident was that during the morning of Jan. 20 two men attempted to enter the mine without breathing apparatus. They were let down the slope on a trip of cars and when hauled out 15 minutes later were dead.

It appears that prior to their entering the mine a rabbit (in the absence of a canary) had been sent down on a trip and when withdrawn some 20 minutes later was found to be all right. These incidents forcibly impress the fact that a canary is the only dependable medium for detecting carbon monoxide, and also that men should not do exploratory work about mine fires unless equipped with self-contained breathing apparatus or a canary, preferably both.

The work of the rescue parties who recovered the six live men demonstrated what can be done with self-contained breathing apparatus when in the hands of experienced mining men who are also thoroughly trained and familiar with the apparatus.

All the members of the rescue party that recovered the last four men were equipped with breathing apparatus, but in their underground explorations they were able to travel about 24,000 ft. in fresh air without having to use that equipment. When the four men were found an unusual situation had to be met, for, while the air was breathable in the remote workings where the men were located, there was yet such a quantity of carbon monoxide on the main slope that the canary sent out by the rescue party was killed in the short space of time (10 minutes) in which the trip was hauled up the slope. For this reason it was necessary to put breathing apparatus on the rescued men to get them to the surface.

Orient Central Rescue Station the Result of Operators' Cooperation

By L. U. Leslie
Uniontown, Penn.

Fifteen coal and coke companies in the Connellsville region recently united in the establishment of a central mine-rescue station with teams numbering 200 men. These men are responsible for the safety of 8000 miners employed at the operations. A two-story brick building has been constructed and equipped with mine-rescue apparatus, and the station is in permanent charge of Charles Opperman, Jr., in the capacity of captain. Mr. Opperman holds state certificates for both first-aid and mine-rescue work.

The establishment of this central mine-rescue station is held to be a substantial step forward in the advancement of safety in the coal mines. It places under unified control an important phase of coal mining and permits speedy mobilization of the relief facilities of all the companies interested within a short time in case of disaster. The station is equipped with a heavy motor truck, which, carrying full equipment, is capable of reaching any mine belonging to any member of the organization within a half hour after the receipt of a call for help.

Captain Opperman is located permanently at the rescue station. He is charged with the responsibility of keeping the equipment of the station available for immediate use; in addition, he is instructor in mine-rescue and first-aid methods. Mine-rescue teams have been organized for some time at the various operations, but the new plan places all teams under the command of Captain Opperman. He is now giving instructions to teams from the various operations. These teams are composed of from 5 to 10 men each and are required to report regularly for instruction and drill. At the expiration of their training the men will take examinations, and those who show that they have mastered the principles of their work will be given certificates.

Although the organization is complete and the work of instruction already started, other operations in the region are not excluded from participating in the benefits of the mine-rescue station. The trustees and executive management of the station stand ready at any time to receive the application of other operators in the region for admission into the united mine-rescue organization. Operations now included in the mine-rescue organization are the Orient Co., the Fayette Coke Co., the Uniontown-Connellsville Coke Co., the Tower Hill-Connellsville Coke Co., the Thompson-Connellsville Coke Co., the Struthers Coal and Coke Co., the Connellsville Central Coal and Coke Co., the Brier Hill Coke Co., the Taylor Coal and Coke Co., the Crucible Fuel Co.. the Consolidated Coke Co., the Puritan Coke Co., and the Lincoln Coal and Coke Company.

Material advantages leading to reduced rates for workmen's compensation premiums were one of the leading factors in the organization and establishment of this mine-rescue station, but the operators were also moved by a desire to surround their men with all possible safeguards against accident. The knowledge that a competent relief organization is at all times ready to respond to a call for aid has already served to improve the spirit of the miners. Their interest has also increased in mine-rescue and safety methods.

The building in which the rescue station has its headquarters is erected at Orient, the mining town of the Orient Coke Co., and is known as the Orient central rescue station. The other operations in the organization are in close proximity to the headquarters, in what is known as the Republic district of the region.

The apparatus is housed in a specially constructed two-story brick building the plans and specifications for which were approved by the Bureau of Mines. The building has been inspected and sanctioned by the state insurance board. It is equipped with ten sets of Fleuss-Proto mine-rescue apparatus and all necessary supplies.

Pittsburgh to Receive More Power

Carl W. Schleuderberg, of the Westinghouse Electric and Manufacturing Co., declared at a recent local meeting of the American Electrochemical Society, held at Pittsburgh, Penn., that some large interests were planning for the construction of huge electric plants both at the mines and near available water power. These plants would develop some 700,000 kw. It is expected that the plants thus established may be able to produce current at prices as low as those established for Niagara or any other power in the country. This will be done though there exists at no point a source of power like that at Niagara Falls, which produces about 500,000 horsepower.

Who's Who in Coal Mining

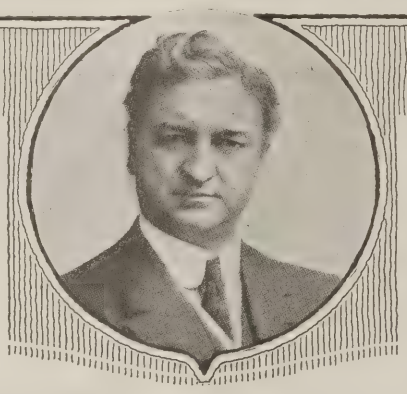
THERE is a dynamic young man down in West Virginia who is carving an important niche for himself in the coal industry's hall of fame. His name is Walter H. Cunningham, and besides acting as secretary of the West Virginia Coal Association he finds time to serve as the secretary-treasurer of six independent coal companies and still do a lot of professional work as a consulting engineer.

WALTER H. CUNNINGHAM

Some men are just successful; nobody knows exactly why. Others stumble blindly into the doorway of opportunity and manage to forge ahead without showing evidences of great virtues. A few men are downright lucky and land on a road where the traveling is comparatively easy. But the case of Walter Cunningham forms no parallel with the foregoing examples. That he has succeeded in a gratifying fashion for a man so young cannot be doubted. That he has gained the honest respect of his West Virginia and Kentucky associates in the mining game is likewise true beyond peradventure. It is further a fact that his climb to a position of importance has come without assistance or pull.

In such a man there are always certain qualities that stand forth prominently and form the foundation of his individual success. So it is with Cunningham. His prime virtues are optimism and imagination. The first creates in him a cheerfulness that is contagious and that surrounds him with a host of friends. The second gives him an outlook on life that extends far beyond the boundaries of conventional engineering practice.

Most technically trained men are so matter-of-fact that their natural enthusiasm with reference to the average industrial project has been entirely subdued, if not wholly eliminated. Mr. Cunningham is no less a conscientious and careful engineer because of his ability to see possibilities that are yet in the making.



Difficulties cause no despair in his heart, for they are always met with hope. He is ever cheerful because he has beliefs—belief in friendship and belief in all the decent things that go to make living worth while. Walter Cunningham's smiling countenance provides him with a key that opens all doors. Those who meet him are impressed with the thought that he must be successful in order to be so happy. This fact inspires confidence and smooths roads that would be rough traveling to the fellow having less buoyancy. The kind of cheerfulness possessed by the young secretary of the West Virginia Coal Association is the type that has excellent wearing qualities. For this outstanding virtue was clearly in evidence back in 1899, when young Cunningham entered Lehigh University, filled with an ambition to become a great mining engineer. He is today a living proof of the idea that a happy disposition and a whole-hearted cordiality are the very best tonics for the mental and physical constitution of a man. While many virtues defer the day of recompense, the spirit of cheerfulness pays cash down.

Not yet 40 years of age, his life has been a busy one ever since those vacation days when as a youngster he earned his first dollars working in and around the mines in Pennsylvania. His earliest important work was with the Davis Coal and Coke Co., in 1906, as a mining engineer in Maryland and West Virginia. Leaving this company, he moved to Kentucky, where he served first as a manager of mines and later as general manager of a corporation producing a large annual tonnage of coal. This varied career has given him an understanding of mining, both from the viewpoint of the engineer and of the operator. It is for this reason, as well as his famous smile, that he has formed connections with many coal companies, and that his services have been in such wide demand for advice along expert lines.

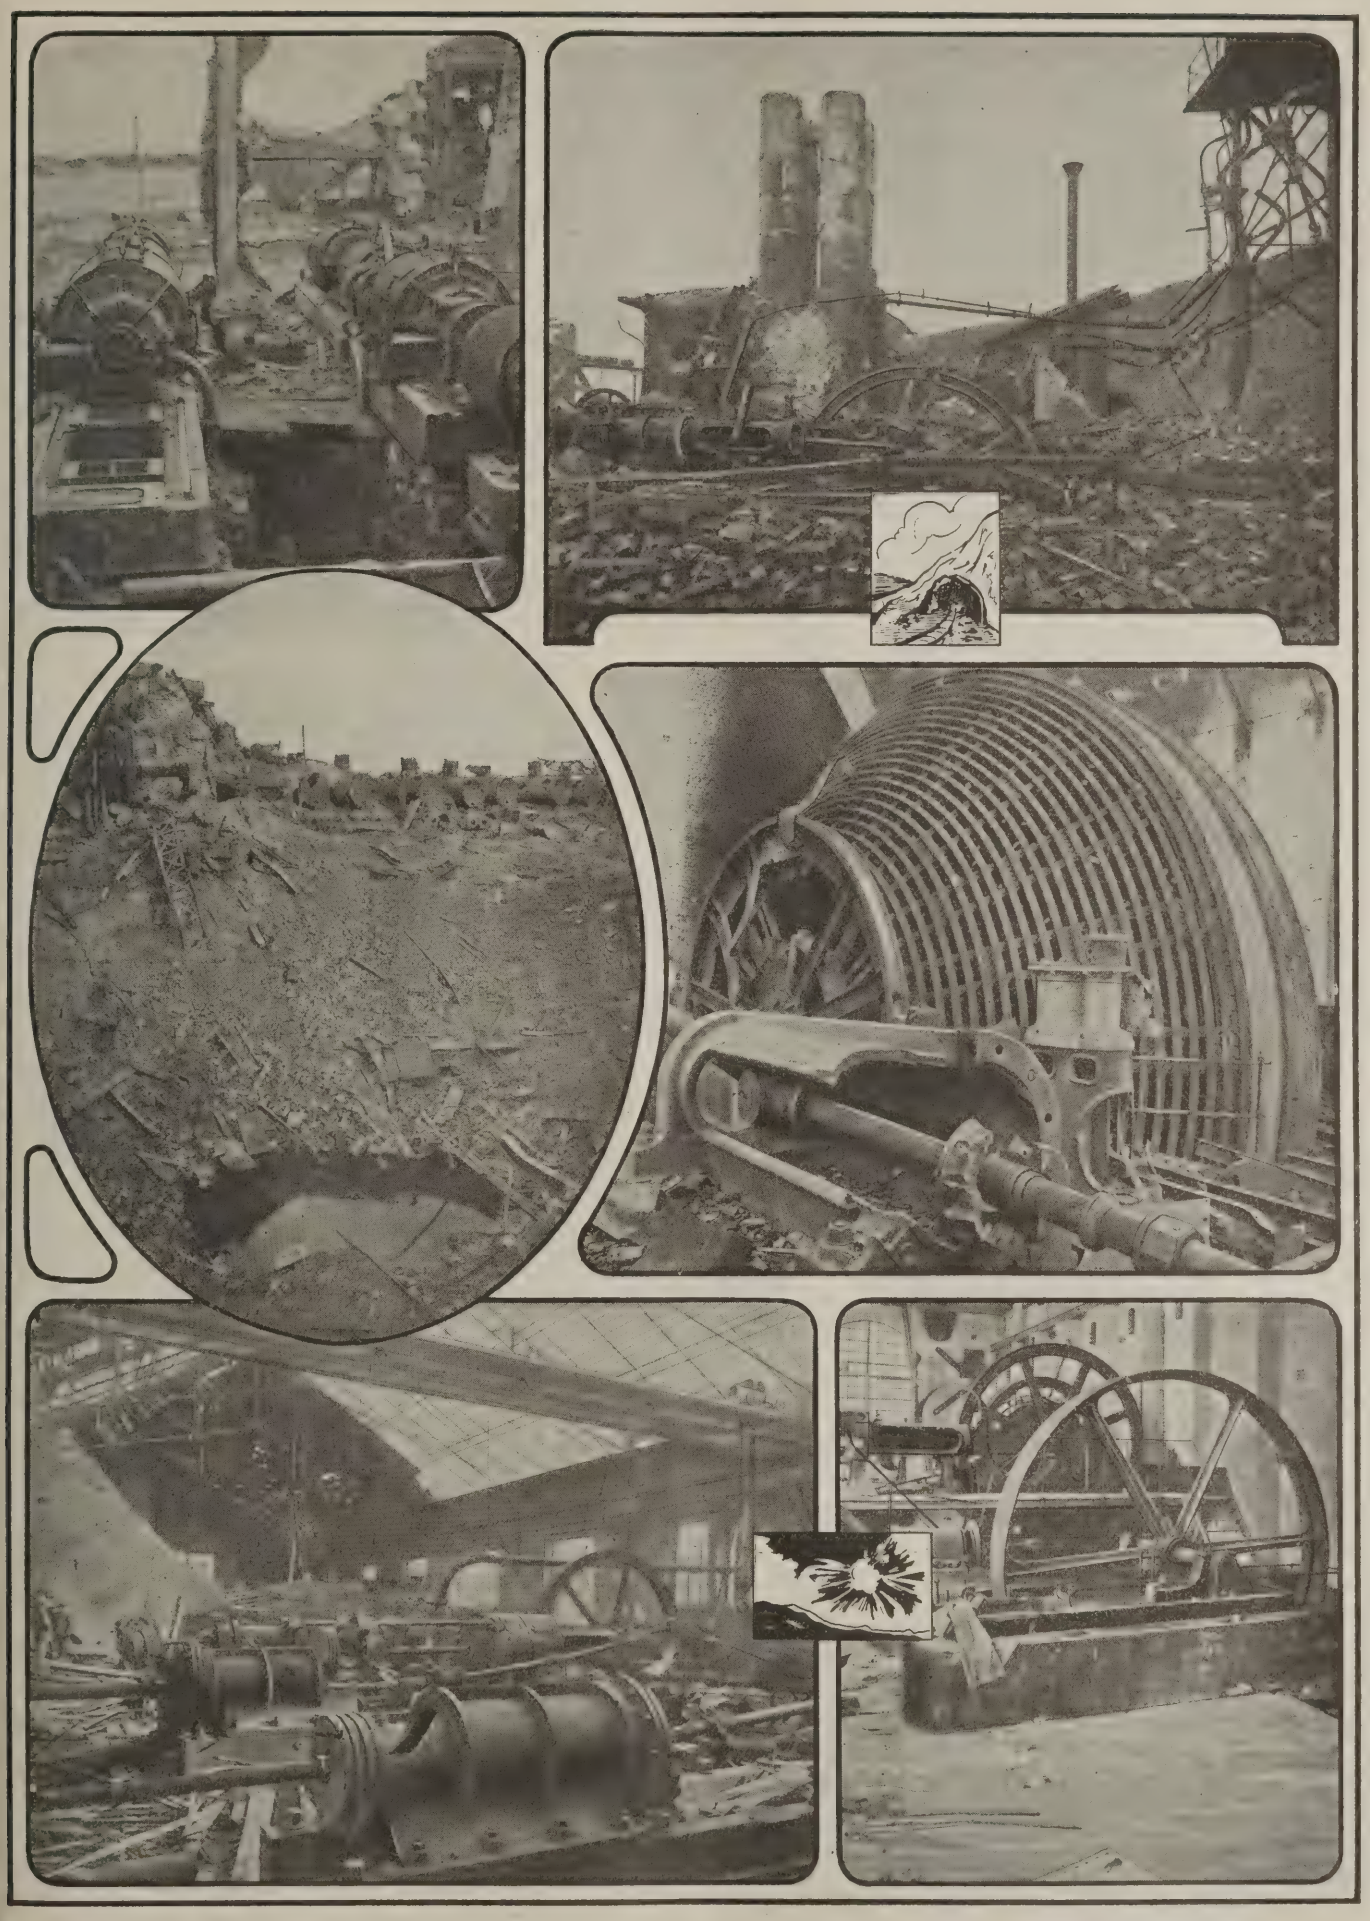
Walter Cunningham is not the kind of man who can never see a cloud, but rather the sort of fellow who can see both the cloud and its silver lining. He has attacked life strenuously and has perfected the art of laying all emphasis, not on what has happened, but on the ends and aims that lie ahead. If he has served his chosen industry with greater credit than the average man, it is because he has founded his philosophy of life on the sound logic that no calamity is ever insurmountable; no sky is ever so bleak but somewhere, sometime, the sunshine will break through.

The Coal Industry of France

By ARTHUR J. BALDWIN, Vice President McGraw-Hill Co., Inc.

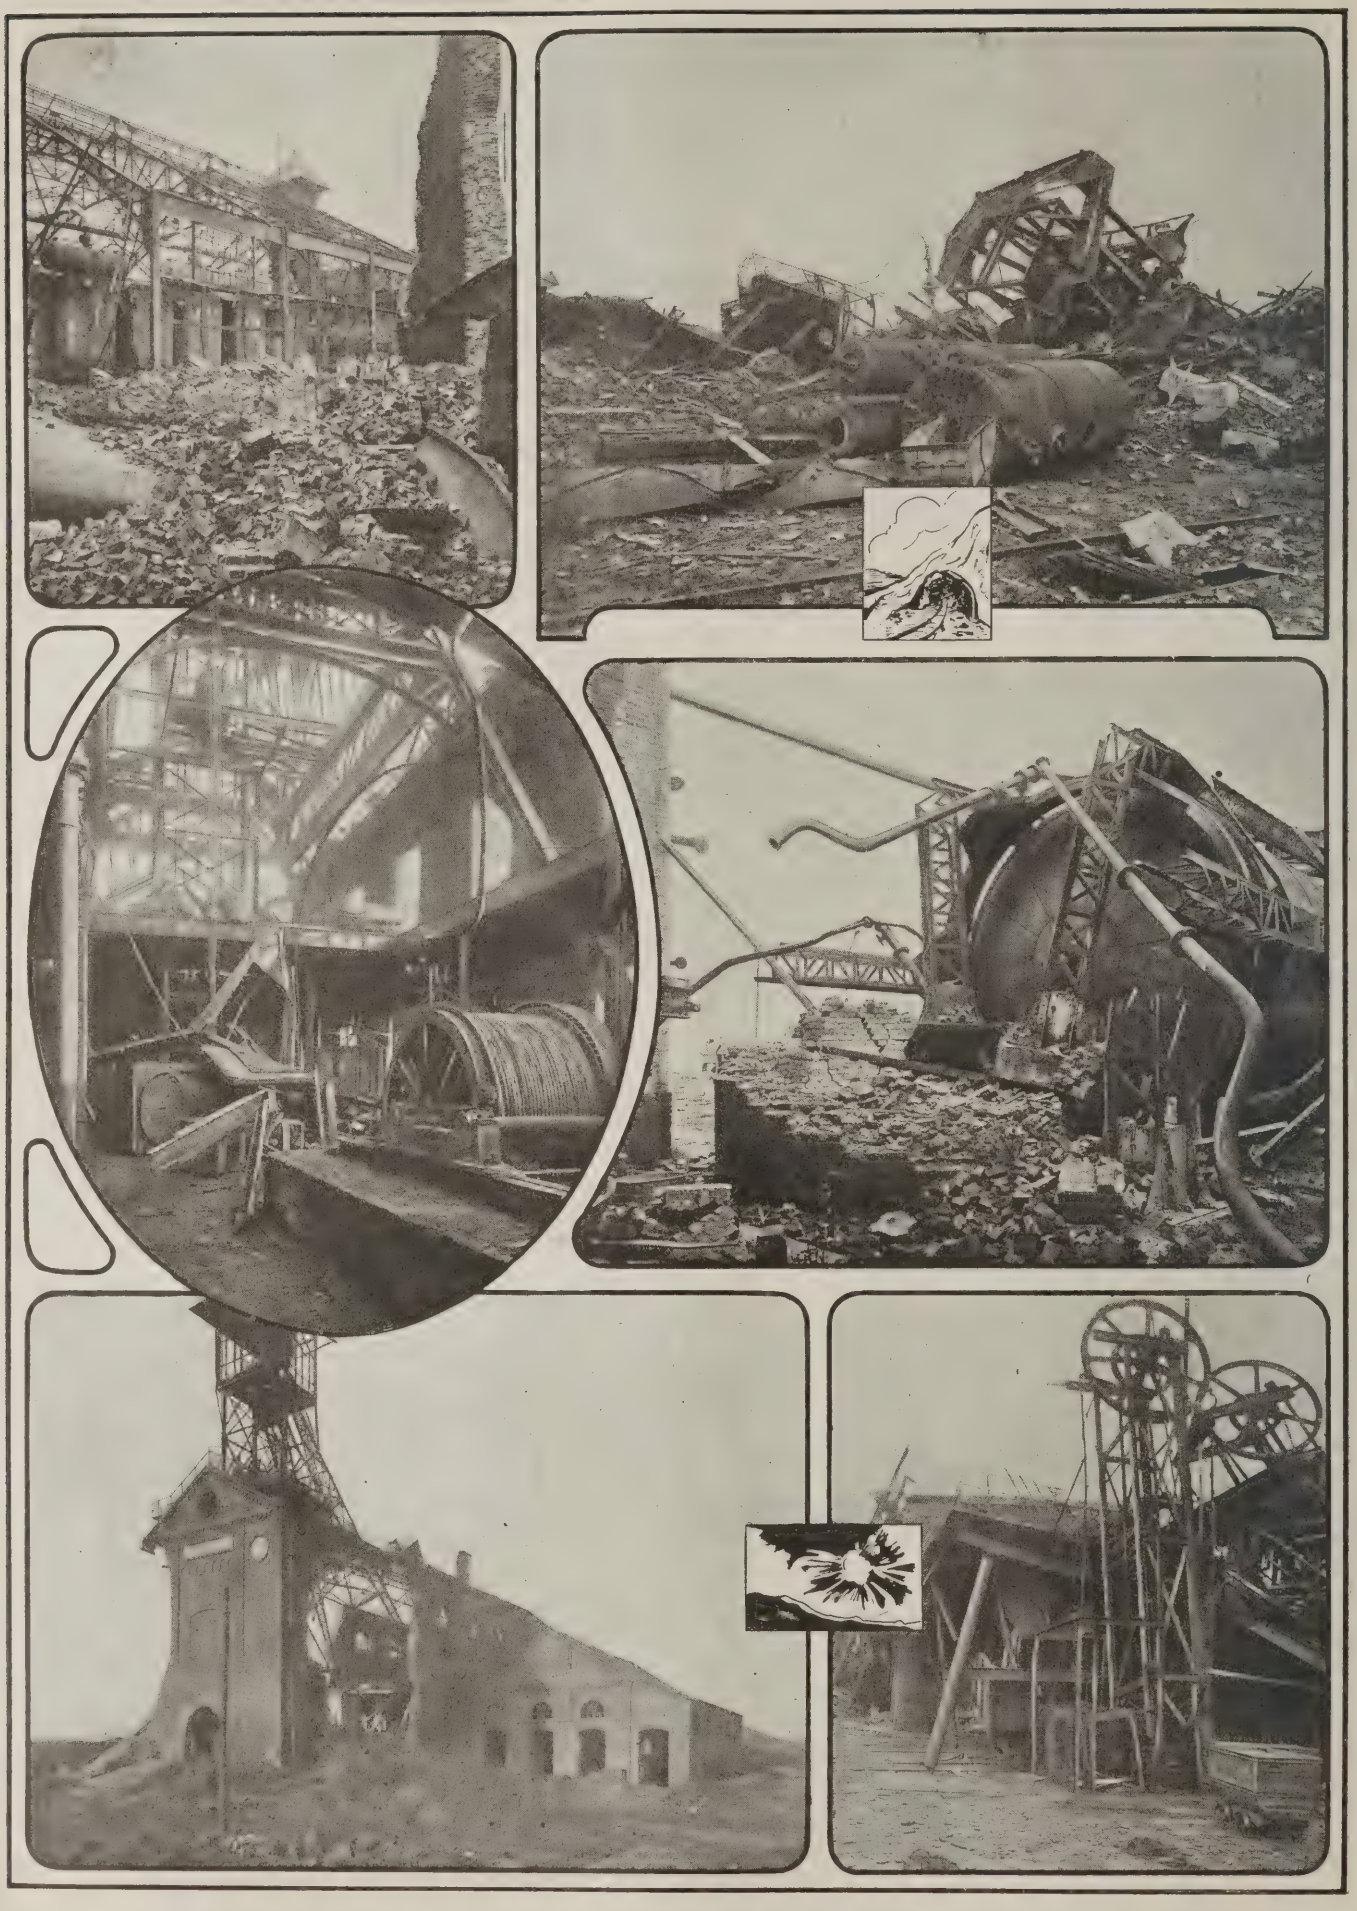
I HAVE seen Lens — the center of the great coal industry of northern France. Through the courtesy of the British General Staff, and as a guest of the British Ministry of Information, I was taken over the battlefields where Lens once stood. Lens is the name of the city that is the center of the great coal-producing region which bears that name. In this district before the war were numerous villages and towns where the miners who worked in the collieries were housed. Approximately 180,000 people inhabited the region. They are all gone. Their homes are gone. The mines where they used to work are utterly destroyed.

Germany seized these coal fields on her initial drive in 1914. The conflicting armies knew well the value of these fields, and a mighty struggle took place for the possession of the mines. German soldiers were billeted in the cellars. German artillery was hidden in the towns. German pill-boxes of solid concrete were constructed in some of the homes to repel the infantry attacks. This made the houses and towns a target for the British artillery.



And so since 1914 there has been almost a constant rain of shells of all caliber, until the whole region is devastated, and nothing remains but masses of ruins. What the artillery did not destroy well-planned German mines accomplished. The shafts were blown up, underground workings destroyed, and water was diverted so that the mines were flooded.

Nearly all of the coal produced in France is bituminous of a good quality. France has little anthracite and is also short of coals for making gas and coke. The coal fields of France have a total area of nearly 1200 square miles. The territory, or rather the coal basin in which Lens is located, is from 5 to 10 miles wide and covers an area of more than 400 square miles. In the pre-war period this district furnished approximately 70 per cent. of the entire French production. The Lens region also was the chief byproduct coking center.



The greater part of the coal was produced from beds that lie more than 1000 ft. below the surface. A number of the shafts exceed 3000 ft. in depth. At many of the collieries 10 and even 12 separate and distinct seams of coal were worked. One of the beds in the vicinity of Lens averaged 23 ft. in thickness, while at a number of mines the seams were successfully worked when they did not exceed 18 to 20 in. in thickness. The output per individual employee in the French mines was never equal to the large production of the individual American miner. In 1913 the average production of each French coal miner was slightly more than one ton per day. Many problems occur in mining the French coal seams that are not common to American practice. The thinness of many of the beds makes it desirable to employ the long-wall system of mining. But even this plan of working is rendered difficult in places, due to the deep pitching of the coal. Many of the seams are overlaid by a weak shale roof, and safe mining is only carried on by the employment of an extensive and complicated system of timbering. At many collieries the roof is sustained through an elaborate system of flushing solid material into the worked-out sections of the seam. All main gangways and important entries are protected by brick or concrete masonry.

As is evident from the accompanying photographs, the surface construction is largely of steel. The power plants, washeries and tipples were modern in every respect, but the underground methods of mining as a general rule have not advanced rapidly in recent years. Nearly all of the mining is hand work, and it will be one worthwhile result if in the rehabilitation of the French collieries ancient practices are abandoned, and mining machines and other mechanical devices are introduced. Here lies hope for American manufacturers.

The question is asked—When will the mines again be opened? The difficulty is this: There are no railroads for transportation; there are no workmen; there are no places for housing the workmen. The people who left there have been scattered, and there is at present no incentive for them to return. There is nothing that can be salvaged from the work of past years; the whole region must be reconstructed anew.

"Shafts were blown up, underground workings destroyed, and the mines flooded"

"The whole Lens coal region is devastated, and nothing remains but masses of ruins"

"Nothing can be salvaged, the whole region must be reconstructed anew"

New Apparatus and Equipment

Kerosene Thawing Devices Serve a Number of Useful Purposes

The Aeroil Coal-Thawing Outfits, Inc., of 1 Broadway, New York City, has recently placed on the market two thawing devices similar in purpose and principle of construction but varying in details of shape to suit convenience of application. The first of these is intended especially for thawing out cars filled with frozen coal. It consists of large twin blast torches, burning kerosene, built to direct their flames upward and drawing their fuel supply from a common pressure tank.

This outfit consists of a pressed steel tank of 10 gal. capacity provided with the necessary hand air pump, pressure gage, air and fuel regulating valves, hose, extension pipes and the two burners; also the necessary instructions. It is stated by the manufacturers that one man can easily operate six of these outfits and that each will thaw out a car of frozen coal in from 30 minutes to 2 hours, depending on weather conditions. Frozen car doors may be opened in about 10 minutes.

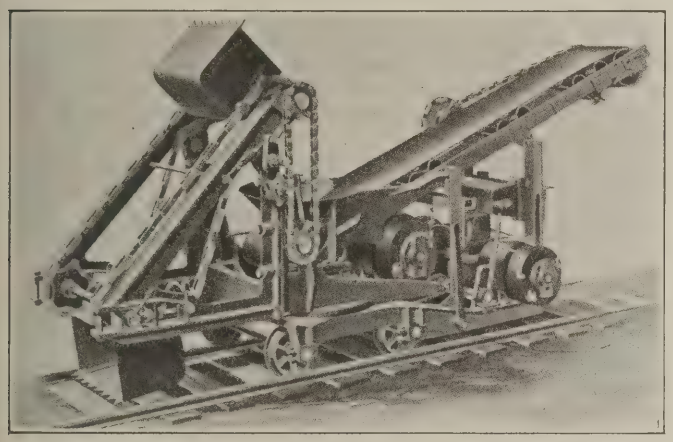
The second piece of apparatus is similar to the first except that it is smaller (5 gal. tank), has but one torch intended to be held in the hand, and is built for thawing out coal chutes, hoppers, gates and the like; also for melting ice on switches, ladders, etc., thawing out frozen air and water pipes, and for similar uses. It may also be used for brazing, welding and heating generally. This torch may be so manipulated as to be entirely safe and not detrimental to woodwork. Its use insures not only an efficient means of performing various thawing operations about the mine but entirely avoids the danger incident to wood fires arising from flying sparks or blowing coals.

TWIN TORCHES THAWING OUT A COAL CAR

SINGLE PORTABLE THAWING TORCH

Mine-Car Loader with a Bucket Conveyor for Scooping up the Mineral

The mine-car loader illustrated herewith is well adapted for certain mining conditions. It consists of three parts—the truck, scooping mechanism and the elevating conveyor. As will be seen, the motion of neither of the two moving parts last mentioned is reciprocating, but continuous. As there are two scoops making synchronous passage from the coal pile to the point of dumping and back to the coal pile, no time is lost. The travel of the buckets is so directed by sprockets that when a bucket is discharged it is promptly withdrawn clear of the hopper head.



The scooping mechanism is so pivoted that it can dig to the side as well as in front of the machine. The material, however, on being delivered to the conveyor, reaches the car behind the loader no matter at what angle the scoop may be working. The machine is self-propelled and so dimensioned that it can easily be moved around the mine. It will load at the rate of over a ton a minute and may be operated by unskilled labor.

While too high for thin seams, the over-all vertical dimension being 6 ft. 7½ in. with one bucket at the highest position and 5 ft. 6¾ in. with the buckets at mid positions, the whole equipment is compact, rigid

and durable. The three parts—truck, digging head and conveyor—can readily be dismounted and as readily reassembled. Thus the machine can easily be taken underground and moved from level to level.

The levers for operating the loader are located at one side and thus the operator is in full sight of the several movements. He has, however, nothing to do but keep the machine close up to the coal pile and swing the shovel from side to side of the roadway as needed. The loader is fitted with motors wound for 230 volts direct current, and these provide power for all operations. The motors are entirely inclosed, and all chains and gears are protected in use by suitable guards. The framework is of steel, the digging head is mounted on a large ball bearing, and all parts are protected as much as possible against dirt and water. All chains are provided with take-ups, and the digging edge of the bucket is filled with renewable tooth sections.

The maximum overall length is 15 ft. 9 in.; the track gage is small (only 24 in.), but that could readily be increased. The capacity of the machine is 1.75 tons per minute with full buckets, and the average capacity is 45 tons per hour. The weight of the complete machine is 4 tons.

VIEW OF McDERMOTT SHOVELING MACHINE

It is claimed for this machine that it eliminates the shovel idea. There are those that feel that the appropriate movement of a machine is not a backward and forward motion, but a continuous action. The first locomotives were to have feet which would push the carriage along the track, much as the bicycle in the early days was propelled by an occasional thrust of the foot. "What could we do better than imitate nature?" was the reflection of the earlier inventor.

The first idea of the flying man was to imitate the reciprocating wing movement of the birds, but continuous action is better suited to airplane machinery than any other, and the propeller works on that principle. The first idea of the steamboat designer was to propel oars reciprocally like an oarsman, but the rotary propeller, either a paddle-wheel or a screw, was finally thought to be the only solution of the problem. Only the continuously running flywheel saved the steam engine from comparative failure, and even today the steam turbine with its continuous action bids fair to put the reciprocating engine, despite its continuous-action parts, out of business. However, there are exceptions, and reciprocation, in the drill and the mining machine, the cage, elevator and steam shovel, still takes a highly successful place in the mechanical arts.

Other advantages claimed for this machine are that the material is not thrown onto the conveyor belt but is delivered to a hopper, and that the loader and car remain stationary during the digging and filling. Charles A. Lawrence, general superintendent of four iron mining companies in Michigan, whose address is Palatka, Mich., has been loading medium coarse iron ore with this shovel for 18 months, and he states that in two to four hours 75 to 100 tons can be handled by three men. In loading by handshovels a man will handle on an average about 15 tons per day. The shovel is manufactured by the Wellman-Seaver-Morgan Co., 7000 Central Ave., Cleveland, Ohio, and is known as the McDermott continuous twin-scoop loader.

Legal Department

INJURY THROUGH FALLING ROCK—In an action by a miner to recover damages for injury sustained through a fall of rock from the roof of an entry in defendant's mine, plaintiff's omission to make an inspection was no defense, in the absence of a showing that such inspection as he was required to make would have disclosed the defect resulting in the accident. And where a miner is required to remedy defects in the roof of a mine only when so directed by a superior, it is the operator's duty to furnish the means of obviating such defects as may be encountered. (Alabama Supreme Court, Dodd vs. Choctaw Coal and Mining Co., 79 Southern Reporter, 54.)

RIGHT TO ADVANCE PRICE—Prices were quoted on coal on the following stated condition: "All quotations are for immediate consideration; that is, subject to prior sale, also any advance as outlined by the Fuel Administrator and conditions generally existing in the coal fields over which we have no control." It is held by the New York Supreme Court, in the case of Carlisle vs. Lovell, 171 New York Supplement, 996, that orders for coal have been accepted by the sellers, the prices fixed by them could not be advanced to meet new prices fixed by the Fuel Administrator before delivery, although the new prices became effective before the selling jobbers placed orders at the mines to fill the particular contracts. No reason appears why the jobbers might not have presented the buyer's orders as soon as received, and thereby bound the owners at the mines by valid contract, which would have protected them in turn in the performance of their contract with their customer.

PRECAUTIONS AT ABANDONED SHAFTS—A section of the Oklahoma coal-mining laws declares: "In all mines where operations are temporarily or indefinitely suspended, the superintendent and mine foreman shall see that a danger signal be placed at the mine entrance which shall be a sufficient warning to persons not to enter the mine, and if ordinarily circulation of air through the mine be stopped, each entrance to said mine shall be securely fenced off and a danger signal shall be displayed upon said fence." Another section of the statutes makes a mine owner liable for injury sustained by another through violation of the quoted provision. In the recent case of Pinkston vs. Whitehead Coal Mining Co., 175 Pacific Reporter, 364, it is decided by the Oklahoma Supreme Court that the statute operates for the benefit of all persons on such mining premises, whether they be there with the consent or permission of the mine owner or not. And it is held that an operator may be held liable for death of a young man who descended into an unguarded shaft to recover a piece of jewelry dropped by a young woman companion, and who was suffocated by mine gases.

Anthracite Prices and Many Other Restrictions Suspended

Maximum prices on anthracite coal, together with all other coal and coke regulations except three, were suspended effective Feb. 1, in a blanket order issued on Jan. 31 by Fuel Administrator Garfield.

The only restrictions not suspended, as to coke and all coal, are: Those requiring that contracts be made subject to maximum prices if reinstated, subject to cancellation by the Fuel Administration and subject to requisition or diversion of coal by the Fuel Administration; those prohibiting reconsignments of coal; those requiring shipments of coal to tidewater to go through the Tidewater Coal Exchange. The tidewater and reconsignment regulations were retained at the request of the Railroad Administration, to avoid congestion of coal at tidewater, and the resultant embargoes.

The order includes the suspension of price and zone regulations on coke and bituminous coal which, it was announced Jan. 17, would be effective Feb. 1. As the Administration's control of the oil industry already has been suspended with the exception of certain natural gas regulations, the effect of the order of Jan. 31 was said to be that the Fuel Administration's controls are now relaxed to the present limit of safety, pending the proclamation of peace, when the Administration automatically will terminate.

It was pointed out that as the responsibilities of the Fuel Administration under the Lever Act continue as long as a state of war officially exists, any of these suspended regulations may be reinstated or others may be put into effect should occasion arise. An instance of the continuing activities of the Administration was found in its Bureau of Labor, which will function actively during the armistice. Any dispute failing in settlement between the parties at interest must be submitted as heretofore to the Fuel Administration for final disposition without stoppage of work.

The following statement was issued:

By his Executive Order of Aug. 23, 1917, the President adopted as maximum prices for anthracite coal the schedule of prices which had been acquiesced in by the industry while under investigation by the Federal Trade Commission under the so-called "Calder" resolution of the Senate. This involved one price for the railroad controlled coal companies and a price 75c. higher for the individuals. With the exception of a reduction of 60c. a ton in the prices for pea coal made Oct. 1, 1917, and two adjustments to cover increases in miners' wages, the Fuel Administration allowed the prices fixed by the president to stand pending examination of costs such as were made in the case of bituminous coal.

For the purpose of arriving at a fair increase in price to cover the increase in wages recommended by the War Labor Board last October, an examination was made to determine the costs of the various anthracite producing companies. The result of this examination showed that the general increases in the price of materials and labor had raised the cost of mining anthracite to such an extent that many of the companies were not receiving a fair return and that some producers of necessary coal were actually sustaining a loss on the sale of coal at the Government prices, in spite of the two increases allowed on account of advances to labor.

At the time this situation was discovered every indication pointed to an early peace and it was deemed unwise to increase the maximum prices so near the time when, on account of the end of the war, price restrictions would in the natural course of events be lifted entirely.

The foregoing statement is made at this time, when price restrictions are about to be lifted, out of fairness to those companies who have patriotically kept up their production to war needs, even at a cost which resulted in many instances in a loss, not only by the individuals, but also by some of the railroad companies, so that the impression shall not exist that the Government prices of anthracite coal in existence at the time of the lifting of restrictions were prices which the Fuel Administration had fixed on the basis of cost to the operators.

Had the Fuel Administration's active control over maximum prices on anthracite coal been continued, the cost examination above referred to shows that it would have been necessary, on the basis of the present wage scale, to raise these maximum prices possibly as much as 50c. a ton above those last fixed by the Government, in order to prevent financial embarassment and perhaps the closing of companies producing a substantial percentage of the necessary anthracite output.

Such a curtailment of production would eventually result in the demand exceeding the supply to such an extent as to increase the prices much higher than they would be if that supply were continued.

Examiner Reports Unfavorably in Western Kentucky Rate Controversy

A report unfavorable to the contention of the Ohio Valley Coal Operators' Association has been made to the Interstate Commerce Commission in the matter of rates from western Kentucky to various points in the Mississippi Valley and the Southwest. The examiner declares that evidence has not been produced showing that the rates complained of are unreasonable per se. He cites several instances, however, where the removal of prejudicial rates is desirable. The Commission may or may not follow the report made to it by the examiner.

Anthracite Committee of Fuel Administration Goes Out of Existence

The Anthracite Committee of the United States Fuel Administration, which has had direct control over the distribution of anthracite since its appointment last March, has gone out of existence in accord with the general order of Dr. Garfield relinquishing all price and other control over coal and coke. Communications regarding matters formerly handled by this committee should in future be addressed to the United States Fuel Administration, Washington, D. C.

Pooling of Railroad Equipment Resulted in Sufficient Car Supply

A total of 16,500,000 tons of coal was loaded into vessels at Hampton Roads between June 1 and Dec. 20, 1918. This is an increase of 1,500,000 tons in the amount of coal handled during the corresponding period of 1917. The regional director for the Pocahontas district is authority for the foregoing figures. In a report to the Director General of Railroads, he also makes the following statements:

To the common use or pooling of coal-carrying equipment and its distribution by central control and the pooling of coal at tidewater and at Lake Erie ports is attributed a practically uniformly sufficient car supply at coal mines, resulting in increased production.

Consolidation of coal-dumping facilities of the Norfolk & Western, Chesapeake & Ohio, and Virginian railroads at Hampton Roads, Va., together with pooling of coal by interested shippers under direction of the United States Fuel Administration, and shifting of vessels from one pier to another for loading under direction of the United States Shipping Board, made possible handling of a greatly increased coal tonnage for transshipment by water to New England, for bunker purposes, and for the Army and Navy and overseas, and materially lessened the delay to railroad cars awaiting dumping and delay to vessels awaiting berths at piers, under adverse shipping conditions.

During the last six months of this year nearly 400,000 tons of coal was transferred in cars from the rails of the Virginian R.R. after arrival at Norfolk, Va., to the rails of the Norfolk & Western R.R., and dumped over the Norfolk & Western piers, at a time when the facilities of the Virginian were inadequate to dump the coal as fast as it could be transported. This shifting of cars for dumping resulted in accelerated dispatch and was a factor in maintaining a free working supply of cars at the mines for reloading.

By arrangement with the United States Fuel Administration, certain tonnages of low volatile coal needed in the West were drawn more particularly from the Norfolk & Western R.R., and like tonnage turned east from the Chesapeake & Ohio R.R., reducing crosshauling on the Chesapeake & Ohio R.R., through yards where the movement was forcing in excess of facilities for handling.

The Norfolk & Western R.R., Columbus line; Chesapeake Columbus line, were used in common in moving western coal through Columbus and Cincinnati, Ohio, gateways from the mines of the Norfolk & Western and Chesapeake & Ohio, and in handling empties returning to mines through those gateways. This common use, together with the prompt receipt of loads by connections at Columbus and Cincinnati, which, being also operated in common, alternated in moving loads from the Chesapeake & Ohio and Norfolk & Western when offered and as necessary to keep traffic going forward currently, resulted in extraordinarily free movement of western coal traffic in very heavy volume.

Pending improvements on the Virginian R.R., to enable it to handle maximum tonnage of coal from mines for which it served as outlet, that road was relieved of handling traffic moving over its line overhead from connecting roads for destinations beyond the Virginian R.R. and such traffic taken over by the Norfolk & Western and Chesapeake & Ohio railroads.

Double service performed by Chesapeake & Ohio and Virginian railroads to coal mines served jointly by them was discontinued, and individual joint mines assigned to the Virginian or Chesapeake & Ohio respectively for single service, resulting in saving in fuel for engines, time of train and engine crews, and more efficient service.

The regional director for the eastern region lists the following as one of the greatest transportation achievements in his region:

The Lake coal and ore movement was followed vigorously throughout the year, and the volume of shipments offering were handled currently, with the result that there was a total of 29,388,242 tons of coal dumped at Lake ports prior to the close of navigation on the Great Lakes, or 917,963 tons in excess of 1917. The ore movement from the Lake ports for the season totaled 33,726,380 tons, which was 368,000 tons less than 1917; 1,622,000 tons less than 1916, and 6,343,000 tons in excess of 1915. The coal program was completed on Nov. 30, 1918, as compared with Dec. 12 in 1917, and the tonnage handled was the largest on record.

Gathering of Statistics on Coal and Coke May Have to Cease

Unless Congress will approve an appropriation of $40,000, asked by the Geological Survey, the coal industry will not continue to have the advantage of the special statistics which have been compiled by the Fuel Administration on coal and coke production and distribution. Owing to the increase from 5000 to 8000 in the number of coal mines, the Survey's appropriation is inadequate even for its regular coal statistical work. As Congress probably is not acquainted with the value that these statistics are to the coal industry, it is feared that the appropriation will not be allowed. In recommending the appropriation, the Secretary of the Interior said:

This appropriation is intended to provide for the continuance after June 30 next of the statistical work now conducted on an extensive scale by the Fuel Administration in coöperation with the Geological Survey of the Department of the Interior. The collection of the statistics of coal and coke production by the Geological Survey before the creation of the Fuel Administration in August, 1917, was necessarily largely and rapidly expanded to meet the fuel demands of the nation during the industrial crisis, and up to November last the work was on a scale of an annual expenditure of more than $400,000. Since then the demand for some of the classes of inquiries as to stocks of fuel, etc., has changed so that the extent of the work is now being rapidly reduced. Yet experience has shown to both the coal industry and the general public the real need of official information on the subject of coal production and distribution in the form of current statistics frequently collected and promptly issued by the Government, and it is the expressed desire of the Fuel Administrator that provision be made for the continuation of work on at least the reduced scale provided in the appropriation here recommended.

I regard as conservative the annual expenditure of $40,000 for thus keeping the public authoritatively informed as to the working condition of this nation-wide industry which represents a capital investment of more than one billion dollars for the bituminous coal mines alone, which altogether employs an industrial army of three-quarters of a million men, which furnishes not only the motive power for the railroads but one-third of the freight carried, and which represents the constantly changing development of the nation's largest mineral resource.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The termination of the world war seems from the indications in the newspapers to be drawing close. With it comes the end of our labor contracts. The fourth clause of the Washington agreement says: "Subject to the next biennial convention of the United Mine Workers of America, the Mine Workers' representatives agree that the present contract be extended during the continuation of the war and not to exceed two years from Apr. 1, 1918." So much for the bituminous region. In the anthracite region the contract will end at the same time.

Under those circumstances it seems the height of imprudence for the business concerns to reduce their stocks by using more bituminous coal than they buy. The Chicago & Alton R.R. in Illinois sees the matter in the right light. The Alton road on Jan. 16 gave orders that 50,000 tons of coal be stocked along certain of its abandoned tracks. The continued shortage of work is, however, showing the mine worker how the land really lies, and while some are only angered by the slack work and some are prone to say it must be met by increased pay for working days as a balance for those that are idle, some men are convinced that the mine worker will get all he can expect if he keeps his wages at the present level.

Wage Rate Already Graduated for Slow Time

In fact he should be quite content with that concession; for irregularity of employment is becoming quite general, and the mine worker must expect a little of it. Moreover, he may remember that his recent increase in pay was largely granted to satisfy him for the short time he was permitted to work. When he worked half time, he demanded enough to give him full-time pay. Almost immediately thereafter he got full time and his pay was not scaled back. Now he works short time he wants increased pay as a compensation for his irregular work. Like a man on an old fashioned mine engine he shifts from foot to foot, always rising with the step which is for the moment ascending. Now the short-time rod lifts him up. Then it is the steady-work rod boosts him a few feet. Again he chooses the short-time rod, seeing it is likely to help him upward. It would be all right if he were the only person in the world, but this constant climbing is at the cost of the working-man consumer.

Heidelbergers Will Submit Minimum Wage Demand

The strike at the Heidelberg collieries, Nos. 1 and 2, of the Lehigh Valley Coal Co. located at Dupont, Penn., came to an end on the evening of Jan. 27. The men are going to confer with the company through a committee. District President Yannis (District No. 1) advised the men to return to work and let the matter be settled in the appointed way. Further details about this strike which commenced Jan. 18 can be found on page 238 of this present volume. On Jan. 27, 1200 mine workers at Pine Colliery of the Delaware, Lackawanna & Western R.R. Co. Coal Department had a button strike.

United Mine Workers' officials say that at some of the collieries there has been trouble because men who filled two associated jobs during the war are no longer willing to do so, now that the scarcity of employees is decreased. Though one man could easily fill two positions they demand now that two men shall be employed.

In the Lehigh region the United Mine Workers of America have lost strength during the war. Before the war, there were 17,000 members and now only 13,000; the 4000 men who have left are said to be accounted for by the military draft and by migrations to munitions works.

The mine workers of the anthracite region are establishing coöperative stores such as are common in Illinois and Ohio. The Shenandoah mine workers appear to be taking a large part in starting the coöperative movement. On Jan. 29 a wholesale and retail store will be opened and more will follow later.

Anthracite mine workers have so anxiously sought wage increases and have used such unfortunate ways of securing them during the war that it is strange that they should begrudge meeting the increases in expense of the Lehigh Traction Co. of Hazleton by the payment of increased car fares. The mere penny a ride demanded did not hurt the mine workers' pocketbook, and it certainly was a measure of justice. At least, the Public Service Commission took that point of view and dismissed the complaints of two narrow-minded, reactionary locals which could not see that right was right regardless who the claimant might be that sought redress.

Russians Want Their War-Work Money Back

In Ellsworth, Penn., it appears that a demobilized soldier who had secured a job with the Ellsworth Collieries Co. spread the report that the United War Work Fund was merely a fraudulent scheme for depriving the men of their money. The Ellsworth men, for the most part, are intelligent workmen, but there are a large number of Russians among them, and they believed all that was told them. A meeting was held by K. K. McClure of the Department of Justice, and 300 Russians by their cries broke up the assembly.

According to Government officials each miner agreed to give $4.75 to the fund. The company collected in all $7596.88, but gave no receipts for the money. This also was thought by the suspicious to be evidence of irregularity. It is said that the money was put in the bank to the credit of the Ellsworth company.

Union organizer Garvin tried hard to allay the agitation which he firmly believes to be in every way unjustified, but the Russians are not to be convinced by arguments when uttered in a language that they do not understand. Moreover, they seem bent on dragging Ellsworth down to the level of the towns in the Dombrova basin of Russia. The Ellsworth company is truly worthy of condolence. It has done more for its men than almost any other company in the United States. For many years it has extended a friendly hand to the union.

It is only just to the union to say that it has reciprocated, but some of the Ellsworth foreign mine workers—the old Believers of Russia—sometimes seem almost beyond the compulsions of kindliness and generosity. At other times the work of the company among these people seems to be meeting with great success, though nothing like that attained with the Slavs and Italians who seem more amenable to sympathetic guidance and who learn enough English to absorb American ideals. The company is willing to return the money collected to anyone who makes a demand for it.

Would Legislate for Weighing of All Coal

District No. 29 of the United Mine Workers has passed a resolution condemning the committee on Mines and Mining of the House of Delegates in West Virginia for its adverse report on a measure requiring all mines at which ten or more men were employed to pay the miners by weight and which also required that scales be installed and maintained at such mines. The records of the House do not show that the bill has been voted upon yet. While no definite figures are obtainable it is not regarded as probable that there are more than 50 per cent. of the mines of the state of West Virginia equipped with scales.

SAFETY LETTER

from Consolidated Coal Co.
to its Safety Committees

Would you stand in front of a cannon and deliberately fire it off? Surely not. Then why use a short shooting cable when you fire off a shot?

On October 24, Fred, who had been employed in mines for twenty years, put off a rock shot of carbonite with a short shooting cable. In consequence he had to stand in the direct path of the flying rock and was hit by a piece which was flying like a cannon ball. His right side, arm and back were so badly bruised he could not go back to work for over a month.

Pieces of rock and coal don't always fly like this when a shot is put off but they are liable to do so at any time. Get well clear of the flying coal when you put off a shot and keep your shooting cable long enough to be able to do this. Cable costs so little, and accidents cost so much, so why take the risk?

EDITORIALS

A Million Years of Maturing or Only a Few Hours of Toasting

SOME DAY we may wonder whether it was worth while chasing coal 2000 or 3000 ft. below the ground, with trouble from bumps and squeezes, expensive hauls, steep dips, deep shafts, discomfort, danger and gas and what not, when by some contriving, the nature of which is perhaps not wholly clear up to the present, we could have converted lignite into coal or acceptable coke by a few hours of judicious toasting and could have secured a large quantity of byproducts in the bargain. We cannot perform these wonders yet, but we surely will be able to do so later. Then we shall be able to strip the top off an extensive lignite bed and toast it into good coal, the counterpart of anthracite. The byproducts and the saving in freight rate will pay us royally for our pains, and we shall be saved all the wastes, expenses and dangers of deep mining. The lignites are for the most part found under light cover. Of course, they are in many, many instances only minable by underground methods, and in some cases they may be extremely deep. To such profundities they will not soon be followed, but they may be worked in shallow depths abundantly if only the toasting problem can be satisfactorily solved.

Father Time: After 838,475 years of my patient effort, the peat has at length turned black!

It is interesting to notice the condition in Western Canada. Only 6.71 per cent. of its actual reserves of coal are semi-anthracite or bituminous. The other 93.29 per cent. is lignite or lignitic (that is, sub-bituminous). The higher-grade coals are in the mountains and are rare. The lignites are on the lower levels and are well distributed. If by toasting them we can get the service of high-grade coal from them, we may find that Saskatchewan and eastern Alberta will be even greater rivals of the Canadian Rocky Mountain region than they are at present.

Even now these regions are healthy rivals. Our readers, we feel sure, will be surprised to learn from the pen of James White that in 1917 the lignite production of Alberta was greater than the combined bituminous and semi-anthracite production of the province, for the lignite mines produced 51.3 per cent. of the whole coal output of Alberta.

We look upon anthracite today as the super-coal, the triumph of long ages of toasting. Some day we may change our point of view. Anthracite will be regarded as a fuel from which time and heat have leached the most valuable of byproducts, leaving a barren substance, suitable only for burning. Meanwhile soft-coal lignite, and even peat, the Cinderellas of the fossil fuel world, will be regarded as substances of greater value. Instead of saying "only lignite," we may say "only anthracite," regarding the latter as the more senile, and less useful, product of the mineral world. The very scarcity of anthracite is making such a point of view likely, for we shall soon be obliged to make anthracite substitutes in large quantity. We shall carry the toasting to the exact degree we think advisable, and incidentally we shall learn how to derive all manner of profit from that partial distillation. If highly mineralized anthracite had been more general, better distributed and in larger quantity, it would have stood in the way of the development of the coal-distilling industry; in fact it might have prevented the manufacture of coke of all kinds, for anthracite is an excellent smelting fuel.

But anthracite, being remote from the points where it was needed, and being minable for the most part with difficulty, has permitted the development of the coke industry; and it will doubtless have also to permit the development of the toasted-coal industry. After all, the world has the virtues of its defects. If we had all the mineral wealth we desired along certain lines, we might fail to develop other minerals, such as soft coal and lignite, which may hold even greater possibilities before us. We may find in them not only things "just as good," but better.

Mudding Coal at St. Eloy, France

AN ARTICLE in the present issue describes the manner in which the badly crumpled bituminous coals of St. Eloy are filled with mud as a means of extinguishing fires. The reader will assume, and assume rightly, that a bed uncrumpled and not creviced would not take so kindly as the St. Eloy coal does to this process of fire extinction.

Apart from this crumpling, French coal seems to have a quality of its own. We could imagine a slow-burning

anthracite thus readily extinguished, but it is hard to conceive of a coal having 35 to 40 per cent. of volatile matter submitting thus tamely to such a slow and incomplete process of sealing. It shows that there is something yet for us to learn about coals and their ways.

Perhaps this coal tends to give out carbon dioxide rather than methane. Some of the French coals have that peculiarity. It is evident that a coal which at an extremely low heat gives off non-combustible gas will be easily extinguished, whereas one which gives off a combustible gas will refuse to succumb to treatment. The question comes whether slack would not be better than washery waste or ashes, for coal thus thoroughly impregnated with infinitesimal impurities must be almost ruined for market purposes. In places in the St. Eloy district the seams almost combine and reach together a thickness of 86 feet.

Of all times in history, the present is the one time when the mine official must saturate himself with sound economic doctrine. He must remember that the fundamental laws of economics are quite as important today as are the laws of ventilation, haulage or hoisting.

Byproducts of Labor-Union Activity

LABOR unions have grown considerably during the war. They have gained more and more the ability to get what they demand, subject only to economic law. Workers in one industry, say coal mining for instance, press for an increase. They get it, and the artisans in other industries pay it. Immediately the other industries become envious of the good luck of the men in the coal mines and later they begin to feel the effect of the appreciation in the monetary value of the coal they purchase. So they in turn demand increases.

The situation resembles nothing more closely than an old pantomime stunt, in which Clown has his sausages stolen by Harlequin, and Harlequin no sooner rejoices in his pelf than he is robbed by Columbine. Then Pantaloon and Scaramouch rob and are robbed in turn. The humor of it never failed to bring down the house. Just in the same way the workers of various industries pick the pockets of one another. By demanding higher wages they cause a continued increase in the cost of living, in which all lose what they have gained.

But this continued increase is, on the whole, favorable to business. Under its influence prices of goods do not decline, they rise. In consequence it is safer to buy goods or to construct buildings than to retain money. Hence, trade is steadily encouraged, and waiting for better times is an unprofitable undertaking.

Unjust as is inflation in many respects, the public thrives on it. Inflation is often one of the byproducts of extensive labor unionism. It is a splendid stimulant, but it must always be remembered that it should be used with caution. The worst Russian "jag" has been inflation, and not vodka. In that vast region everyone wants to buy and no one to sell. We want a little of the keenness to buy right here, while Russia would greatly like our keenness to sell. A little inflation is like a cup of coffee—a good beverage which, if taken moderately, will clear our minds of the inertia of the night.

Did Labor Profiteer During the War?

REPRESENTATIVE HUDDLESTON, of Alabama, on Jan. 21 addressed the House of Representatives in defense of labor. He declared that labor did not profiteer during the war, and with a delightful indifference to the fact that many men's wages rose immensely in 1918, submitted a table showing only the increases between December, 1914, and December, 1917. The table he quoted also left out all account of the increases of many classes of workingmen, notably the miners. Yet there are a number of these in Huddleston's district.

But taking Representative Huddleston's table just as it is, one cannot fail to conclude that certain laboring men did most grievously profiteer. Some gained 65 per cent. increases and others only 6 and 7 per cent. Some which the table does not mention probably got no increased wage. We are asked to absolve all labor because the average increases in the pay of labor did not exceed the increases in cost of living. But the argument seems to be that some men had less buying power at the end of 1917 and others had more. So evidently some workingmen did profiteer.

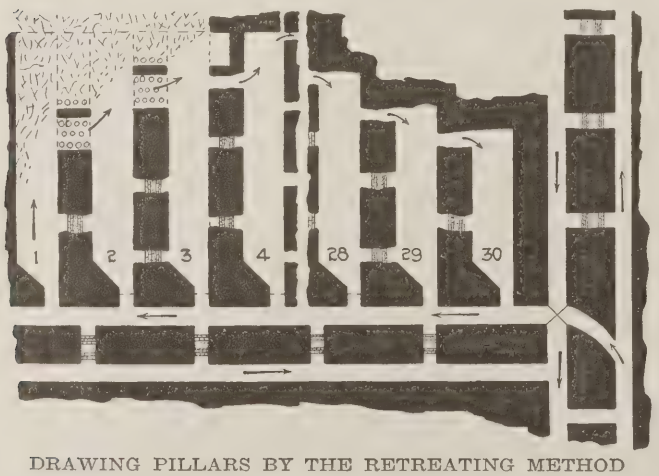
As a matter of fact labor as a whole can never profiteer. The wage of labor can never be any more than labor produces. There is therefore a limit to the real payment of labor, and that limit is set by production. If production increases, then the real payment of labor can be increased, and that without profiteering. If the production does not increase every increase on the face value of wages is either not a real increase of wages or it is profiteering. The increase is obtained at the expense of other workingmen. Every increase of wage puts up the cost of living. Every change in the rate of pay of any one class of operatives decreases the real earnings of every other class. The high wage of the sheet-metal workers, the loftsmen and electricians, to quote Huddleston's misleading table, reduced the real wages of the bricklayers and others.

By lifting themselves they dragged other workingmen down. Labor as a whole cannot profiteer. Certain trades can; individuals also can; but speaking in general, we cannot one and all profiteer on one another. Labor cannot profiteer as a whole any more than a man can raise himself by tugging on his shoulder straps. If labor by striking could increase its real returns without reducing thereby the returns of other labor, the strike would be so beneficial to the human race that labor agitators would deserve statues in the public squares. As it is, strikes are but attempts to exploit the workers in all other industries than the one which is striking, or are attempts to rectify the conditions of some industry at the expense of others.

The profiteering of labor cannot be disproved or excused by showing that labor as a whole did not profit by it. The profiteering was only the more to be condemned because all did not share in it; and, in fact, had other workingmen not been made the poorer by it, it would not have been profiteering. But it must be conceded that part of the increase was not profiteering at all, especially in 1917. It was a contribution to the workingman to induce him to leave his home and meet the cost of entering a new and often temporary industry in a new and often makeshift town. He was entitled to payment for it, no matter who had to provide it.

DISCUSSION BY READERS

Drawing Pillars in Machine Mining



Letter No. 1—The inquiry of "Operator," regarding the drawing of ribs by machines, which appeared in *Coal Age*, Jan. 2, p. 32, was particularly interesting to me, inasmuch as the conditions with respect to the roof and height of coal are similar to those in our mines. We are using three types of machines, one of which is the same Sullivan shortwall machine stated as being employed by Operator.

The width of the rooms being given as 27 ft., I assume they are driven on 40-ft. centers, leaving pillars 12 or 13 ft. wide to be drawn. I would suggest, here, that better results can be obtained and greater safety secured by driving the rooms narrower, say 18 or 20 ft. wide, which would make the width of pillar 20 or 22 feet.

A machine will remove the supporting coal at the rate of about 15 to 18 sq.ft. per min., which is much faster than can possibly be done when using a pick. Moreover, in machine work there is not the same chance to set timbers for the support of the roof as in pick work.

In drawing back ribs, by machines, the cross-section of a 12-ft. pillar does not afford sufficient strength to break the rock, under 200 ft. of cover, when the first cut has been made with the machine. The consequence is that the weight of the roof rides over, crushing the narrow pillars and developing a squeeze or creep in the workings.

In the accompanying figure, I have attempted to show the general plan that we have adopted in our mine and

DRAWING PILLARS BY THE RETREATING METHOD

which has been found to work succesfully when drawing back the ribs by machines. The figure shows a section of the workings, on a pair of crossheadings driven to the left of the main entries. These headings have reached the boundary line and are being worked out on the retreating plan. The rooms have been started at the inby end and driven to the limit, in regular order.

As the limit is reached in each room, the work of drawing back the ribs is commenced by cutting through the rib in No. 1 room with the machine, and setting posts for the support of the roof, as the work progresses. When the pillar has been cut back 18 ft. from the face, a stump 4 or 6 ft. in width is left, and another 18-ft. cut is made through the pillar. The stump left is then drawn with picks and the timbers pulled with a chain-puller so as to cause a fall of roof. At times, a small stick of dynamite is used to destroy a post that cannot be pulled with safety.

Essentials in Pillar Work

An important feature in the work of drawing pillars is to keep the ends of the pillars in line. This gives a good line of fracture for breaking the roof, which relieves the pressure on the pillars and greatly assists the mining of the coal.

In order to remove ribs successfully, all the coal must be taken out, and if this is done conscientiously there will be no trouble. I have known of instances where thick stumps have been left in rather than pay pick prices for removing them. The result has proved, however, that this is a grave mistake, as success can only be achieved when all the coal and timbers are removed.

In other cases, a too sparing use of timber has caused trouble. It has the effect of throwing an undue weight on the pillars, which makes the coal difficult to mine and induces squeeze or creep. Enough timber must be used to hold the top perfectly sound, until the time comes to make a fall, when all timber should be removed and none left standing in the waste.

In closing, let me say that it is my belief that "Operator" will have no trouble in extracting all of his ribs with safety and economy, by adopting the methods I have suggested. This opinion is strengthened by the fact that we are working the same machines under, I might say, the same conditions. In case a mine is generating gas and locked safety lamps are required, a flameproof machine, such as the CE7 Jeffrey, Goodman, or other type, should be employed. D. F. M.

Meadow Lands, Penn.

Letter No. 2—In reply to "Operator," who asks for the best method of drawing pillars in machine mining, *Coal Age*, Jan. 2, p. 32, let me say that he has omitted one of the most essential things regarding his question; namely, the thickness of the pillars between adjoining rooms.

When mining under a sandstone roof, there is always great danger of bringing on a creep when drawing back pillars, either in pick or machine mining. Comparatively small pillars may be strong enough to bear the overburden, in driving the rooms to their limit or, as we say, in the "first working." But, when the work of taking out the pillars is started, the roof pressure will generally prove too great and the ends of the pillars will be crushed to such an extent that it becomes practically impossible to recover all the coal,

or even enough of the pillar coal to bring about a good roof fall and relieve the pressure.

At times where the coal is hard and the bottom soft, the latter will heave under the increased weight resting on the pillars. When that takes place, the pillars are forced down into the bottom, and it is impossible to use the machine or even to mine the coal remaining in the pillars.

Assuming, however, in the case presented that there is a good thickness of pillar, sufficient to bear the weight of the overburden until enough of the pillar coal can be taken out to bring about a good roof fall, it should be possible to recover all the pillar coal by adopting a proper method of working the seam. For instance, not a room should be turned, until the butt headings have reached their limit and it is possible to work out the coal on the retreating system.

Drawing Pillars in Five Rooms at a Time

Now, commencing at the inby end of the heading, five rooms should be started and driven on 60-ft. centers. The rooms should be widened to 24 ft., which will leave 36-ft. pillars between them. They should be driven to a distance of not less than 275 ft. and more, if it is possible to extend them further with safety and economy.

When these five rooms have reached their limit, the work of drawing back the pillars between them is commenced at the face of the last room but one on the heading. At this point, a crosscut is driven through the pillar, separating this room from the last one. The crosscut should be driven about the same width as the rooms.

With a sandstone roof, such as is here mentioned, it will be possible for the machine to make a cut clear across the face or end of the pillar. All props should be taken out except a good strong breakrow. This breakrow, of course, must be strong enough to protect the machine. As the work advances, and the space standing behind the breakrow becomes so great that it does not appear safe to make another cut in the end of the pillar, a second crosscut should be started and driven the same width as before, leaving a 6-ft. stump between the end of the pillar and the rib of the crosscut. When this crosscut has been driven through the pillar, it will often be possible to cut out all the stump with the machine, except 3 or 4 ft. on each end, which must be taken out with a pick.

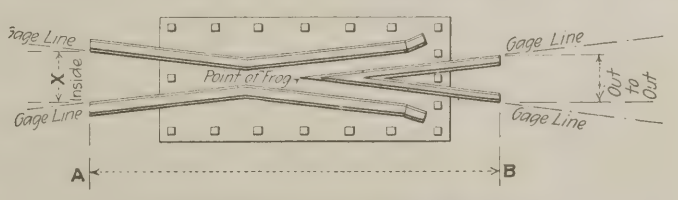
Pillars and Rooms Worked on 45-Deg. Angle

For the success of the operation, it is important not to start to cut through the second pillar, until the first cut has been taken on the first pillar. The same plan must be followed in respect to each of the other pillars, which will make the line of the pillar work assume an angle of about 45 deg. with the heading and the last pillar will be about commencing when the first pillar is finishing.

At this stage of the work, five more rooms should be started in turn, keeping the face in each a few cuts in advance of that in the room next adjoining, so that the faces of these rooms will make about the same angle of 45 deg. with the heading, as is the case with the pillars that are being drawn back. It will be observed that the 45-deg. line marking the faces of the rooms will be opposed or at right angles to the 45-deg. line marking the ends of the pillars. When the first pillar is drawn back to the mouth of that room, the men drawing the pillar continue, by taking out the stump on the heading and the entry pillar, keeping the same 45-deg. line as before.

My understanding of the case presented by "Operator" is that he has a lot of pillars standing. Even in that case, the work of drawing the pillars should begin with the last one on the heading. If these pillars are any less than 20 ft. in width, I would start about six of them, putting in as many men as possible and working day and night, doing everything possible to induce a break in the roof. It is of utmost importance to leave no stumps remaining, but all must be removed, or blown out if it is necessary to lose the coal.

On the other hand, if the pillars are ample, the work of removing them should be started on the last pillar and the same plan followed that I have just described, keeping the ends of the pillars on a line of about 45 deg. with the heading. In removing pillars of a good thickness with machines, there should be no trouble to recover all the coal. But, if the pillars are not thick enough, there is bound to be trouble whatever method is employed for their removal.



Room stumps should never be less than 50 ft. in thickness; or, when working with a single entry, a 50-ft. barrier pillar should be left to protect the entry. Never let a cutter cut out an entire stump, as the settlement of the coal will have a tendency to bind the cutter-bar and hold it fast. Always leave a small stump for the protection of the men and the machine.

McIntyre, Penn. THOMAS HOGARTH.

Mine-Track Switches

Letter No. 1—Referring to the inquiries, *Coal Age*, Nov. 21, p. 961, and Dec. 26, p. 1179, kindly permit me to draw attention to one or two points that should be emphasized, where trackmen often make an error in measuring a frog. When measuring the spread of the rails, the measurements must always be taken between the gage lines.

In a standard-gage frog, such as is used on surface railways, the gage lines are on the inside of the rails

A STANDARD-GAGE RAILWAY FROG

that form the wing rails of the frog, while at the other end they are on the outside of the rails forming the V of the frog. I might call one the "X measurement" and the other the "V measurement," the former being taken on the inside of the rails and the latter on the outside, as shown in the accompanying figure.

Let me say, here, that 95 per cent. of coal-mine frogs, however, consist of the V part only and do not include the wing rails that form the X section of a standard frog. Hence, the number of an ordinary V, or mine frog, is found by dividing the length of the V by the

spread, as measured out to out of the rails. For example, if the V is 24 in. long and the spread 8 in., the frog number is 24 ÷ 8 = 3, this being a No. 3 frog.

Speaking of the radius of a switch, let me say that few switches, in mines, are laid to any exact radius. In mine work, the radius of curvature of the lead rail is of use chiefly for aiding the calculations of the proper length of that rail, and other dimensions. In actual practice, the frog must be laid in a position, on the main track, to suit the opening at the room or heading. After passing the frog, the curve may follow any radius best suited to the conditions.

Also, conditions in mines regarding the speed and the pulling and pushing of trains, and the effect of the rope, in rope haulage, make it impracticable to estimate the proper elevation of the outer rail by the usual methods. Practical trackmen rarely exceed ⅛ of the gage, for the necessary elevation of the outer rail on a curve.

Wheeling, W. Va. R. Z. VIRGIN.

Reducing Ventilation at Firing Time

Letter No. 3—After reading the letter of John Verner, *Coal Age*, Nov. 28, p. 1000, in which he advocates reducing the circulation of air before firing shots in a nongaseous mine, I have since read Technical Paper 190 issued by the Federal Bureau of Mines, to which he has referred. The authors of that paper condemn the practice advocated by Mr. Verner, basing their conclusions on experiments made by them to determine the effect of a reduced circulation of air on the firing of shots in mines.

Taking these experiments as demonstrating the fact that such a practice is highly dangerous, I cannot see how shotfirers still cling to that method. There have been repeated explosions, and shotfirers have been killed, simply because they relied on their own experience and would not accept of what was told them. As mine statistics rarely cover cases of such accidents, except where five or more persons are killed, the many deaths of this nature that occur escape public notice.

CHIEF DANGER IN RAPID SUCCESSION OF SHOTS

As I understand it, the argument advanced in favor of this practice, emphasizes more the danger of an increased draft of air causing an explosion, rather than the firing of shots in rapid succession. To my mind, the latter condition is the more dangerous of the two.

On pages 33 and 34 of that paper it is stated that the authors kept a record of the time required to fire the shots in a certain mine, during 11 days. Two shotfirers were employed and an average of 160 shots were fired each night, the time of firing ranging from 1 hr. 27 min. to 3 hr. 45 min., although it required 30 min. for the shotfirers to reach their work after entering the mine, and the same time to reach the shaft bottom when their work was ended.

These results show a continuous firing of more than one shot a minute, in that mine, and make it certain that the shotfirers did not pause to ascertain whether any brattice had been blown down or other damage done after a shot was fired. They, undoubtedly kept on the run from one place to another.

Let me illustrate this condition, by supposing that 3 hr. is the time allowed for the firing of shots in a mine generating a very small amount of methane, say ¼ per cent., which would not be detected on a lamp. Now, if the fan is shut down before firing is commenced the air at the working face of each room will be still when the shots are fired. If gas comes from the roof or the top of the coal, it will be stratified in a thin layer and form, in a short time, a dangerous condition for firing shots.

The tables on page 26 of the same paper show that tests made in one entry, at the roof, revealed an increase from 0.29 to 2.84 per cent. of gas. In another entry the increase was from 2.52 to 3.72 in 2½ hr. The tests made in the last open crosscut, however, showed only a negligible increase in gas, making it appear that the gas accumulated at the roof in the places where it was generated, and that the air current was not strong enough to sweep it away.

Attention was drawn to the fact that, in practically all of the tests made, the oxygen content of the mine air was normal. The argument that the slowing down of the fan reduces the amount of oxygen in the mine is thus proved a fallacy. The danger from the cold air, in winter, entering a mine arises from its increase in temperature while circulating through the mine airways. This makes it possible for the air to absorb a large amount of moisture and dry out the mine, rendering it more dusty and dangerous. Let me suggest, here, that when the fan is stopped there is a fall of pressure, which may cause gas to issue from abandoned places in the mine.

URGES THAT FIREBOSSES TAKE MORE TIME

In closing, let me urge that more time be given for firing shots, and that the shotfirer should fire these in regular order, proceeding against the air. To fire 160 shots should require 5 hr., which would give ample time for the examination of each working place.

As showing the carelessness of many men, I am reminded of an incident that occurred when I was working in the Hart-Williams mine, in Illinois, Franklin County. We were timbering a pair of entries a little distance from the mouth and another gang was cleaning falls nearer the face. A certain driver had the habit of always setting open the door on the entry between the two headings, while he was waiting for a car to be loaded.

On one occasion, I shut this door, whereupon he came back and opened it and sat down against it. I was advised by my fellow workers not to make any trouble, but one can imagine my thoughts, being accustomed to work with safety lamps, where such a practice would mean danger. To my mind, ventilation is an important factor in mine safety. I want to say, in closing, that I have more faith in tests and experiments than in beliefs and theories. GASTON F. LIBIEZ.

Peru, Ill.

Letter No. 4—Whatever can be said in favor of this proposed practice in mines not generating gas, the principle cannot be applied to Pennsylvania mines where the danger of gas is almost always present.

The Pennsylvania mine law is very specific in this regard, and it can be said with truth if the firebosses

in those mines lived up strictly to the requirements of the law, there would not be much coal loaded the next day. In the fireboss' book would be found too many entries made such as "too much gas present," giving that as a reason for not shooting the coal.

Again, the Pennsylvania law demands the sprinkling of each place before firing shots, wherever gas can be detected by an approved safety lamp. While it is true that some of the most gassy mines, in this state, are the wettest and there is no need of sprinkling, it is still necessary to keep bratticemen busy and the fireboss must always make careful tests for gas, before shots can be fired. Under such conditions as these, the question of reducing the ventilation in the mine, at the time of firing shots, is an idle one. No superintendent, foreman or fireboss, would consider the proposition one moment.

I recall a miner who was working at the face of a room where a small amount of gas was generating, although not sufficient but that open lights were used. The man gave warning that he was going to fire, which he did, with the result that the gas coming from the coal fired all over the face. The funny part, however, was the man lost his head and dashed from room to room, knocking out the men's lights from their caps.

My advice is, keep a healthy circulation going, as much for the shotfirer as for the miner that his work may be done safely. R. W. LIGHTBURN.

Perryopolis, Penn.

Protecting a Mine Opening

Letter No. 1—It occurred to me when reading the short article of Raph W. Mayer, entitled "Unique Mine Portal," *Coal Age*, Nov. 14, p. 909, that it would have been possible to have secured far better results, in the case he mentions, by adopting some plan that would have permitted the mine to be operated continuously.

In his article, Mr. Mayer states that the mine opening is located in a hill that rises abruptly from the Monongahela River. The narrow bench, on the river, bank, is occupied by the double track of the Pennsylvania Railroad and, to avoid hauling the coal across the track, it was necessary to drive a tunnel, from the river, underneath the railroad.

The mouth of the tunnel, he states, was lined with heavy concrete walls extending back to the coal. As the opening was below the high-water mark of the river, it was necessary to close the mine during high water, by constructing a water-tight door, which was bolted to the face of the concrete walls of the tunnel and tightly sealed. In my opinion, the necessity of putting up and taking down this door, at each time of high water, would be a decided nuisance.

It appears to me that, providing the mining of this coal would warrant the outlay, it would have been far better to have extended the concrete walls 8 or 10 ft. further and sealed the inclosure against the inrush of water by an end wall. These walls should, of course, be carried up above high-water mark and a small tipple erected on this foundation. This would allow a balance hoist to be used for lifting the coal to a sufficient height to permit it to gravitate to the point of loading; or it could be loaded at once into the barges on the river. Such an arrangement would allow the mine to be worked continuously and would be much safer and less liable to inundation from a sudden and unexpected rise of the river. M. STAFFORD.

Chase River, Vancouver Island, B. C., Canada.

Perplexities of Mine Foremen

Letter No. 8—Having had a few years' experience as a mine foreman, and knowing some of the perplexities that he meets in his work, I would like to be permitted to cite one or two instances with which all mine foremen must contend, although these can hardly be called perplexities; they are simply troubles that a foreman must expect.

The mine of which I was foreman had no superintendent and, as a result, when things went wrong I was the one to suffer. We were working a 10-ft. seam of coal that had developed a shale-rock parting about 4 ft. from the bottom of the seam. In order to clean the coal, I put on six rock pickers at the tipple, besides employing a rock inspector, whose duty it was to see that every car that was shipped contained no rock.

Notwithstanding these precautions, however, it would occasionally happen that a car was shipped that contained a little rock and be refused at its destination. Of course, on such occasions, I would receive a personal letter from the head office, calling my attention to the fact in terms that were not fitted to put me in a good humor.

Another source of trouble was poor equipment. We were using steel cars, but had hardly enough of these to keep the mine running to its full capacity. When a wreck occurred, as it would occasionally even though we took every precaution to avoid it, one or more of the cars would be badly crippled, which necessitated such cars being sent to the shop where they would be out of service, perhaps from two to four weeks. To repair these cars, they had to be taken apart by hand, the plates straightened, and again put together by hand, as there was no machinery for performing that work.

BAD EQUIPMENT AND LABOR TROUBLES

But, one of my real perplexities came when the general manager sent me a hoist, if I could call it by that name. It was equipped with a 10-hp. motor and had a drum only 6 in. in diameter. With this hoist, he expected me to develop the main and back slopes, which had a grade of 6 per cent. against the loads. Can anyone suggest how this was to be done?

Not an infrequent source of annoyance was due to the fact that most of the men employed in the mine were Greek miners, whose knowledge of coal mining was limited. Their complaints were many. One day a miner came to me and said, "Well, boss, I no can work my place any more; too much bad top." I said, "All right, I will come up and see your place." Reaching there, I found his top a little bad, but an experienced miner would have fixed it and said nothing. I put up a post and crossbar for him and he went to work again and is there still.

On another occasion, I put two Greek miners to cutting a place through to another room, so as to shorten the haul. They fooled around three days, and then came to me and said, "We no can make nothing in that place;

coal too hard; too much money for powder." I said, "All right," and gave them a change. I then put two Americans to work in the same place and they made $315 clear of expense, the first full month they worked the place.

It was my misfortune to hire a young fellow as a motor nipper, but whom I found, later, to my sorrow, was a pro-German. The first two days he worked fine; the third day be caused a slight wreck, and the fourth day a larger one that stopped the mine all day. I wanted to have the man arrested, but the manager told me to give him his time and tell him to get out of town as quickly as possible, which I did.

In a machine mine, the foreman is always confronted with the possibility of a machine breaking down when cutting the coal at night. Then, if there is no mechanic or electrician around, the machineman goes home and there is no more coal cut that night. The next morning the mine foreman goes to the mine only to find the men complaining that their coal has not been cut.

Notwithstanding this scarcely avoidable occurrence, the management expect the foreman to keep the mine running. If the day's tonnage falls short, the foreman gets another letter that does not add to his pleasantness. But the foreman must maintain his equilibrium, under these trying circumstances, and do his best to keep his temper, which is one of the important assets of a good foreman.

PATIENCE.

———, Utah.

Letter No. 9—The case of the miner who complained to his foreman that the machinerunner had left several inches of bottom coal in his place, as described in a foreman's letter on this subject, *Coal Age*, Oct. 24, p. 793, has attracted some comment. In most respects, I agree with the Homer City miner, whose letter appears in the issue of Dec. 26, p. 1176, and who gives good advice.

In the first place, a mine foreman is responsible for some of his own troubles, which may come from not using proper discipline at the right time. A machinerunner has no right to be careless in cutting a man's coal, and the foreman should be particular to train his men in this regard, and see that each man's place is properly cut. Perhaps more bottom coal was left in this man's place than was necessary and, if so, the man was right in complaining to the foreman. But, assuming that the machinerunner was a member of the same organization as the miner, they were brothers, and one brother would not care to wrong the other or do so intentionally.

The Case Referred to the Mine Committee

The matter, in this case, being referred to the mine committee, it would seem that their duty was to call each of these men to meet them and to listen to their statements so that they, as a committee, could arrive at a proper judgment. Trouble often comes from a lack of proper understanding between the parties. It is not good policy for either a foreman or the mine committee to be obstinate. Right is sure to win.

Too often men expect too much of the mine foreman, especially if he is what they call "easy." Such a foreman will often make a concession rather than have trouble with his men. This foreman may have been justified in offering the miner extra pay for cutting out the coal that had been left; but, in doing so, there is always danger of establishing a precedent that will compel him to do the same thing again. Let me cite an instance where that occurred.

At a certain mine, the development was not sufficient to supply the demand for coal. As a consequence, men were waiting for places. In order to expedite the work, the foreman offered the entrymen 25c. a yard extra because rooms had to be turned as quickly as the entry was advanced, and this made trouble for the men driving the entries. The foreman promised that the extra pay would be continued as long as the conditions continued.

Not long after, however, there was a change in foremen, at the mine. The new man remained only six or seven months and a third man came to take his place. The company was still paying the extra yardage, although the conditions that required this had ceased. A little later, the office asked for the reason why the price paid for yardage was 25c. higher at this mine than at any of the others, and told the foreman he must go back to the old price.

Unfair and Arbitrary Ruling of Committee

When this decision was announced to the men, they at once took up the matter at their regular meeting, and the mine committee was instructed to notify the officials that there would be no more work done, unless the men were paid the same price as before. They admitted that the conditions that required the extra pay no longer existed, but claimed that custom makes a law and that the price was not changed at the time the conditions ceased. Probably that was owing to the foreman not wishing to do anything that would cause trouble.

It has been suggested that a miner is justified in expecting his share of the profits from the increased demand for coal. In my estimation, miners are receiving their just dues. They forget that coal companies have been put to extra expense in order to produce a larger tonnage with fewer men. New equipment and material have been required that were not needed under the old conditions. At the same time, the miner's pay has been advanced from $3.60 to $5 per day.

It is only right to ask what have the miners done in return for the advance made them. It must be admitted that a large majority of our miners have worked fewer days owing to their necessities being relieved by the increased pay that they received. There were some who would lay off to visit another mine where they had been told the men make more money. Eager to make the same, some have given up their places and gone to other mines, only to find that they have been wrongly informed and have returned to their old places, all of which means loss of time. Others not wishing to acknowledge their mistake, have taken up other work and will never go back to the place they were foolish enough to quit.

The increased price paid for digging coal has made it harder for a foreman to secure good daymen, because men can earn better money digging. A certain machinerunner who drew, on three successive paydays, $214, $170 and $186, asked the foreman to get another man in his place, claiming that his wife was sick. These are a few of the perplexities of mine foremen.

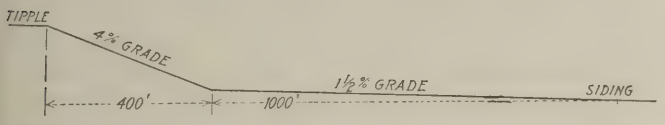
ANON.

INQUIRIES OF GENERAL INTEREST



Engine-Plane Haulage

Kindly allow me to present a problem with which we are confronted in our mining operations. It is in regard to a proposed engine-plane haulage, extending from a sidetrack in the mine to the tipple on the surface. As indicated in the accompanying profile, starting from the sidetrack there is an upgrade of 1½ per cent. for a distance of 1000 ft., to the foot of an incline having a grade of 25 per cent.

The incline, which is 400 ft. long, has been previously operated as an engine plane; but we desire, now, to drop the loaded cars from the top of the plane the entire distance to the sidetrack in the mine. The loaded cars weigh 5000 lb., and the empties 1500 lb., each. There are three cars hauled in a trip. The daily output of the mine is 500 tons. I want to ask if the proposed plan will work successfully; if not, please explain the method of finding the flatest grade we can use and the size of engine required for the work. W. M. Q.

———, Penn.

It is difficult to obtain a clear idea of what this inquirer has in mind when he asks for "the flatest grade that can be used." The situation, as we understand it and as illustrated in the figure, consists of a 25 per cent.

PROFILE OF A PROPOSED ENGINE-PLANE HAULAGE

grade, forming an incline 400 ft. in length and running from the tipple floor into the mine. From the bottom of this incline an entry runs to the dip, on a grade of 1½ per cent., for a distance of 1000 ft., to the side track in the mine.

The weight of a loaded car being 5000 lb., a three-car trip would weigh 15,000 lb. To handle this trip on a 25 per cent. grade, assuming a track resistance of, say, 20 lb. per ton of load hauled and using a factor of safety of 5, will require a ½-in. crucible, cast-steel haulage rope, weighing 0.39 lb. per foot.

The test of the system will come when the three-car, empty trip, weighing 4500 lb. is approaching the side track and must drag the entire length of the rope behind it. The gravity pull, less the track resistance of the empty trip, at this point, is only about 22.5 lb. The gravity pull of the entire length of rope on both grades, may be about 45 lb., which makes a total force of 67.5 lb., acting to drag the rope from the winding drum and over the rollers on the track.

It is difficult to say if this force is sufficient to overcome the rope friction without more definite data for estimating the resistance. One thing, however, seems certain and that is it would not be possible, in this system, to make the number of trips required to put out 500 tons of coal per day. A three-car trip would carry $3(5000 - 1500) \div 2000 = 5.25$ tons, which would require $500 \div 5.25 = 95$ trips or, say a trip every five minutes, hauling 8 hours a day. *Coal Age* submits this question for further consideration by its readers.

Mule Power in Mine Haulage

We are desirous of ascertaining what is a fair estimate of the work that a good average mine mule or horse will perform when working under average conditions, in a level seam. Also, how does the question of grade affect mule haulage? This is a matter on which I have been unable to find reliable information based on coal-mining practice; and, as the question has presented itself several times recently, I shall appreciate any assistance that is available. H. R. S.

Plymouth, Ohio.

The work that a mule will perform in a mine will depend not only on the size and weight of the mule and conditions regarding track, rolling stock, grades and headroom on the haulage road; but also on the character and skill of the driver, the length of haul and time lost in changing trips or waiting for loaded cars. It is clear, then, that this question is not solely one of how much a good mule can haul on a level track.

Observations taken, from time to time, in practically level seams and under fairly average conditions in coal mining, make the estimated work of an average mine mule about 6 or 7 ton-mile hours; that is to say, the average mine mule will ordinarily handle, say 200 tons of coal, on a quarter mile haul, in 8 hours. In other words, for an output of 1000 tons of coal a day, five mules would be required, on a quarter mile haul.

It is understood that this is only an average estimate based on fairly good coal-mining conditions in respect to the several items previously mentioned. The tractive power of a mine mule is commonly estimated as one fifth of its weight; and, taking the track resistance of the mine cars as, say 20 lb. per ton, or 1/100 of the gross load hauled, it may be assumed that an average mule will haul twenty times its own weight, on a level track. In other words, a mule weighing 8 cwt. may be assumed to haul a gross load of 8 tons, on a level track.

The tractive power of a mule, however, decreases rapidly with an increase of grade of track. A 3 per cent. grade should be considered as the limiting, uniform grade on which a mule should be obliged to haul, for any great time or distance. When a haulage road has a varying grade of ups and downs, the impetus given the trip on the downgrade will often permit a mule to haul the load up the upgrade following, without inconvenience, although that grade may exceed the limit of 3 per cent. just mentioned. The 3 per cent. limit applies only to a continuous upgrade.

EXAMINATION QUESTIONS

British Columbia Examination Second Class, Dec. 17, 1918

(*Selected Questions*)

Ques.—What is meant by diffusion of gases? Explain Graham's law of diffusion.

Ans.—The term "diffusion," as applied to gases, relates to the mutual intermixing of the molecules of two or more gases when in contact with each other. Diffusion takes place according to a fixed law known as Graham's law of diffusion. The law states that the rate of diffusion of gases into each other or into air varies inversely as the square root of their densities, or specific gravities when referred to air as unity.

For example, in the diffusion that takes place between a body of pure methane and air, the relative velocities of their molecules are as $\sqrt{1}: \sqrt{0.559}$; or 1: 0.748. That is to say, for every volume of the gas passing into the air, there will be 0.748 vol. of air passing over into the gas. The mixture resulting when diffusion first starts between pure methane and air will therefore consist of 1000 parts of the gas to 748 parts of air. The specific gravity of the gas mixed with air is at once increased to 0.748, and the diffusion is less and less rapid as the specific gravity of the mixture approaches that of air.

Ques.—Is it possible that an explosion of firedamp in a safety lamp would be of sufficient force to pass the flame through the gauze? Explain fully.

Ans.—If the firedamp mixture entering and filling the chimney of the lamp is inflammable only small balloons of flame will be seen to arise from the combustion chamber of the lamp and disappear in the gauze chimney above. But, if the mixture is within the explosive range of the gas more or less violent explosions will take place within the lamp. The violence of the explosion, however, will be greatly modified by the presence of the burnt air and gas accumulated in the upper part of the chimney.

As the mixture entering the lamp approaches more closely to the maximum explosive point of the gas, sharp crackling sounds will be heard and the violence of these explosions increases. If the lamp is not now cautiously and promptly withdrawn from the mixture, the explosive action continuing within the lamp will drive out the accumulated burnt air and gas from the gauze chimney above, and it is then possible for a violent explosion to occur within the chimney and force the flame through the mesh of the gauze and ignite the gas surrounding the lamp.

Ques.—How would you remove a large body of firedamp from a section of the mine where the ventilating current is insufficient, without unduly reducing the quantity of ventilation in other sections of the mine?

Ans.—The removal of a large body of firedamp from a section of a mine where the ventilating current is insufficient will require increasing the quantity of air circulating in that section. Before anything is done, however, safety demands the withdrawing of all the men from the mine, except those engaged in the work of removing the gas.

It is possible to obtain some increase in circulation in the gassy section, by robbing the circulation in other sections of the mine, without unduly reducing the quantity of air required to keep those sections clear. But, for a further increase of the circulation in the gassy section, recourse must be had either to increasing the speed of the fan or assisting the ventilation by removing any possible obstructions in the airways, and by erecting special brattices to deflect the air current against the accumulated body of gas.

Only experienced men equipped with approved safety lamps must be employed for this work. Sufficient time must be given for the air current to act upon the gas and frequent tests must be made to ascertain the progress of the work. In the meantime, the lamps in use must be guarded as much as possible against a sudden rush of air should a fall of roof take place in the section.

Ques.—To what are explosions in coal mines due? Describe the varying conditions that may cause or contribute to an explosion, and state what precautions you would take to prevent them.

Ans.—Explosions in coal mines result from the ignition of a body of firedamp or a cloud of dust floating in the mine air. The ignition may be due to contact with the flame of a naked lamp, a defective safety lamp, or the improper use of a safety lamp by an inexperienced person. Ignition may be caused by the blowing out of an electric fuse, sparking of wires or electric motors, the breaking of an incandescent lamp, a gob fire, the ignition of a gas feeder in blasting, and a number of other causes producing heat or flame.

The accumulation of gas in void places in the roof or in abandoned workings; or accumulations of fine inflammable dust at the working face and on the roadways; or the use of mixed lights in mines requiring locked safety lamps in one or more sections; or the excessive use of powder in blasting the coal and the lack of judgment and experience in placing shots: all present conditions that contribute to an explosion taking place in the mine.

In order to avoid the occurrence of explosions in mines, it is necessary to remove the causes that contribute to produce them. The workings must be thoroughly inspected for gas, both before the men enter their places for work and while they are at work. All shots should be inspected, charged and fired by competent shotfirers. All electrical installations should be made by competent mine electricians. The roadways and air-courses should be kept free from accumulations of dust. In machine mining, the cuttings should be loaded out of the mine. No fine coal or slack should be stored in the waste. Eternal vigilance is the price paid for safety.
